He found in the buccal coating and in the dental tartar eighteen different species of micro-organisms, and from these he succeeded in isolating seventeen. The eighteenth, which he did not succeed in isolating, was the *spirochete denticula*. The author, like his predecessors, did not succeed in finding a favorable medium for the cultivation of this micro-organism. Of the seventeen species which he cultivated, M. Vignal found that sixteen were aerobic and one anaerobic. Three of these micro-organisms are micrococci, thirteen are bacilli, and one is a vibrion. Seven of them have already been described by different authors: they are the *bacterium termo*, Koch's potato-bacillus, *bacillus subtilis*, *staphylococcus pyogenes albus* and *aureus*, and the leptothrix. Three others have perhaps already been observed; the coccus "*a*" of the author appears to have been seen by Miller in dental caries; the bacillus "*e*," perhaps described by Chyre and Cheshire under the name of *bacillus aluci;* and, finally, the bacillus "*e*," which is perhaps the *bacillus ulna*. But, as the descriptions which authors have given of these three micro-organisms are not sufficiently precise, M. Vignal abstains from giving their names to those he had seen.

In this first part of his memoir the micro-organisms which the author has met with are alone described, and he has given the description of them in different mediums of cultivation, in order that they may be recognized from the differential character presented by their cultivation. The author has tabulated the principal characteristics of the cultivation of these micro-organisms, in order that they may be easily detected by comparison. The memoir is accompanied with eight plates, which represent the aspects of these micro-organisms in the different mediums of cultivation, and the spots they form on gelatin. All these illustrations have been made on the same scale. Besides the plates, half-schematic figures are dispersed throughout the text, representing the aspect of culture-colonies in needle-holes in the peptonized gelatin contained in the tubes.

The first part of the memoir is, so to speak, but the introduction of a series of researches. For, in addition to the influence exerted by these micro-organisms on a few simple alimentary substances and the observation of the effect which the digestive fluids have upon the former, the author announces that he is about to begin researches concerning the micro-organisms in fæcal matter, and that he has already begun, in conjunction with M. Malassez (whose competence in pathological anatomy needs no comment), a series of researches on the action which these micro-organisms exert upon animals. When these researches, together with those which the author is making in collaboration with M. Malassez, shall have appeared, the results will be made known to our readers.

WHOOPING-COUGH.—A series of five cases treated with continuous inhalation of carbolic acid by means of a mask (worn from eight to twenty-four hours daily), with good results, is reported by Dr. Pick (*Deutsch. Med. Zeitung.*)

PHILADELPHIA, MARCH 19, 1887.

EDITORIAL.

PREVENTIVE INOCULATIONS.

AT a recent meeting of the Epidemiological Society of London, Mr. Willoughby read an important paper upon the prophylactic treatment of certain infectious diseases by the practice of inoculation. Certain of the facts therein emphasized, though perhaps familiar in themselves, acquire increased significance from the manner in which they are associated and presented. The two characters by which a large class of diseases are distinguished from all others are, first, the spontaneous extinction of the morbid process within a limited, often definite, time; and, secondly, the immunity against subsequent infection, more or less lasting and complete, which follows the attack. These two phenomena have been regarded as closely related, but until lately no rational explanation has been suggested. Nevertheless, the whole scheme of protective inoculation rests upon them as a basis.

The first condition of such an inoculation is that the virus used should be derived, directly or indirectly, from the disease it is intended to avert. Cow-pox protects against smallpox only because no specific difference exists between these two diseases; vaccinia being in all probability, as stated by Mr. Willoughby, smallpox modified by being passed through the cow. The second condition is that the disease is one that does not recur. All non-recurring diseases are, or are presumed to be, bacterial. The converse of this, however, is not equally true, as some diseases, such as septicæmia and tuberculosis, run on indefinitely, while others, as diphtheria and cholera, confer no immunity against subsequent infection. In these, therefore, there can be no successful preventive inoculation.

The method of direct inoculation with the unchanged virus is open to the grave objection that, however great the immunity conferred and however small the risk incurred by the individual, the disease is unchanged and retains its infectious qualities. The practice of smallpox inoculation and of ovination have always been found to raise the total mortality from the respective diseases.

The next step in the evolution of the process is vaccination. Jenner's operation is as yet the only instance of the application of this method. But, as Willoughby suggests, there is no reason why some animal should not be found to play for the sheep the part played by the cow for man. In truth, Dr. Klein's experiments with the disease at a farm at Hendon, which he called "Cameron's disease," lead to the conclusion that it stands in the same relation to scarlatina as cow-pox to smallpox, and that it may be possible to employ it in the same way. If so, this would be "vaccination" in every sense except perhaps the etymological one.

The method of Pasteur, the so-called "method of attenuation," is open to the same objection as inoculation, with the yet more serious one added that, as it is impossible to standardize the attenuations, they sometimes fail to confer any protection whatever, and at other times they have caused the death of the animal experimented upon. For this reason they cannot safely be resorted to in man, nor indeed, except under certain circumstances, can they be employed by existing methods with sufficient certainty as to the result in the case of the domestic animals.

A fourth method consists in the inoculation of the products of the development of the bacilli without the bacilli themselves. Low forms of life, such as those concerned in the process of fermentation,

putrefaction, etc., as well as bacilli formed in the fluids from which they grow, are associated with chemical products such as sepsin, which give rise, after absorption into the blood, to the condition known as septicæmia. In some cases, when these are accumulated to a certain point, as in alcoholic fermentation, further development of the organisms is arrested. It has been suggested that something analogous to this occurs in the so-called zymotic diseases, and that this may be invoked to explain the extinction of the febrile process. This accumulation of chemical products could not, however, explain the subsequent immunity, since such products would be eliminated, if the patient survived, in the course of a few weeks at farthest.

The experiments of Dr. Salmon, of the United States Bureau of Agriculture, with swine-plague lead to the inference that the products of the development of the bacilli of any such disease so modify the constitution of the bioplasm of the tissue as to render it incapable of again affording a pabulum for the bacilli. Further, since cells to which a special character has since been imparted tend, as in the case of carcinomata and other neoplasms, to transmit it to those to which they give rise in the act of proliferation, this inability to support the growth of the particular bacillus may persist for many years. Since, however, they probably tend to revert to their original character, susceptibility is sooner or later reacquired.

This latest method promises results of incalculable importance and of the widest application to the prevention of the infectious diseases of man and beast. In its practical application it is necessary to identify the specific bacillus, find a medium suitable for its cultivation, and finally to determine its thermal death-point or remove it by the Pasteur-Chamberland filter. The process is wholly free from the objections to which first inoculations and attenuations are open, seeing that the phenomena induced are those of the action of a poison, whatever it may be, actually antagonistic to the disease.

VOLUNTARY SUICIDES BY CHILDREN.

WITHIN a week the coroner has been called to investigate the deaths of two children in this city, both of whom, in all probability, committed voluntary suicide. A doubt is implied because the exact circumstances attending the death of each will never be known, as the only witnesses present were children younger than themselves, but circumstances point strongly to suicide as the only explanation. The vital impulse is so strong in childhood, and the idea of death so repugnant at this period of life, that voluntary self-destruction by children seems to strike us with horror as a manifestation of a peculiarly abnormal condition of society. Such an occurrence would be impossible in a community normally constituted, where the burdens of life are properly proportioned and equally divided. The physician, philanthropist, and political economist are equally interested in the problem presented by these unhappy occurrences, in which the question of insanity evidently does not arise, not because insane people do not hang themselves or because chidren do not become insane, but because the form which insanity takes in children is not suicidal mania.

The details, as they appear in the daily papers, are briefly as follows. Annie N., a motherless girl, twelve years of age, who bore upon her shoulders, unassisted, the reponsibilities of housekeeping as well as the care of younger children, had committed some childish peccadillo for which she had reason to anticipate corporal punishment from her father, of whose ministrations her previous experience had inspired her with a lively dread. When the father returned

from his work he discovered not only that his supper had not been prepared by the child, who had expected a beating, but also that she had been—to all appearances, at least—so wicked as at once to escape his fatherly correction and to break up his *ménage*, by hanging herself to a door-frame in their miserable dwelling. Among the annals of the poor could any be more melancholy than this? A child, with the responsibilities of womanhood thrust prematurely upon her, and daily engaged in a dull round of work beyond her strength, whose only incentive to right conduct consisted in the promise of a "licking" if she failed to attain a standard arbitrarily established by a paternal government! Can we wonder that such a child should seek to escape at any hazard from the accumulated miseries of her existence? Her death-bed may find no chronicler like that of Little Nell or Poor Jo, but her wounds are dumb mouths which appeal directly to the heart.

The second case was clearly one of imitation. A little boy, thirteen years of age, in good health and usually cheerful, having been much interested in the accounts of the former suicide, went into the cellar of his residence, and, fastening a rope to a beam, adjusted a loop round his neck, and deliberately swung himself into eternity. For this death the morbid demand for cheap, graphic illustrations in flashy papers must be held responsible.

Many children who saw the pictures of the little girl dangling in the frame of the door, with the fatal rope around her neck, will be unable to shake off the horrid representation, which for them possessed a veritable fascination; and for months to come it may remain the ruling idea. It has been repeatedly noticed that among adults the published account of some novel method of suicide has been followed by many imitators of the original; and a similar explanation of some epidemics of crime has been frequently given.

A PLEA FOR THE BETTER VENTILATION OF CHURCHES.

OF all public buildings in civilized communities, churches are notoriously inadequately ventilated. Apparently, in the minds of architects health and comfort are considered of secondary importance when compared with the technical details of structure. A well-known professor of chemistry of this city used to declare that he could tell, simply by his olfactory sense, whether the persons whom he passed on the street on Sunday had been to church or not. With him the odor of sanctity represented something substantial, and was not a mere figure of speech. City churches, subject to overcrowding, are usually furnace-heated: too often the air for the flues is taken directly from the cellar, in which there may be several more or less objectionable sewer-connections. Country churches, which happily are not open to this criticism, are, on the other hand, kept closed during the winter months as tightly as possible in order to economize fuel. The result is partial asphyxia of the congregation, which leads to complaints of droning sermons and drowsy hearers. Under such circumstances the system is prepared for an attack of bronchitis or pneumonia, which may be lighted up on suddenly going from the heated and vitiated atmosphere to the cold air outside. Occasionally some one faints and has to be carried out; and a correspondent of a religious journal thinks that the sudden death of ministers in the pulpit is attributable to the impure air. The question of the ventilation of churches is certainly deserving of more attention than it seems to have yet received.

Dr. William Hunt, of this city, recently met with a serious accident by a wagon knocking him down on the street and causing fractures of his clavicle and humerus and other severe bodily injury.

NOTES FROM SPECIAL CORRESPONDENTS.

LONDON.

THE College of Physicians of Edinburgh has set a good example by taking steps to found a Research Laboratory, for the use, in the first place, of its own Fellows, members, and licentiates, and after them of other investigators. A scientific superintendent is to be appointed, at the modest salary of two hundred pounds a year. Meanwhile, the members of the Council of the College of Surgeons in London appear to be unable to make up their minds as to the disposal of the Erasmus Wilson bequest: the memorial to which I referred in my last letter must have shaken the determination of the most opinionated members, for the Council, at its last meeting, determined to spend the comparatively trifling sum of fifteen thousand pounds on building operations for the extension of the museum. It is stated, with suspicious ostentation, that this modest expenditure is not to be taken to mean that the gigantic scheme to spend the whole Erasmus Wilson bequest on bricks and mortar, plaster casts, wax models, and preserved specimens in bottles has been abandoned, but it is hardly likely that it will be revived in its original crude form. The University of Cambridge, which is by no means wealthy, has voted ten thousand pounds for enlarging the physiological laboratory, and the College of Physicians in London will probably apply the small income arising from the Croonian trust fund, which, owing to new dispositions, is now much more valuable than formerly, to the furtherance of clinical and therapeutical research, so that the College of Surgeons will not fail in its duty owing to any want of good example. The Society of Medical Officers of Health has presented a memorial to the Council, praying it to establish a laboratory for instruction and research in bacteriology. A laboratory for pathological chemistry is also very much wanted. Either or both could probably be maintained at a very small cost.

Charles Dickens is generally credited with having been the first to use the novel for the purpose of exposing faults in our social system. "Oliver Twist" and "Nicholas Nickleby" were not only novels, but, to parody a famous definition of history, philanthropy teaching by example. Modern English novelists in search of a social sensation have, during the last decade, frequently built up their plots on the lunacy laws. Several lawsuits which have resulted in verdicts in favor of persons alleged to be insane, who have obtained damages against physicians for signing certificates of lunacy without due care, have still further operated to produce a mass of opinion in favor of an alteration in the law. This influence has been powerfully reinforced by the anxiety exhibited not only by ordinary practitioners, but by the majority of alienists in this country, to be more securely protected from the serious danger to which all are now liable,—of being called upon by a recovered madman, or more often mad woman, to defend in a court of law the truth of certificates given perhaps many years earlier. A case of this character was recently decided in favor of the medical practitioner, but not until he had been put to very considerable expense in defending the action. Although he obtained a verdict without difficulty, it is now reported that the plaintiff has appealed. For three years in succession the government of the day has introduced a bill to amend the lunacy laws; in 1885 and 1886 the resignation of the government involved the disappearance of the bill; and, as the political future is very uncertain, it is difficult to feel very sanguine as to the fate of the two bills introduced into the House of Lords on February 7, as the amending bill provides that no person shall be received or detained as a lunatic except under an order signed by a judge of a county court, a stipendiary magistrate, or a justice of the peace; the judicial functionary chosen in any given case will be bound to give notice to the alleged lunatic that he has been petitioned to make an order, may have a personal interview with the alleged lunatic if he thinks it desirable, and must grant such an interview if the alleged lunatic demand it. The countersignature of the judicial functionary is intended as a safeguard to personal liberty, and was undoubtedly framed in the interest of alleged lunatics; yet the chief opposition has come not from the alienists or the medical practitioners, who would be glad enough to shift the responsibility on to the broader shoulders of the squire or the county-court judge, but from the Commissioners in Lunacy in the interest of lunatics; they have contended that the publicity inseparable from the judicial inquiry would have the effect of leading the friends of persons afflicted with mental disorders to conceal the fact, and retain them at home until the chances of recovery had vastly diminished. Prompt treatment by skilled physicians is of the utmost importance to the afflicted individual, and it is well known that the prognosis becomes more hopeless with every succeeding month, until after a year but little hope remains. The late Earl of Shaftesbury, the great champion of the oppressed, felt so strongly on this point that he resigned the chairmanship of the Board of Commissioners in Lunacy, a position which he had held for fifty years, rather than appear to lend any sanction to the bill. A concession to these objections appears to have been made in the bill just introduced, for it is provided that in cases where the judicial signatory has satisfied himself that it would be prejudicial to the alleged lunatic, or dangerous to the

public, he need not give the notice mentioned above to the alleged lunatic. The bill therefore practically leaves everything to the discretion of the judicial signatory, who may be guided by personal timidity, or by the medical opinions, or by the private influence of friends, but certainly not by knowledge. Other provisions of the bill will have the effect of gradually reducing the number of private asylums, for no new licenses are to be issued, and the public authorities will be encouraged to provide accommodations for private patients. The second bill, introduced at the same time, merely codifies the existing acts of Parliament.

The Lettsomian Lectures at the Medical Society of London were delivered by Dr. Langdon Down, the senior physician to the London Hospital. He took for his subject the mental affections of childhood and youth, and brought out many facts of much general interest. Dr. Down reiterated his opinion that the congenital idiots of the more highly developed races often resemble, in their facial configuration at least, certain of the races which occupy a lower step in the scale of civilization; that they have, for instance, resemblance to the Malays, Mongols, or Negroes. He considers that the observation of this resemblance will be of great use in making a correct diagnosis and prognosis. As a working classification, he divides cases of idiocy into the congenital, the developmental, and the accidental. In determining whether a case is to be referred to the first class or one of the others, he finds the "ethnic" peculiarities of great value, since, on the whole, the congenital cases give the best results and can be educated up to a certain point, whereas the accidental cases are most disappointing, though the prognosis at the first glance appears so much better. He has found that an instrumental labor has far less influence than a prolonged labor in producing feeble-mindedness, and that neither consanguinity nor disparity in the ages of the parents has any influence, while hereditary weakness is most powerful. Some good examples of "idiots savants" were well worth hearing, and will be not only instructive reading, but interesting and here and there amusing, when they are published in full.

Professor Greenfield, of Edinburgh, recently, in a very obscure case of acute brain-mischief, with perforation of the tympanic membrane on one side, diagnosticated an abscess in the anterior part of the sphenoidal lobe; at his request Mr. Caird trephined in the temporal region, found the dura mater tense, with absence of pulsation, lymph beneath the dura mater, and, finally, after passing a Graefe's knife directly inward for at least an inch, he hit upon the abscess and evacuated two ounces of fetid pus, using a pair of drainage-forceps to enlarge the wound; a drainage-tube was introduced and the wound dressed antiseptically. The patient, a young man, aged 26, had made notable improvement in twenty-four hours, and was almost quite well in a fortnight. On the same side as the abscess there was well-marked optic neuritis, which rapidly diminished after the operation, so that at the end of twenty-five days Dr. Argyll Robertson, who then examined the eye, could only say that the disk was a little pale and flat and not quite sharply defined at the margins.

A discussion on the diagnosis and treatment of cerebral abscess took place at the Glasgow Medico-Chirurgical Society on February 11 and 12, but does not appear to have added much to current knowledge. Dr. William MacEwen mentioned a case of abscess in the temporo-sphenoidal lobe upon which he had operated with success. Mr. Barker, who had another successful case (with Dr. Gowers) about three months ago, is reported to have stated that nearly all intra-cranial abscesses originating in ear-disease were in the cerebrum, and that nine-tenths of the cerebral abscesses were in the temporo-sphenoidal lobe. Such abscesses, though not very commonly met with, are not extremely rare: for instance, Professor Greenfield said he met with about one case a year in the Edinburgh Infirmary, and Dr. Coats said that the number in Glasgow was proportionate, so that probably this operation, which appears to present no serious difficulties to the surgeon, will soon become comparatively frequent,—more especially as the first five cases (treated by Barker and Gowers, Schondorff, Trückenbrod, Greenfield, and MacEwen) have been so successful. Altogether, there seem to have been twenty cases recently in which the cerebrum has been incised or partially excised, with three deaths, two from shock and one from septicæmia.

In a discussion on renal surgery which has recently occupied the attention of the Clinical Society for two nights, much prominence was given to the difficulty of diagnosis. Mr. Bennett, of St. George's Hospital, related a case in which a tumor in the renal region was freely laid open through the loin, and the finger entered what was apparently a disorganized kidney. The patient died of lung-disease six weeks later, when the wound was almost closed, and it was found that the kidney was quite intact and that the cavity opened was an abscess. Mr. Knowsly Thornton, who advocates an exploratory abdominal incision to allow both kidneys to be examined, and then a lumbar incision for the removal of the stone and for drainage, mentioned one case where, owing to the patient being stout, it was even then difficult to feel the stone. Mr. Bruce Clarke mentioned a case of abdominal aneurism closely resembling renal disease, and several speakers referred to the additional difficulty created by the frequent reference of pain or colic to the opposite side.

The Hunterian Oration at the College of

Surgeons attracted the usual large audience, and Mr. Savory, the President, discoursed with more than usual eloquence on Hunter and his share in the foundation of a scientific system of surgery.

The homœopaths have scored their first important victory in London. There has been for many years a small infirmary for consumption in Margaret Street. It would seem that attention has recently been drawn to the fact that two of the physicians practised homœopathy. A meeting of the governors was held, and a resolution was proposed inviting these two members of the staff either to resign, or the one to remove his name from the Homœopathic Directory and the other to sever his connection with the Homœopathic Hospital. An amendment in an opposite sense was moved and carried by twenty against seventeen. The two consulting physicians, the surgeon, and four out of seven of the acting physicians have resigned. It is stated that the amendment was carried by the aid of the votes of governors who have only qualified within the last few months, and that the majority of the Executive Committee will resign.

The quarrel at the Liverpool Hospital for Women has ended, for the present at any rate, Dr. Imlach, the member of the staff who had performed the operation of "removal of the uterine appendages" so frequently, having failed to secure his re-election at the recent annual meeting of the "subscribers, donors, governors, and friends" of the hospital. Both sides had been active in obtaining proxy votes, but Dr. Imlach only obtained one hundred and thirty-seven proxies in his favor, while the proxies on the other side numbered three hundred and twelve. The voting of persons present at the meeting was more even, sixteen voting for and seventeen against Dr. Imlach.

A fund is being raised to perpetuate the memory of the late Dr. Walter Moxon; it is intended to place a memorial of him in Guy's Hospital, and to found a scholarship or medal to be awarded by the Royal College of Physicians.

Auvard's incubator has lately been used in the Glasgow Maternity Hospital in the case of three children (triplets) born at about the sixth month, or between that and the seventh; one died on the first day, another on the sixth, but the third survived and left the hospital with its mother, and has since continued to thrive. Though thus partially successful in this case, the apparatus appears to have been found very faulty in construction and inconvenient to work. Another apparatus, designed by a firm (Hearson) who manufacture chicken-incubators, was exhibited before the Medical Society here some years ago, and, as far as could be judged, was free from the chief objections to the French apparatus, which is simple but clumsy.

Total abstainers, not satisfied with having induced several life-insurance companies to institute a special section for them, started a Blue-Ribbon Company three years ago. The company pays a dividend of five per cent. this year, and the persons insured in the total abstinence sections of the other companies receive larger bonuses than the drinkers of alcohol.

Of the various schemes for providing London students with a degree on easier terms than at present, the one which appears to be making most progress is that of the College of Physicians and Surgeons. It is reported that the delegates of the two colleges meeting together have already begun the discussion of the charter which is to be obtained for the "University of Westminster." The committee of the Senate of the University of London appointed on Lord-Justice Fry's motion have agreed to a report recommending certain alterations in the constitution of the University, intended to give the teachers more power and to make the regulations more elastic; it will shortly be discussed by the Senate, and if adopted, as is said to be probable, there can be no doubt that the University will get a new charter. In that case we shall probably hear no more of the scheme about to be floated by University College: this is to obtain a charter for "an academical body in London, of which University College shall be the first constituent, such charter to give the right of conferring degrees in arts and science only." The last clause is no doubt directed to disarm the opposition of the medical schools. The scheme, as will be observed, would work in very well with the "University of Westminster" scheme.

The General Medical Council is in session, and the new members are beginning at once to make their voices heard. The Colleges of Physicians and Surgeons in Ireland had entered into the preliminary arrangements for constituting a conjoint board upon the same lines as the conjoint board in England, and it had been arranged that application should be made to the General Medical Council to sanction the scheme. The Apothecaries' Hall in Dublin objected to being left out in the cold, and it is understood that their representations have so influenced the College of Surgeons that the latter body is anxious to modify the scheme. The College of Physicians, however, will have nothing to do with the Apothecaries, and though the General Medical Council, when the matter came before it, passed a resolution "requesting" the College of Physicians to reconsider its decision, the probability seems to be that it will remain obdurate. The most curious fact is that the Council finds that it has no power to forbid the banns if any two corporate bodies choose to enter into combination: so that it would appear to be quite within the power of the College of Surgeons to combine with the

Apothecaries' Hall and leave the College of Physicians stranded,—a consummation devoutly to be deprecated.

Dr. Lutaud, the editor of the *Journal de Médecine* (Paris), has recently been in London, collecting evidence as to the cause of death in the patients of Pasteur who have died in England. He believes that altogether ten persons have recently died of "paralytic rabies" communicated to them by Pasteur's inoculation, and has, I hear, a volume in press designed to establish this contention.

The Rev. Dr. Dallinger, F.R.S., who has been again elected President of the Royal Microscopical Society, gave an account of some very curious experiments he has been making for the last seven years on micro-organisms. He began by growing certain moulds at a temperature of 60° F.; by very gradual stages he raised the temperature and noted the effect. When, after four months, he reached 73° F., the organisms began to show that their vitality was becoming depressed; after being kept at 73° F., however, for two months, they regained their vigor; and then by slow degrees the temperature was raised to 78° F. in five months more, when another pause became necessary. By continuing the experiment on these lines he finally reached the temperature of 158° F., at which the organisms were growing when an accident put an end to the research. The organisms which had been thus acclimated to 158° F. could not live at 60° F.

The fifteenth report of the Medical Officer to the Local Government Board contains much that is of interest to epidemiologists and pathologists. In a previous letter I have mentioned the epidemic of scarlet fever in London, which was conclusively shown to stand in some direct connection with a dairy-farm at Hendon, in Middlesex, and was believed, on grounds which amounted to a strong probability, to have been due to the prevalence of sore udders among the cows. There can now be no doubt that the sore udders were in reality the cutaneous lesions of an epizootic disease easily communicable by the discharges from the ulcers. Dr. Klein, F.R.S., has isolated a streptococcus from the ulcers on the udders, and, by inoculating calves with it, has produced in them a disease which, in the changes noted in the skin and kidneys, closely resembled human scarlet fever. Finally, from the blood of ordinary human scarlet fever Dr. Klein has succeeded in isolating a micro-organism which he considers to be identical with that obtained from the Hendon cow-disease.

The result of the researches of Mr. Power and Dr. Klein, while profoundly disquieting in one respect, ought to be of great use in another, for the local disease in cows, though apparently unaccompanied by any serious constitutional disturbance, could easily be recognized. The management of a dairy-farm is becoming more and more every day a matter of science. Dr. Klein's researches will probably meet with the more extensive acceptance, even from those who are accustomed to sneer at "germs," because they are entirely confirmatory of the theory started by Mr. Power on totally different grounds,—that is to say, after a judicial sifting of the evidence of the persons engaged on the dairy-farm and in the retail distribution of the milk.

Certain writers have striven to draw a distinction between what they call "bacillary tuberculosis" and "non-bacillary tuberculosis." The difficulty of discovering the bacillus in the tissues is often very great. It was early pointed out by Dr. Koch himself, and everybody who has worked at the subject has encountered the same difficulties; everybody, however, found that the disease could be produced by inoculation of material in which the bacilli were, to say the least, extremely difficult to discover. Dr. Klein and Mr. Lingan report a few experiments on this point. Certain sections were stained with care and the absence of bacilli established; other sections made at the same time — contiguous sections in fact—were used for inoculating guinea-pigs; the guinea-pigs became tuberculous and the lesions contained the bacilli. It follows, therefore, either that the bacilli or their spores were present in the original tissue in some unattainable and undemonstrable condition, as is the more probable, or that the inoculation of the tubercular material set up a process in the tissues favorable to the development of the bacillus, which it would in this case be necessary to assume must have found its way to the site of the lesion through the channel of the vascular system, just in the way the yellow coccus of pus must be assumed to reach a commencing focus of inflammation.

DAWSON WILLIAMS.

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA ACADEMY OF SURGERY.

MEETING OF FEBRUARY 7, 1887.

(Continued from page 392.)

DR. CHARLES K. MILLS: My observations in regard to hydrophobia have been entirely clinical or clinico-pathological in character. About six years ago, in connection with Drs. Seiler and Collins, I read a paper before the County Medical Society, reporting some cases with hydrophobic symptoms. I have paid considerable attention to the cases of so-called hydrophobia occurring in man. The conclusion which I have reached is that nineteen out of twenty of the cases which are supposed to be hydrophobia, as they occur in the human being in this city and as reported in the journals, can be easily ex-

plained upon some other hypothesis. This has only an indirect bearing upon the study of the question of the status of Pasteur's researches.

Dr. H. C. Wood: We have heard much discussion as to the question whether the virus is that of rabies, and whether there is such a disease as rabies. This seems to me of comparatively trifling importance. The facts brought before us by Dr. Ernst seem to establish a principle which may, in the future, entirely change our present methods of therapeutics. It is perfectly plain that when we give a man the vaccine disease we produce a disease which is followed by certain changes in the system which are supposed to be identical with those produced by ordinary smallpox, and therefore the man is protected from smallpox. But in the cases of the experiments which have been given here to-night the thing is not this at all. We have an animal which has a disease,—whether it be rabies or not, it is some disease given to it,—and then the disease is cured by the inoculation of other masses of the disease-material of less virulence or potency. There has quite recently arisen in Southern Europe a school of therapeutists which teaches that we are to cure smallpox, scarlet fever, and certain other diseases by inoculation of the same disease. I confess that I have never thought the matter worth investigation; but we are now in the presence of positive and scientific evidence that we can cure disease by inoculating with an attenuation of the poison.

I think myself that the common idea that a disease does not begin until we have its symptoms is a false one. The process is going on during the period of incubation, and the disease commences, I think, so soon as the system is inoculated with the poison. The stage of incubation is simply the stage in which there are no symptoms. It seems, if the statements of Dr. Ernst be accurate, that it is possible to cure bacterial disease by the inoculation of the same poison, and the outlook for the future is that the time may come when this will be the treatment of every one of our acute zymotic disorders.

Dr. J. Ewing Mears: Before Dr. Ernst is called upon to close the discussion, it seems to me proper to say that we are under the greatest obligations to him for coming to our city and presenting to us the results of his investigations. I am informed that these experiments have been made at the instance of the authorities of the Harvard Medical School. We are therefore under great obligations both to Dr. Ernst and to the Harvard University.

With regard to the subject so ably presented to-night, I think I can speak for every true surgeon in saying that, while we have much to do with it, we are in a condition of receptivity; we are waiting for these investigations to be carried to such a point and for the results to be so determined that the practical surgeon can take the material which may be finally isolated, and which can be used in the same manner as we use the vaccine virus to-day. That the time will come I have no doubt. It may take some years; but that the outcome of all this scientific work will be the advancement of surgical knowledge and of the art of surgery there can be no question.

That we should not accept without discussion the results of these experiments is perfectly natural. I think there is reason for objections, for the results of investigations by Pasteur, upon this subject,—not such as those made by Dr. Ernst, and by others, but in the gleaning of all the results which have been presented in the journals and in other ways. It may be well that there should be some one, and probably more than one, who will act as checks upon the enthusiasm of experimenters. The objections to-night will possibly be received as suggestions by Dr. Ernst and other investigators, and will stimulate them to avoid error. It may not be familiar to all present, but it is stated that the College of Physicians of this city nearly one hundred years ago failed to approve the nomination of Jenner as an honorary member of that institution. The originator of vaccination, who has probably done as much to save life as any man, and who has placed the whole human race under obligations to him, was evidently not deemed worthy of Honorary Fellowship by the few members who then constituted the College of Physicians. They thought, no doubt, little of his work, and considered his results fallacious. This was natural: it is in accordance with what we see to-day. These investigations are progressing, and the objections, the unbelief, the suspicions, if you choose, which are constantly suggested with regard to them will do good. I think that our friend Dr. Ernst will be gratified with the instructive discussion of his able and interesting paper.

Dr. Harold C. Ernst, who closed the discussion, presented a rabbit suffering with rabies, which he had inoculated ten days ago. He also exhibited the trephines which he uses in making inoculations under the dura mater. Dr. Ernst then said,—

Dr. Shakespeare has spoken of the change in the intensity of the opisthotonos. That, too, I have seen, and I think that it is included in the description which I have given of the symptoms. I have never seen opisthotonos cease entirely. With reference to the question of tetanus, very curiously the same thing happened to me. One of the dogs which I had inoculated died, and, by the carelessness of the janitor, was not immediately placed on ice. Material from this dog was used the next day to inoculate three dogs and two rabbits; they all died the following day with intense opisthotonos. I inoculated other animals, and they also died within

thirty-six hours. Upon momentary inspection the symptoms might be thought to resemble those of rabies, but the period of incubation was almost nothing, the animals dying within thirty-six hours. I at once recognized that I had an eruption of tetanus. My time was so occupied that I was unable to make special investigations upon this matter. The only way in which I can explain it is that the dog had undergone some putrefactive changes before being used for inoculation.

Dr. Dulles has made a number of criticisms upon my paper. He is good enough to say that there are certain points which he thinks I have proved, but when he sat down I was at a loss to find that I had proved anything. He makes a point that Pasteur asserts that his animals die on the seventh day. I think that Pasteur asserts that the symptoms appear on the seventh day; but this is a small point. With reference to the variation of the period of incubation, he makes it a point that one of the rabbits which I received was inoculated June 14 and died June 28. It must be remembered that that animal was taken on a sea-voyage; it might have been sea-sick. The other was inoculated June 21 and died July 4. These rabbits were of a different species from those we have here. The variation in the period of incubation might have been due to change in the surroundings, to change of temperature, and change of the conditions under which they were kept.

With regard to averages, if Dr. Dulles misunderstood me so far after having had an opportunity of examining these tables, I am unable to help it. The longest period of incubation was twenty-three days, and that was only in one case. I mentioned that, because, in an investigation of this kind, I think that it is absolutely necessary that every experiment be given, and then a candid critic can draw his own conclusions. There was only one case in which the period of incubation was three days. In the large majority of cases it was from twelve to seven days. In most of the cases the appearance of the symptoms was from seven to eight days, precisely what Pasteur states that it is. These averages are drawn from thirty-two cases. The same is true with regard to the other averages.

In regard to my statement with reference to the place Pasteur got his virus, the sentence in which this is mentioned is clumsily constructed; but I think if attention be given it will be seen that the idea I meant to convey was that Pasteur commenced his experiments on hydrophobia with the virus from the child who died of supposed hydrophobia, not that he began his protective inoculations with that virus.

In regard to the criticism that it is necessary to make a large number of subdural inoculations with other bacteria in order to prove that this is a specific virus, and that other bacteria will not produce these symptoms, I must say that I think this unnecessary for the very reason of the success of the experiments of the kind that I have detailed, especially those upon guinea-pigs. This is the most striking series of experiments of which I have any personal knowledge.

I am ready to agree with Dr. Dulles that Pasteur's statements do vary sometimes, and I do not wonder at it. He is pursued by investigators from all over the world, and a man occasionally says things in a hurry which may get into print. As the results of his experiments are from time to time tabulated for him, his opinions must change to some extent.

Here is the fact that in three hundred and fifty or four hundred inoculation experiments upon guinea-pigs made during the past few years, I have injected subcutaneously bacteria of all degrees of virulence from that of anthrax to the simple bacteria of suppuration or the ordinary bacteria of putrefaction, and I have obtained all sorts of results, but I have never seen anything which in the least resembled what was obtained in three out of ten of these guinea-pigs. There has never been anything that could be ascribed to the nerve-centres. That the application of these bacteria beneath the dura mater would have such an effect is not probable. It has been proved by these experiments that the healthy spinal cord so applied has no effect. My results correspond very closely with those of Pasteur in this respect. He states that thirty-three and one-third per cent. of the animals inoculated with the stronger virus die. I inoculated ten animals, of which three died and one had symptoms of paresis but recovered.

Dr. Dulles wishes to know how it is possible to have the virus ready at all times. This is perfectly easy. I have proved by experiment, and the rabbit exhibited to-night is a visible proof of this, that if the animal be properly frozen the virus will retain its strength for a period of at least six months. The rabbit before you was inoculated with the cord of a rabbit which was inoculated July 11, 1886, and died the latter part of the same month. It was frozen ever since until ten days ago. I have repeated this experiment a number of times. A large number of these experiments have been made with cords which have been kept frozen for periods ranging from two weeks to six months.

Dr. Dulles has laid great stress upon the large percentage of failures. My percentage has not been larger than in most experimental work. But I have given every animal that I have experimented upon, and have tried to explain the failures. He seems to think that this is a ground for refusing belief to Pasteur's results. It does not seem so to me. I have been working almost all the time by myself. I have not the large amount of money, and I have not many of the advantages, which Pas-

teur has. These things I have not the slightest doubt reduce his percentage of failures.

I began this work last summer as a sceptic, but I am now a firm believer in the truth of most of Pasteur's assertions.

There is still another point. Dr. Dulles wants to know how it is that we are certain that this virus is the poison of rabies. The experiments of Fritch prove this. He has inoculated rabbits, dogs, and guinea-pigs with so-called street-rabies, and has produced exactly the same symptoms as those produced by the virus obtained from Pasteur. He gives the confirmatory evidence which Pasteur's experiments have hitherto lacked.

In reply to Dr. Huidekoper, I would say that this is a series of sixteen successive inoculations.

In conclusion, I would say that I think that I voice the feeling of all experimenters when I say that criticisms of this kind are not justified unless they are backed by experimental evidence. Experimental research has in modern times come to such a point that a critic who undertakes to upset conclusions based upon hard work should offer hard experimental work in contra-evidence.

Adjourned.

JOINT MEETING OF THE PHILADELPHIA NEUROLOGICAL SOCIETY AND PHILADELPHIA MEDICAL JURISPRUDENCE SOCIETY.

JANUARY 24, 1887.

(Continued from page 390.)

DISCUSSION ON DR. DERCUM'S PAPER.

DR. THOMAS G. MORTON sent a note stating that he had been compelled to leave the meeting, and requested that the following letter be read, which he had received from Dr. Longstreth, Pathologist to the Pennsylvania Hospital:

"*Dear Doctor*,—In connection with the subject on which we were speaking,—the criminal insane brain,—let us remark, in the first place, that the examination of the brain of a person strangulated is a difficult one from which to draw accurate conclusions in respect to any of the more minute conditions, as well as in its gross aspects. Strangulation fills the brain with blood and serum, and makes it larger or heavier. These facts are well supported by authorities, especially Caspar in cases of suicide. The more prolonged the act of strangulation, the more marked are the alterations due to this cause.

"In respect to almost every alteration of tissue of the brain of an insane person, the same or similar alterations have been found in the brains of those about whom there has been no suspicion of insanity.

"Of the relation between the general conformation of the brain and insanity, it is to be remarked that no two brains present the same conformation, and that the two halves of the same brain are not identical. In the malformed brains, irregularities or deficiencies of the cerebral convolutions have been pointed out as occurring in the insane and in criminals; but no definite relation has been shown to exist between any particular portion of the brain and any definite form of insanity: that is to say, the defect or malformation of a convolution or group of convolutions has not been shown in connection with homicidal mania, dementia, melancholia, or general paralysis.

"In those cases, found among the criminal classes in England, in which defective brains have been considered as the cause of the criminal characteristics, the deformity of the brain seems to have been in all cases a matter of inheritance, and the criminal has in all cases been found to be defective in other respects, either physically or mentally.

"Very truly yours,

"MORRIS LONGSTRETH."

Dr. PARKER: I have had some experience in the examination of the brains of criminals, and I must say that the brain of Wilson was an exceptional one. The highly-developed superior external *pli de passage*, almost obliterating the parieto-occipital fissure in one hemisphere, makes it one of the most remarkable brains that I have ever seen. This brain was abnormally large, weighing, I believe, nearly fifty-eight ounces. The brain had grown excessively, and the walls of the skull were very thin. We have also transverse fissures running all the way through the hemisphere, cutting off the first, second, and third frontal convolutions, so that the precentral fissure is separated from the rest of the hemisphere. We also find a tendency to the formation of perpendicular fissures. This is a brain that has developed under pressure. The skull has not developed rapidly enough to permit of the normal development of the brain.

Dr. WILLIAM OSLER: We have had very definite statements in the public press that the examination of the brain of this unfortunate individual showed conclusively that he was insane. It is very evident from Dr. Dercum's account that this brain is of a low type, but the morphological formation does not indicate that the man was insane. It is a brain such as may be found in a pauper, and such as we know is not infrequently met with in criminals.

The evidences in regard to inflammation are not clearly brought out. The thickening of the membranes did not appear to be extreme. The adhesions between the dura mater and the skull and the thickening of the pia between the sulci do not appear to have been more marked than we see in other instances of persons who have shown no signs of insanity.

I would like to ask an explanation of the differences between the published statement and that made to-night. It is extremely unfortunate that these erroneous statements find their way into the public press. I do not know whether or not Dr. Dercum was responsible for them. The impression entertained by the community is that from the examination of Wilson's brain it was clear that he was insane. No such evidence has been brought here to-night.

Dr. CHARLES K. MILLS: Physicians are frequently misunderstood with reference to questions relating to the examination of the brains of those alleged to be insane. I have examined a large number of the brains of persons who have been insane, criminals, and persons of a low order, as found in large hospitals. We find in these brains a large number of malformations, conditions of congenital defect, and conditions of arrested development from mechanical or other causes. We have not sufficient data yet to say that this is the brain of a murderer, or this the brain of a man with the delusion of marital infidelity or hallucination of hearing, because the third frontal convolution is a little too small, or a little crooked, or a little too straight. None of us say anything of this kind; but we say that in an increasing degree we are adding to the data with reference to appearances of this kind, which show that a large number of these brains have similar anatomical defects and aberrations, and that is about all.

This brain, from the statements of Dr. Dercum, was a highly-deformed brain so far as the morphological appearances are concerned. It represented the conflict going on between overgrowth and pressure. It was also a diseased brain: it was diseased in its membranes, it was diseased on its surface, and also down deep in its internal portions. That is all we can say, and that is all any of us do say.

Dr. H. C. WOOD: There is no one for whose opinion I hold a higher respect than that of Dr. Osler, and I can only think that he must have misunderstood Dr. Dercum. Dr. Dercum stated that the man had pachymeningitis; that he had meningitis involving the pia mater and the adjacent membrane; that he had vascular destruction of the interior of the brain; that he had enlargement of the periganglionic spaces; and that he had enlargement of the perivascular spaces. That certainly indicates disease of the brain, and is entirely sufficient to produce insanity. I do not say that that condition of the brain proves that the person from whom it was taken was insane. I do say that that is an insane brain, and is a straw of evidence in favor of insanity during life. We are not at present able to connect insanity during life with pathological changes. There are enough pathological changes in this brain to account for insanity if it existed during life.

Dr. FRANCIS X. DERCUM: Dr. Wood has already said what I had intended to say with reference to the pathological conditions present here.

I am glad of the opportunity of explaining what I know about the newspaper reports referred to. I was called upon by a young man, a reporter of the press, and I dictated to him four or five sentences with reference to the exact condition of the brain. During the conversation he asked me if this, that, or the other condition would indicate insanity; but the only publication which I authorized was what I dictated to him, and of this I revised the manuscript. I was as much surprised as were others when I found what had been published. What I authorized the reporter to state was that I had a diseased brain to describe, and stated in general terms the condition present.

Dr. LEVICK: There is in the University Museum a bony cyst, the size of a hen's egg, which was removed from the brain of a young Frenchman who had committed almost every crime known. Many years of his life were spent in prison, and he narrowly escaped the guillotine. He was regarded as a criminal of the worst kind; but he was a good workman, and was not suspected to be insane. After his death this bony cyst, which had been pressing on the cortical structure for a long time, was found. I merely mention this because it has become the custom to sneer at the plea of insanity. It is well to remember that morbid conditions may exist within the cranium which are not obvious, and which, if known, might render the verdict in a given case different.

NEW YORK ACADEMY OF MEDICINE.

A STATED meeting was held February 17, 1887, the President, A. JACOBI, M.D., in the chair.

THE PRESIDENT read an address in which, after referring to the reform of sanitary abuses brought about by organization among medical men, and pointing out certain other desired reforms, he spoke at considerable length on the subject of medical advertising in the way of reportorial puffs in the newspapers. Since his reference to this subject over a year ago, fewer reports of wonderful operations, etc., had appeared in the papers, but the abuse was being revived. A pretended interview with himself was cited, picturing the dangers which would arise from digging up the streets in burying telegraph-wires, and, although he wrote to the editor denying having been interviewed, his letter was thrown into the waste-basket. Doubtless in many other instances physicians had been misrepresented; and under any circumstances such reports could but injure the individual physician and the profession at large.

SPASTIC ATAXIA (OR ATAXIC PARAPLEGIA) AND THE COMBINED SCLEROSIS OF THE SPINAL CORD.

Dr. C. L. DANA read a paper on this subject based on an analysis of over one hundred cases of Friedreich's disease, cases of combined sclerosis with mania, and cases belonging properly to the subject of the paper. Of the entire number of cases analyzed, in forty-five an autopsy had been made; of this number only sixteen were selected as falling in the class under discussion. To this sixteen he added eight seen by himself, in only one of which (a case of Dr. Graeme Hammond) an autopsy had been made.

The name ataxic paraplegia was objected to; indeed, the author knew of no name which was without objection. We might substitute the term, based on the pathology, combined fascicular sclerosis, were it not that there seemed to be cases in which this sclerosis was present while the symptoms during life had been those of locomotor ataxia with flaccid paralysis and not spasm.

Dr. Dana thought that most of the cases described as spastic paraplegia were apparently cases of tabes dorsalis upon which there had been added a disease of the lateral columns, especially of the pyramidal tracts, often of the direct cerebellar tracts. In his own experience, it did not seem possible always to draw the line between the cases in which the spastic symptoms predominated and those in which the sensory and paralytic symptoms predominated. He would divide the cases into those in which the background was a sensory one, resembling locomotor ataxia of a mild grade; second, those in which the fundamental features were spasm and paralysis, with ataxia superadded.

The following facts were drawn from his own cases and the sixteen in which autopsies had been made. Syphilis was rare, not amounting to more than five per cent.; heredity was an important fact; spastic ataxia even showed a family type. In cases occurring in early life, sexual and alcoholic excesses had been noted; in cases in which it occurred later in life it was due to hard physical strain and exposure. The disease begins usually with ataxia; then stiffness in the legs and trembling are noticed; sexual power early declines; then there appear temporary vesical disorders, generally retention or slowness in emptying the bladder. There also occur a feeling of numbness and pains of a fulminating character which do not last long. Patches of anæsthesia often go away under treatment. The muscle-sense is often good. Gastric and enteric crises are absent. The muscular spasm usually involves the lower extremities, but sometimes the arms. The gait is a combination of that of tabes and spastic paraplegia. The lesion is usually a sclerosis or degeneration of the long system-tracts in the cord,—namely, the direct cerebellar and pyramidal tracts and the columns of Goll,—but it might extend outward laterally, and the degree of involvement at different levels is not uniform. The part usually most affected is the upper dorsal.

Dr. M. ALLAN STARR agreed with Dr. Dana with regard to the difficulty of selecting a name, and thought the one offered by the author was open to the same criticism that he had made upon the name proposed by Gowers, and which Gowers had admitted to be bad. The pathological name, combined fascicular sclerosis, was objectionable because the sclerosis was not exclusively fascicular. The paper was a valuable one, yet he thought the picture of combined sclerosis of the cord was rather hazy. The pathological findings in Dr. Hammond's case were not those of combined fascicular sclerosis.

Dr. G. W. JACOBY thought we were working very much in the dark in trying to make a classification of cases from a clinical standpoint.

The same view was expressed by Dr. Birdsall and Dr. Brill, who thought that essentially the same lesion might give rise to different symptoms, according to the fibre-tracts involved in the cord. Dr. Seguin related a case with symptoms which would justify classing it among the cases referred to by Dr. Dana, and in which the lesion showed the gross appearances of sclerosis of the posterior and lateral columns, but the microscope showed that the lesion extended to the extreme lateral portions of the spinal cord, and was rather irregular at different levels. The President suggested that the irregular distribution of the lesion might be explained by its following the course of the very fine blood-vessels, as had been supposed some years ago by a German writer.

Dr. DANA said the clinical history of Dr. Hammond's case was typical of the class referred to; the lesions, however, illustrated irregular distribution.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

STATED MEETING, FEBRUARY 28, 1887.

The President, LAURENCE JOHNSON, M.D., in the chair.

THE DURATION OF THE SYPHILOGENIC CAPACITY IN RELATION TO MARRIAGE.

THE following were some of the conclusions at which Dr. MORROW arrived: 1. The facts of every-day observation showed that there was nothing constant in the contagion, nothing certain in the heredity of syphilis. Men sometimes married during the full activity of secondary syphilis and did not infect their wives nor transmit the disease to their offspring. But these negative observa-

tions were entirely valueless compared with the positive. 2. The passage of syphilis from the second to the tertiary stage, based on the anatomical appearance of the lesions, did not furnish sufficient criterion of the contagiousness or non-contagiousness of these lesions. 3. Clinical experience showed that late lesions were exceptionally, but none the less certainly, the source of the contagion. 4. While in the immense majority of cases the contagiousness of syphilis and its power of transmission ceased after the third or fourth year, yet there were well-authenticated observations to prove that these qualities sometimes continued much longer, and might be manifest the fifth or sixth year, or later. 5. The power of syphilitic parents to procreate diseased children might persist after the disappearance of symptoms. 6. The precise date in the evolution of the diathesis when the syphilitic organism underwent that change which marked the limit of transmissive power was not indicated with mathematical certainty. 7. The type of syphilis, the duration of its manifestations, the constitutional peculiarity of the patient, the character of the treatment, the presence or absence of certain conditions which were commonly recognized as factors in the gravity of syphilis, all exerted a modifying influence. 8. All these elements should be taken into consideration in deciding on the propriety of a syphilitic man's marrying. 9. Direct transmission from the father to the offspring, without the mother's becoming affected, could be classed among established facts.

Dr. Morrow referred to a paper by Dr. Otis, and said that he thought the conditions of admissibility to marriage formulated by Fournier were much broader and safer to follow. Indeed, the object of the paper was largely to prevent the evils which would result to the community should Dr. Otis's views be commonly accepted.

Dr. F. N. Otis had time to read but a part of a lengthy reply which he had prepared, knowing about what ground the paper would cover. He claimed that the inferences drawn from his paper by Dr. Morrow were not justifiable, for while he (Dr. Otis) had stated that his observation and that of others warranted the view that there was little danger of infection or transmission of syphilis after about the third year, yet he did not mean to license unrestricted liberty after that period. He held, however, that the reported cases of inoculation or transmission of syphilis after the fourth or sixth year, or later, were not only very few in number, but were unreliable, as other sources of contagion had not been excluded.

Dr. Otis believed that there were really only two stages of syphilis,—the infectious and the non-infectious. The first was characterized by cell-proliferation, the second by cell-destruction. Strictly speaking, the second stage was not syphilis; it was the sequelæ of syphilis, just as scarlet fever might have sequelæ after its infection had long disappeared. All authors admitted that syphilis did cease to be infectious or hereditary; it was only a question as to length of time. Few would refuse to give permission to matrimony after the fourth year; there were many who in certain cases would give it after the third year.

Dr. R. W. Taylor would be unwilling to be inoculated by lesions of syphilis, apparently secondary, although they did not occur until after the fifth or sixth year. But the contagious and hereditary property of the disease depended much upon circumstances, particularly upon treatment. If he could treat the patients from the appearance of secondary lesions to the end of the second year or second year and a half, he would be willing to risk that ninety-nine out of one hundred then marrying would escape affecting the wife or child. The virulence of syphilitic contagion gradually diminished: its exact duration could not be marked with mathematical certainty; it varied in different cases. He would not give his consent to a syphilitic's marrying before the end of two years. But if circumstances compelled marriage, he advised the prevention of conception and the employment of all safeguards against infecting the wife as long as the contagious element continued.

Dr. Bronson said the mother of a syphilitic child, the father having also syphilis, might be without lesions and still have syphilis. This was shown by the fact that the diseased child could not infect the mother, while it would a nurse.

ON THE SUPPOSED VIRUS OF CHANCROID.

Dr. F. R. Sturgis read the paper, in which he cited a number of experiments going to prove the position which he accepted,—namely, that there was no virus of chancroid. It was the result of an acute inflammation; its source, while frequently from another chancroid during venery, might also be from irritation in any other wound. Gonorrhœal pus, for instance, had given rise to the chancroid when applied to an abrasion or sore, and this chancroid was capable of auto-inoculation like any other chancroid. But its auto-inoculative property was usually less tenacious.

Dr. R. W. Taylor said the views of Dr. Sturgis to-day were those which Dr. Bumstead held almost alone in 1876, Dr. Taylor, however, having arrived at the same conclusions by independent investigation. He was glad to see that Dr. Sturgis had come over.

Dr. Otis accepted the views of the author of the paper.

Dr. Sturgis was not willing to admit having changed his views, but said that his paper this evening was only a continuation of an

article which he had published in the "Encyclopædia."

The special committee appointed to investigate certain charges against the Board of Health contained in the President's annual address reported that certificates of death had sometimes been returned requiring unnecessary changes. The sanitary superintendent, they thought, should have discretionary power to return certificates for correction or alteration, but it should be by special messenger or under seal, and not by word to the undertaker, to be delivered to the friends of the deceased, and by them to the physician.

NEW YORK PATHOLOGICAL SOCIETY.

A STATED meeting was held February 23, 1887, the President, T. MITCHELL PRUDDEN, M.D., in the chair.

PISTOL-SHOT WOUND OF THE BRAIN.

Dr. W. H. PORTER presented the brain of a man who had shot himself in the temple with a pistol of about .32 calibre. The ball passed directly through and out at the other temple, dividing in its course both middle cerebral arteries and breaking both orbital plates.

SURGICAL LIVER AND KIDNEY.

Dr. PORTER also presented the organs of a woman, aged about 22, who died about a week after laparotomy and removal of a hæmatoma by Dr. Emmet. The patient did well for five days after the operation, but the urine, which had previously been normal, showed increasing albumen and casts and specific gravity. Bad symptoms set in on the fifth day, ending fatally. The autopsy showed the wound in good condition, except a slight amount of suppuration along the sutures. There were no signs of peritonitis. There was extensive parenchymatous and fatty change in the liver, with some cirrhosis; a less degree of parenchymatous metamorphosis in the kidneys, and still less degenerative change in the heart. Dr. Porter thought the primary lesion leading to death was in the liver, that in the kidneys being secondary, and due to the poisonous elements thrown upon them from imperfect function in the liver and to want of nutrition. In a number of cases in which such changes had been found after anæsthesia for a surgical operation, there was no pus whatever in the operation-wound.

PRIMARY LESION IN THE RIGHT SIDE OF THE HEART.

Dr. PORTER also presented a heart removed from a man who had a history of rheumatism, jugular pulsation, a mitral and a tricuspid regurgitant murmur, and œdema. The specimen was interesting from the fact that it was rare to find the primary lesion upon the right side of the heart, as it seemed to be in this case. The right auricle was largely dilated; the ventricle was very small; there was tricuspid insufficiency; the mitral valves also showed marked insufficiency; there was also marked perihepatitis and patches of cirrhosis.

BILIARY CALCULI.

Dr. PORTER also presented the liver and a large blood-clot removed from the body of a woman, aged 32 years, who had always been healthy except at times during the past eight or ten years, when she suffered severe pain in the region of the liver. When admitted to the hospital she was jaundiced, had high temperature, and some tenderness in the abdominal region. General physical examination was negative. An hepatic abscess being suspected, aspiration was performed without result. Albumen and casts appeared in the urine the last few days of life.

The post-mortem examination showed numerous gall-stones in the gall-bladder and throughout the liver, eighty-six having been counted; the common duct was pervious, and all the ducts and gall-bladder were dilated. Dr. Porter thought it likely there had been a stone which oscillated back and forth in the common duct, obstructing the flow of bile, but which escaped unknown. He thought the stones had probably formed in the gall-bladder and backed up into the liver. An interesting feature in the case was the fact that capillary hemorrhage had occurred along the line of the aspirating needle, and within the peritoneum, between the liver and the diaphragm, there was a large blood-clot. The kidneys had undergone parenchymatous change, and there was endometritis and cystic degeneration of the ovaries. There was extensive parenchymatous and granular destruction of the liver, and slight cirrhosis. The heart-muscle was fatty.

EXSECTION OF THE HEAD OF THE FEMUR.

Dr. L. H. SAYRE presented the head of the femur removed from a boy, aged 13 years. His family history was good, and his health had been good, but he had, as his sister stated, always walked as if on a wooden leg. Three years ago he fell, and two years ago his lameness increased, but he was again able to walk as well as ever until about six weeks ago, when there was pain in the hip. Dr. Sayre thought it probable there was disease of the acetabulum. Lately deep-seated fluctuation was discovered over the enlarged gluteal region, and an exploratory excision gave exit to about four ounces of pus. No débris being in the pus, and there being no crepitation, it was a question whether to go on and excise the joint. Some gelatinous matter was extruded on manipulation, when it was decided to excise the joint. The ligamentum teres was gone, the acetabulum was perforated to the internal periosteum, the head of

the femur was perforated, the neck showed considerable disease. The patient was doing well since the operation.

ABSCESS OF THE LUNG SIMULATING EMPYEMA.

Dr. L. E. HOLT presented the lung of an infant, aged 3 weeks, which he first saw October 23, when it had been three days ill with pulmonary symptoms. Dr. Holt found signs of broncho-pneumonia in the lower lobe of the right lung. The temperature remained elevated to nearly 103° for eight days, and then fell. The changes at this time were similar, but more pronounced than at the first examination. He saw the child about ten days later, when he was informed that it had been doing well, and had gained flesh, but that the temperature had gone up the night before. There were now unquestionable signs of fluid over the lower lobe of the right lung, and to their astonishment the aspirator-needle withdrew pus, pointing to empyema. Three ounces were withdrawn. The line of flatness changed with change of position. The temperature fell, and continued down to about the second week, the child doing well. There was apparently little tendency to reaccumulation of fluid. The needle was again introduced, but only an ounce of pus could be withdrawn. Dr. Holt did not see the child again during life, but was told that three or four days later the temperature went up, and there was dyspnœa. The house-physician introduced the aspirator-needle at two places, but found no fluid. The autopsy showed the right lung occupying nearly the entire chest-cavity. In its lower lobe was a large fluctuating mass, found to contain four ounces of pus. No fluid in the pleural cavity. There were some patches of pneumonia in the upper lobe of the right lung. The lower lobe of the left lung was collapsed. The abscess-cavity seemed to be surrounded by dense fibrous tissue.

Dr. FRANK FERGUSON had recently found a similar abscess-cavity in the lower lobe of the lung of an adult. Close search showed that it communicated with a bronchial tube.

STRICTURE OF THE ŒSOPHAGUS.

Dr. FRANK FERGUSON presented the œsophagus of a child, aged 2 years, which had swallowed a small quantity of caustic potash about three months previously, and had since then been unable to retain anything on the stomach. Its condition did not permit of an operation when it entered the hospital. Nourishment was given by the rectum. The stricture was found on autopsy to be about midway of the length of the œsophagus, and scarcely admitted a match. The organs were anæmic.

THE death of M. Béclard, Dean of the Paris Faculty, and Professor of Physiology, at seventy-five years of age, has been announced.

REVIEWS AND BOOK NOTICES.

SŒUR JEANNE DES ANGES, SUPÉRIEURE DES URSULINES DE LOUDUN (XVII^e Siècle). Autobiographie d'une Hystérique possédée, d'après le Manuscrit inédit de la Bibliothèque de Tours. Annoté et publié par les Docteurs GABRIEL LEGUÉ et GILLES DE LA TOURETTE. Préface de M. le Professeur CHARCOT. Paris, 1886.

This is the latest of the publications of the *Progrès Médical* belonging to the Bibliothèque Diabolique, Collection Bourneville. In the public library of Tours is a book belonging to the middle of the seventeenth century, in manuscript, the title-page of which is (translated) as follows: "The Story of the Possession of Jeanne des Anges, Mother-Superior of the Ursuline Convent at Loudun." To extracts, which are evidently authentic, from the original diary and correspondence of Sœur Jeanne are added the reports of several investigations and trials, giving an insight into the workings of disordered physical and nervous organizations, which found expression in fancied supernatural possessions, and even in imaginary impregnation and suicidal impulse. The light which has been thrown upon the obscure manifestations of hysteria by Charcot enables us to understand the pathology of demoniac possession. Nowadays, instead of resorting to exorcism, we treat the physical disorder underlying it, as happily expressed by the poet Bunthorne: "All can be set right by calomel."

ON THE DISORDERS OF DIGESTION: THEIR CONSEQUENCES AND TREATMENT. By T. LAUDER BRUNTON, M.D., D.Sc., F.R.S., etc. London, Macmillan & Co., 1886. 8vo, pp. 389.

The Lettsomian Lectures on Disorders of Digestion, their Consequences and Treatment, delivered by the author in 1885, are the *pièce de résistance* in the volume before us, in which the author has included reprints of various articles upon allied subjects prepared and published by him at various times since January, 1873.

The author intends that these papers shall be read singly, at odd half-hours, rather than consecutively, since there is some unavoidable repetition, which, however, is justified by the importance of the lessons which they teach.

A MANUAL OF PRACTICAL THERAPEUTICS, CONSIDERED WITH REFERENCE TO ARTICLES OF THE MATERIA MEDICA. By EDWARD JOHN WARING, C.I.E., M.D., etc. Edited by DUDLEY W. BUXTON, M.D., etc. Fourth Edition. Philadelphia, P. Blakiston, Son & Co., 1886. Post 8vo, pp. 666.

Owing to physical disability, Dr. Waring secured the services of Dr. Dudley W. Bux-

ton, Assistant to the Professor of Medicine at the University College, London, as editor of the fourth edition of this well-known work on Therapeutics. By condensing and curtailing some of the old material, space has been found for notices of the principal new remedies which of late years have received professional endorsement. The work is alphabetically arranged; the articles are confined to the discussion of the definition, dosage, medical properties, and uses of the various drugs now employed in medicine, upon the basis of the British Pharmacopœia. American students will find it useful as an addition to their usual text-books, as it contains, in a form convenient for reference, an epitome of modern therapeutics.

NEW REMEDIES AND CLINICAL NOTES.

PRURITUS PUDENDI.—Parvin, in eczematous inflammation, recommends poultices and alkaline washes, followed by a powder of starch and oxide of zinc, or the subnitrate of bismuth, or an ointment of white precipitate. Constitutional treatment, a milk diet, and the use of Fowler's solution will be beneficial in most cases.

In ordinary pruritus hydrocyanic acid is one of the best applications to relieve the itching. Levrat recommends the following formula:

℞ Plumbi acetatis, 1 G.;
Acid. hydrocyanici dilut., 2 G.;
Aquæ, 20 G. M.

If excoriations exist, the following may be applied:

℞ Balsami Peruviani, 2 G.;
Ol. amygdalæ dulcis, 3 G.;
Acaciæ, 4 G.;
Aquæ rosæ, 15 G. M.

If the disease be parasitic in origin, a mixture of equal parts of sulphurous acid and glycerin may be applied, or a sulphur-bath taken. Finally, a six- to ten-per-cent. solution of cocaine muriate may be brushed over the irritated surface. Hot applications are sometimes very effective; others find more relief in ice-water compresses.—*College and Clinical Record.*

NAPHTHALIN AS A VERMIFUGE.—A Russian physician, Dr. Koriander, recommends naphthalin as a tænicide. To children of from one to three years from two to thirty grains, or to adults from twenty to ninety grains, daily, were given, in tapeworm, with successful results.

EXTRACT OF OPIUM FOR LOCAL USE.—The extract of opium, according to Dr. E. R. Squibb, is a convenient preparation for external or enepidermic anodyne application. It is to be moistened with water to a semi-liquid consistence, and spread very thinly upon oiled silk or adhesive plaster.—*Ephemeris*, January, 1887.

MISCELLANY.

PROGRESS OF CREMATION IN NEW YORK.—The most convincing sign which could be given of the interest felt in cremation in this country is given in the annual report of the New York Cremation Society. This Society owns the crematory at Fresh Pond, New York, and is the most successful of all the associations in this country. It has now one hundred and ninety members, of whom one hundred and thirty-two are active, and twenty-two have been added during the year. The company is out of debt, but needs money to carry on its work. On this point President William J. Flagg said, "During the year just ended we have more than held our own as to members and in resources. Aside from this, it has been a year of inactivity—call it a year of waiting, of waiting on events and developments—at the Fresh Pond Crematory. Our waiting is not yet ended, for the Cremation Company has had and still has its own troubles. Nevertheless, it has made a good record, having performed eighty-four incinerations during 1886, which compares well with that of any similar institution. If now it finds itself embarrassed for lack of reserved funds, and is obliged to ask for a moderate contribution in the form of a temporary loan from friends of the cause such as are here to-night, its prospects must not be thought discouraging. The company may well claim such trifling aid. Its managers have done their whole duty in digging their way up out of the material and financial ruin into which it tumbled so suddenly one day. The company now owns a crematory not elegant, but sufficient for all practical purposes, and is out of debt."

The amount of money needed was said to be two thousand five hundred dollars; the earnings of the crematory during the year were two thousand one hundred dollars.

In regard to the progress of the cremation idea Mr. Flagg said, "Cremation has gone quietly into operation without opposition or hinderance from any source, and without serious difficulty as to practical details. That an entire change in the customs of a people in the important and solemn matter of disposing of the dead should have been allowed in this way is certainly creditable to modern toleration. Considering that yet it is but a feeble minority that prefer to give their bodies to the element of fire to purify and consume, instead of giving them to foul the other three elements, we must admit that it is very generous of the majority to let us have our own way, which we trust will soon be the way of all."

ALEXANDER'S OPERATION.—Prof. Thomas A. Ashby, at the meeting of the Baltimore Academy of Medicine held February 1, 1887, read "A Contribution to the Study of the Operation of Shortening the Round Ligaments of the Uterus in Cases of Posterior Uterine Displacement, as originally performed by Dr. William Alexander, of Liverpool, in 1881." One case is reported in Dr. Ashby's paper, the result being a remarkable success. After considering the steps of the operation, he offers the following conclusions:

1st. The round ligaments are designed to hold the uterus in its axis in the pelvis and to draw the fundus of the organ towards the symphysis pubis. They have little, if any, sustaining power in preventing procidentia, except in extreme degrees of descent, where the organ has escaped external to the vulva. Posterior displacement of the uterus can only take place when the round ligaments have been relaxed or stretched by prolonged tension.

2d. Shortening the round ligaments is a practical method by which the uterus may be lifted into its normal axis, and be retained in position by a restoration of its normal supports.

3d. This operation is admissible in all cases of posterior displacement where the uterus is not fixed by adhesions, but perfectly movable in the pelvis, and where other methods of support are not of service.

4th. The operation can prove of little value in cases of procidentia, except when employed in conjunction with other methods instituted to overcome this form of displacement.

5th. The operation can be easily performed by one who is familiar with the anatomy of the parts. It is almost devoid of danger if ordinary safeguards are employed.

6th. In the class of cases to which it is limited, the benefits secured are striking and important.

LEGISLATION NEEDED TO PREVENT RAILROAD MISMANAGEMENT AFFECTING FOOD-SUPPLY.—The transportation of cattle is one of the questions which should concern the philanthropic and which ought to receive the attention of State Legislatures. The recent severe weather in the West has delayed railroad-trains greatly, and one of the most serious results of the storm is the loss of cattle coming from Texas to Chicago.

There have been many deaths which have been attributed to the bitter cold. It appears, however, that many of the cattle have had no food or water during their transportation, and a delay of only twelve hours might cause great mortality, even if there had been no storm at all.

It is barbarous to crowd cattle into small, poorly-ventilated cars, and then leave them without food and water for a period of from twenty-four to seventy-two hours. It is no wonder that many died when the trip was a little longer than was expected. It seems strange that cattle-owners should be willing to take the risk of loss, even if no sentiments of humanity prompted them to take care of their cattle. Yet such is the case, and perhaps nothing can be done until the Legislatures step in and require owners, under heavy penalties, to supply proper food and water for cattle while being transported. Such legislation would be as popular as it would be beneficial.

RESTRICTIONS UPON THE SALE OF ALCOHOLIC LIQUORS.—According to the statements of the Attorney-General of Kansas in his recent report to the Governor of that State, prohibition is a great and acknowledged success. The only drawback is that the drug-stores have taken the place largely of the saloons, and now retail liquor in much the same way that the saloons did. The law which permitted the drug-stores to sell liquor is a necessary one, and yet some way must be devised to keep the druggists within bounds. The Attorney-General asks to have the laws made more stringent, and suggests that the druggists be obliged to state under oath that the persons applying for liquor were known to them. The applicant must also sign his proper name instead of a fictitious one.

The principal piece of temperance legislation recently has been the decision of the Supreme Court of Ohio that the Dow tax-law is constitutional. This law places a tax ranging from two hundred dollars upward on all saloons, and will no doubt considerably reduce the number of saloons, while at the same time it brings in a large revenue to the State.

DEATH FROM BROMIDE OF POTASSIUM.—Eigner reports in the *Wiener Med. Presse* a death from chronic bromism. The patient was a girl, 19 years of age, who became epileptic at the age of six, in consequence of fright. She had taken bromide of potassium without medical advice for about a year, beginning with a small dose, but increasing it rapidly until, for some weeks, she had been taking two teaspoonfuls of the salt a day. The epileptic attacks ceased, but the patient began to grow weak and irritable, was unable to sleep, had vertigo, difficulty of vision and slowness of speech, and lost her memory. There were salivation, foul breath, and an eruption of acne on the face and over the entire body. The author calculated that the girl had taken over three pounds of the drug in the course of a year. She was admitted to hospital, but no improvement followed; she became delirious, and finally died. Just before death, signs of a commencing pneumonia at the base of the right lung were discovered; but, while this perhaps hastened the fatal termination, death was inevitable, and was evidently attributable to bromism.

While chronic bromism is not rare, it has seldom been the cause of death.—*Druggists Circular.*

THE ARCHIVES OF PEDIATRICS, edited by William Perry Watson, M.D., a monthly journal devoted to the diseases of infants and children, is now published by the J. B. Lippincott Company. The same general plan followed in the editorial department in the past will be continued,—viz.: I. Original Communications. To this department contributions have been promised by all the prominent teachers and writers on pediatrics in this country and in Europe. II. Current Literature. In this department it is intended to present from month to month a brief practical *résumé* of all the current pediatrical literature of the world,—information that it would be impossible for the busy practitioner to obtain without great cost and an immense loss of time. Drs. And. F. Currier and L. E. Holt, of New York, and Dr. John Van Vorst, Jr., of Jersey City, will continue their connection as collaborators. Subscription price, three dollars per annum. Address of editor, 319 York Street, Jersey City, New Jersey.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.—All who propose to read papers before this Society at its next session, to be held in Bedford, June 29, should *at once* send title and a brief abstract of the same to Dr. S. H. Gump, Chairman of Committee of Arrangements, Bedford.

WM. B. ATKINSON,
Permanent Secretary.

AT the annual examination of the students of the Philadelphia School of Anatomy, the "Henry C. Boenning Gold Medal," for proficiency in anatomy, was awarded to Mr. Manley F. Gates, of Elmira, New York, attending the Medico-Chirurgical College.

PROF. HUNTER MCGUIRE, of Richmond, Virginia, will deliver the annual oration—subject, "The Progress and Development of Medical Science"—before the Alumni Association of the Jefferson Medical College on Monday evening, April 4, 1887. A reception will be held after the lecture.

PROFESSOR JOHANN RUDOLPH RANKE, of the University of Groningen, recently died from the remote effects of blood-poisoning, contracted eighteen months ago.

DR. S. SOLIS-COHEN has removed to 219 South Seventeenth Street, Philadelphia.

NOTES AND QUERIES.

OBITUARY.

WILLIAM S. LITTLE, M.D., of Philadelphia, died at Aiken, South Carolina, February 17, in the thirty-ninth year of his age. He had achieved considerable reputation as an ophthalmologist, and was a member of the American Ophthalmological Society and other societies. He was a graduate of Princeton, and of Bellevue Hospital Medical College, and later of the Jefferson Medical College, in which for the last ten years he served as chief assistant to the Eye-Clinic. He had also studied his specialty in Europe. In spite of failing health, he devoted himself assiduously to his practice, and was a valued contributor to the medical journals. For many years he had been ophthalmic surgeon to the Church Home at Angora, in which he was greatly interested. He leaves a wife, the daughter of Dr. Ellwood Wilson, and five children.

OFFICIAL LIST

OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U.S. ARMY FROM FEBRUARY 27, 1887, TO MARCH 12, 1887.

MAJOR C. H. ALDEN, SURGEON.—Ordered for duty at U.S. Military Academy, West Point, New York, August 28, 1887, relieving Lieutenant-Colonel Andrew K. Smith, Surgeon, who will then report by letter to the Surgeon-General. S. O. 52, A. G. O., March 5, 1887.

MAJOR CHARLES R. GREENLEAF, SURGEON.—Ordered for duty in the office of the Surgeon-General of the Army. S. O. 41, A. G. O., February 18, 1887.

MAJOR D. L. HUNTINGTON, SURGEON.—Will be relieved from duty in the office of the Surgeon-General, to take effect March 1, 1887. S. O. 41, A. G. O., February 18, 1887.

MAJOR DAVID L. HUNTINGTON, SURGEON.—Ordered for duty at San Diego Barracks, California, and granted leave of absence for one month from March 1, 1887. S. O. 45, A. G. O., February 25, 1887.

CAPTAIN ROBERT H. WHITE, ASSISTANT-SURGEON.—On being relieved by Major Huntington, to proceed to Angel Island, California, and report to commanding officer for duty at that post. S. O. 45, A. G. O., February 25, 1887.

CAPTAIN WILLIAM F. CARTER, ASSISTANT-SURGEON.—Granted leave of absence for one month on surgeon's certificate of disability. S. O. 25, Department of Texas, February 24, 1887.

CAPTAIN GEORGE MCCREERY, ASSISTANT-SURGEON.—Leave of absence extended one month. S. O. 52, A. G. O., March 5, 1887.

CAPTAIN WILLIAM W. GRAY, ASSISTANT-SURGEON.—Leave of absence for seven days is extended twenty-three days. S. O. 13, Department of Dakota, February 21, 1887.

CAPTAIN R. W. JOHNSON, ASSISTANT-SURGEON.—Ordered for temporary duty at U.S. Military Academy, West Point, New York. S. O. 51, A. G. O., March 4, 1887.

FIRST-LIEUTENANT GUY L. EDIE, ASSISTANT-SURGEON.—Granted leave of absence for one month, to take effect about March 1, 1887. S. O. 27, Department of Texas, February 28, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U.S. NAVY FOR THE WEEK ENDING MARCH 12, 1887.

SURGEON GEORGE B. BRADLEY.—Detached from Naval Hospital, Philadelphia, Pennsylvania, and granted six months' leave.

PASSED ASSISTANT-SURGEON JOHN W. STERLE.—Ordered to Naval Hospital, Philadelphia, Pennsylvania, without delay.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U.S. MARINE HOSPITAL SERVICE FOR THE SIX WEEKS ENDED MARCH 12, 1887.

GUITÉRAS, JOHN, PASSED ASSISTANT-SURGEON.—Granted leave of absence for twenty-one days, February 28, 1887.

PETTUS, W. J., ASSISTANT-SURGEON.—To proceed to Charleston, South Carolina, for temporary duty, February 28, 1887.

BANKS, C. E., PASSED ASSISTANT-SURGEON.—To proceed to Chicago, Illinois, and assume temporary charge of the Service, March 10, 1887.

PHILADELPHIA, APRIL 2, 1887.

ORIGINAL LECTURES.

CLINICAL LECTURE

ON A CASE OF FETID BRONCHITIS SIMULATING ABSCESS OF THE LUNG CURED BY THE OIL OF SANDAL-WOOD; AND ON A CASE OF TUMOR OF BRAIN WITH CROSSED PARALYSIS.

Delivered at the Pennsylvania Hospital, January 22, 1887,

BY PROF. J. M. DA COSTA, M.D.

GENTLEMEN,—This patient is about leaving the hospital to return to his work, and I will now lay before you the results of his treatment. He is about 32 years of age, and has been much exposed to fumes of nitric acid in some chemical works. He had articular rheumatism five years ago, and chills and fever twice within the last two years. He drinks whiskey steadily, but denies excess. He was admitted into the hospital December 16, with cough and profuse expectoration, sometimes bloody and offensive. He had emaciated greatly, complained of poor appetite, diarrhœa, and had vomited several times. He had frontal headache, and sweated freely at night. Altogether it was a very unpromising case.

Upon examination there was found, about the middle of the left lung posteriorly, some dulness on percussion, and, upon placing the stethoscope to the chest, moist râles and faint pectoriloquy could at times be obtained.

All this, however, was but a repetition of a previous note, for the man had been in the hospital last September in a very similar condition, and so great at that time was the amount of the expectoration, containing masses of purulent matter, that the idea of abscess of the lung was seriously entertained. He was somewhat benefited by treatment, and went out, only to return with the same symptoms; and, indeed, there is no evidence that they had ceased from the time that he was in the hospital. When he returned were found again the cough, fetid expectoration, nummular sputa, emaciation, and sweating, and other features which had given rise to the supposition of abscess of the lung.

When readmitted, he had a slight rise in temperature (100°); pain in his left side; frequent expectoration of offensive purulent matter, amounting to a pint and a half in twenty-four hours, occasionally blood-streaked. The sputum was examined microscopically, but no bacilli and no elastic tissue could be found.

Now, this man, with all the signs of constitutional disturbance, emaciation, sweating, and the like, with all the signs of disease of the left lung, was submitted to systematic treatment and carefully-regulated diet. He was given carbolic acid, and subsequently terebene by inhalation, and other agents; but none of those tried and retried gave any enduring results. I then thought of what I had used before in cases of profuse expectoration, and especially in bronchial catarrh with offensive discharge, as in fetid bronchitis, and I placed him upon the oil of sandal-wood, at first five minims three times daily, and afterwards five times daily. The results were most striking. After about a month's treatment the expectoration has almost ceased; he now expectorates no more than a drachm in the twenty-four hours. The dulness at the lower part of the lung is no longer to be perceived, his breathing is better, the râles have disappeared. There are no physical signs other than a little harshness of breathing at the point indicated.

I will not discuss the diagnosis of this case. I do not think that there was really an abscess, but that there was bronchitis with dilatation and accumulation simulating an abscess. I do not propose to go into this more particularly, but merely show him to you and direct your attention to the oil of sandal-wood as an agent acting decidedly upon the mucous membrane of the bronchial tubes. Its effects upon other mucous membranes, as in the genito-urinary tract,—as in cases of purulent urine from disease of the kidneys,—first led me to use it for the condition of bronchorrhœa. It has afforded great relief to such cases in my hands. I may say that this man was cured by the oil of sandal-wood; and I think it worthy of your consideration in connection with other resources for the treatment of chronic bronchitis, with or without fetid expectoration, to which I have already called your attention.

CROSSED HEMIPLEGIA DUE TO BRAIN-TUMOR.

The next case to which I will call your attention is a more protracted one, though less rare than the one you have just seen. This is a boy, 15 years of age; birthplace, Brazil. His mother, brother, and sister, he states, are healthy and strong. His father was killed. We found no evidence of inherited syphilis, and he informs us positively that there is no acquired venereal taint. He was always healthy until about a year ago. He went to school, but sometimes worked at mule-driving. This is all I can tell you with regard to his antecedents.

The present illness began, as he stated, about a year ago, when he suffered with frontal headaches, which became worse as time went on. He kept at work until last summer, when he fell and injured his head and leg. After this his headaches became worse, and vertigo appeared. His sight also was affected, so that he had to stop work. About two months ago he lost power in his right arm and leg,—not suddenly, but gradually. He also noticed that he could not feel objects touching the left side of his face, and the corresponding side of the tongue lost its power of taste. About the same time he became deaf in the left ear. For two weeks prior to admission he had a ringing in his right ear. For seven weeks he had been under treatment at an eye-hospital, but his sight grew steadily worse. He also had some difficulty in swallowing. His lungs, upon admission, were found to be normal. The splenic dulness was not increased. The urine was alkaline shortly after it was passed; specific gravity 1026; there was no albumen present. The frontal headache is still very severe at times, and strabismus, due to paralysis of the external rectus of the left eye, is observed. The pupils are dilated. He can see more distinctly with the right than with the left eye. There is no ptosis, but the left eye cannot be tightly closed, owing to orbicularis paralysis. The face is drawn slightly to the right, there is still partial anæsthesia of the left side of the face, and he cannot speak very distinctly. Hearing is impaired in both ears, but most decidedly in the left ear. Sensation and motion are still impaired in the right arm and leg, where the tendon reflexes are exaggerated. In the left arm and leg sensation and motion are preserved.

He has less headache this morning than usual, but it is still frontal in character. There is yet a decided difference between the two arms, and his grasp with the right hand is weak. He can kick better with his left than with his right leg, and in walking he barely lifts the right leg from the ground. He can walk with his eyes shut, though hesitatingly: he walks in a straight line. The patellar tendon reflexes are distinct on both sides. He seems intelligent, and takes interest in what is going on around him. His temperature is, and has been, normal: on one occasion only has it attained 99°.

I repeat the observation made on admission,—that there is no heart-lesion. The pulse ranges from 80 to 90. There has been no vomiting. Tongue slightly coated; bowels tend to constipation. He has not been delirious at night. His mind is always as clear as at present, but he has not a very good recollection of dates. It is a steady headache that he complains of; he has had no vertigo since his admission. He is still unable to close the left eye.

Now, gentlemen, I have told you all about this case except the report of ophthalmoscopic examination. The pupils respond to light. There is complete paralysis of the external rectus of the left eye, and paralysis of the orbicularis. The vision of both right and left eyes is impaired. Optic disks are swollen; veins are enlarged. There are striated hemorrhages just above the disk in the left eye. We have, therefore, choked disks, with hemorrhages. [Patient taken out.]

What is the explanation of this group of symptoms? There are only two suppositions that are plausible. This patient has chronic meningitis with thickening, most marked at the base of the brain, principally upon the left side; or he has a brain-tumor. I cannot see how else to explain the phenomena of defective sensation upon left side of face and tongue, deafness in the left ear, with paralysis of muscles of the left eye, together with motor paralysis of the right side of the body. On no other supposition than the presence of an exudation or a tumor could we understand the evident existence of pressure. Let us discuss this question. Is it a tumor, or is it meningitis? In the first place, we have a very obscure history. The boy had violent headaches before he fell and struck the back of his head; on

the other hand, he had no specific history nor anything to give rise to a tumor. Everything is in favor of meningitis caused by a fall, except the history of prolonged attacks of headache before the fall took place. The symptoms presented have more of the character of those caused by meningitis than of those caused by a slowly-growing tumor. But having approached the subject with unbiassed mind, and after going over the facts, I conclude that the boy has a brain-tumor rather than meningitis. Notwithstanding the history and the points which favor meningitis, the evidence is against the view that there is sufficient meningitis to produce these symptoms. In the first place, you have noted the entire absence of fever. My experience with chronic meningitis is that it gives rise to exacerbations of fever; during the day the temperature may be normal, but at times there will occur nocturnal fever associated with delirium. Another point is that in meningitis the superficial portions of the brain, too, become affected, and there is either irritability of temper or impairment of memory; or, in other words, that other cerebral symptoms are apt to be present besides those of headache and paralysis. The boy's memory is good except for dates, and he has a good temper. These are strong points against meningitis. I may add another one, though of less value than those I have mentioned. This boy has had no convulsions. Yet I do not lay much stress upon this, because in brain-tumor you may also have convulsions. You will ask, Does the eye-examination give any light upon the diagnosis? No. The conditions found might be all accounted for by the pressure exerted in either case,—by an exudation as well as by a tumor; though the hemorrhages and signs of intense pressure are more in favor of a tumor as the cause than of meningitis.

Now we shall turn our attention to some points which need discussion in connection with the diagnosis of tumor. Let us ask, Where is it situated? What is its character? With reference to the last question, the nature of the growth is rather obscure. But from its slow course I conclude that it is not cancer, but, probably, one of the forms of non-malignant growths due to increase of areolar tissue. It is not aneurism, because there is no whirr or thrill perceived when the stethoscope is applied over the temporal region. My belief, then, is that it is not cancer and not aneurism, but a connective-tissue, non-malignant growth.

Where is the site of this tumor? It is not always easy to say where the tumor is situated. Sometimes due consideration of the special senses affected, together with our knowledge of the physiology of the cranial nerves, will enable us to decide very positively upon the locality of the lesion; in other cases it may be impossible. In this case I think that I can locate this tumor satisfactorily. Here is a crossed paralysis,—left side of face and right side of body,—and loss of sensation on the left side of face and tongue. This can be produced only by a lesion very low down, but yet above the point of decussation of the motor tracts. The growth must be on the left side of the brain. It must be near the origin of the gustatory nerve, and must also be in a position to press upon the portio mollis of the seventh nerve going to the left ear; the portio dura is also affected, as is seen in the paralysis of the facial muscles. This is clear. For the reasons assigned, the growth must be on the left side of the brain, and at its base, at a point where it would be in contact with the nerves passing from the medulla and pons.

As the hour has expired, I will merely state, in regard to treatment, that the boy has been taking large doses of iodide of potassium, and is doing well on it. I do not know anything better. With this, small doses of bichloride of mercury have been administered (ten grains of iodide and a twenty-fourth of sublimate three times a day). He has now been taking this for ten days. He declares that he feels better, he has less headache, and he walks better. There is now very little impairment in his gait. I have spoken about the advantages of iodide of potassium in the treatment of brain-tumor before, and need not now refer to them again. Shall we continue this treatment, or shall we increase the iodide to twenty grains three times a day? We will gradually increase the remedy to larger doses as long as he improves under it or until the symptoms disappear. This is not done because I have any idea that the boy has syphilis, but because it does good irrespective of syphilis. In addition, he might derive some relief from a blister applied behind the ear. A laxative might be given two or

three times a week, and if the headache prevents sleep he shall have some chloral hydrate at night.

ORIGINAL COMMUNICATIONS.

THE IRRITABLE HEART AND THE DEPRESSED HEART.

BY HENRY SALZER, M.D.,

Baltimore, Maryland.

(Continued from page 407.)

IN the description of the pathological consequences of this condition which is to follow, I trust the justification of this name will be found.

It is hardly necessary to state that many of the patients affected in this manner have never suffered from irritable heart. I have thought it not uninstructive, however, to contrast the symptoms of the two conditions, in order to bring out more clearly their differences.

Physical examination of persons after middle life, especially if they have a tendency to corpulence or are in easy circumstances,—*i.e.*, are not required to perform hard physical labor,—will often show a weak, or quite imperceptible, apex-beat. Life-insurance examiners frequently make this observation, but without attributing any serious meaning to it. If the area of dulness and the heart-sounds are normal, and other evidences of good arterial circulation are present, the asthenic apex-beat and the frequency of pulse are ascribed to nervousness, excessive use of tobacco, or the emotional excitement produced by the examination. The insurance official is probably justified in ignoring this symptom in many cases, for it is, in the early stages, not significant of pathological alterations in the heart or of diminished cardiac power. It has been likewise shown that the strong, sharp apex-beat of irritable heart is not an evidence of increased cardiac power, but a symptom of abnormal innervation. A strong apex-beat may likewise be present in conditions of great structural alteration of the heart, as in the striking case of Mrs. Tate related by Balfour.* This patient was over eighty years of age at the time of her death, and had long suffered from angina pectoris, for the relief of which hypodermic injections of morphine and inhalations of chloroform had been used. "After death, the aorta was found dilated, the orifice of the middle coronary artery—there were three in her heart—almost entirely blocked up by atheromatous deposit, and her heart not only thin-walled and somewhat dilated, but of a pale yellowish tint, soft, and thoroughly fatty; no muscular fibre could be more completely degenerated; yet chloroform produced in her no dangerous symptoms, and, far from shortening her days, seemed certainly to prolong them. I may also add that *her apex-beat was tolerably firm to the last.*"

This case proves that the force of the apex-beat has no relation to degenerative changes in the heart-tissue, and is not significant of such changes.

Several elements combine to produce the cardiac impulse: first, the impact of the apex of the left ventricle, which in contracting forms a hard, conical point, and, by a slight twisting motion during contraction, is thrown to the front and made to strike against the chest-wall; secondly, the recoil of the heart at the moment of the emptying of the ventricles.

The changes of position of the heart during systole and diastole may be compared to a "see-saw" motion. As the apex rises towards the chest-wall during contraction, the twisting movement above referred to causes the lower end of the ventricle to come to the front and impinge with some force against the ribs or intercostal space. If now, without any loss of force in the contraction, the twisting and turning forward of the ventricular apex is changed or diminished in extent, the impact against the chest-wall is diminished or perhaps entirely abolished. It will hence be readily understood how, in young persons with irritable heart but no restriction of the twisting movement or in the normal systole, the abrupt contraction of the ventricle forces the hard point or apex sharply against the anterior wall of the thorax, and produces the strong impulse and concussion which are such noticeable symptoms of an irritable heart. Even in fatty or atrophied heart the normal impulse may be maintained so long as the twisting upon the longitudinal axis of the ventricle takes place during contraction.

In older, fleshy patients, on the other

* Diseases of the Heart and Aorta, p. 285. Philadelphia, 1876.

hand, in whom the symptoms of nervous depression are more prominent, the abrupt, jerky contraction of the ventricles has given place to a more regular systole. In consequence of the overfilling of the venous system, to be presently described, the right ventricle is more encumbered by the mass of blood, and the twisting movement by which the left ventricle is brought to the front during systole is incompletely executed, and the apex does not strike the chest-wall with the normal impact. The slight concussion of the chest which may be felt is merely an expression of the cardiac movement as a whole. Although this symptom is also recognized as one of excentric hypertrophy of the right ventricle, there is no dilatation present in the cases above described. The right ventricle is merely filled beyond its average capacity, while the left is only normally, or less than normally, filled. Inasmuch as there are no actual changes of size and form in the heart as yet, the area of cardiac dulness and the point at which the apex-beat may be felt on deep inspiration and stooping posture remain normal. This normal place of the cardiac apex-impact is in the fourth or fifth intercostal space (oftener in the latter), about two inches to the left of the left lateral margin of the sternum. The heart-sounds are normal, with the exception of a sharp accentuation of the second pulmonary sound, which is due to the increased labor of the right ventricle.

We owe to Oertel the explanation of the turgidity of the venous system found in these patients. I am of the opinion, however, that this acute observer attributes too much importance to fatty heart, and assumes its existence in too many cases, while entirely overlooking the absence or weakness of the apex-beat in relation to the condition under consideration.

While acknowledging and valuing the labors of such masters as Da Costa and Oertel in this field, the careful and observant family-physician, with his opportunities of following the careers of his patients through a lifetime, may note facts or arrive at conclusions which, from their brief period of observation, are not available to the hospital physician or the consultant.

Professional persons, or such as are in easy circumstances, consume, as a rule, a quantity of liquid and solid food which would more than suffice for the nutrition of a stevedore or hod-carrier. The venous system of the abdomen is admirably adapted to act as a temporary receiver for the excess added to the blood by absorption from the intestinal canal. The abdominal veins are capable of taking up a quantity of blood equivalent to the average mass of the entire blood-supply of the body.

These veins, including both those of the portal and general abdominal circulation, together with the chyle and lymph-vessels, take up all absorbable, especially the liquid, portions of the food from the intestinal canal, and convey them into the right auricle, and thence into the right ventricle. If the heart is healthy, it soon disposes of the larger amount of blood passing through it by more rapid contraction. Inasmuch as both ventricles contract synchronously, it happens that the left ventricle is less completely filled at each contraction than the right. The arteries, in consequence, are distended, the pressure in them decreases, and a diminution in force and increase in frequency of the pulse result,—the former owing to the lessened blood-pressure, and the latter owing to the more frequent cardiac contraction.

But our fleshy patients may still maintain their health, because the excess of liquid taken in increases the activity of the skin and kidneys. If sufficient bodily exercise is taken, the rapid and energetic muscular contractions support the turgid veins and lymphatics, and aid in restoring the normal circulation. To accomplish this, regular and moderate bodily exercise is beneficial, while spasmodic or violent exertions, with long periods of rest, are vicious. Moreover, if to the overfilling of the veins and right side of the heart above mentioned be added the customary prescribing of large quantities of mineral waters and liquid diet, for the purpose of increasing the intestinal and renal secretions, the morbid condition will become more sharply defined.

The patient perhaps still takes active exercise occasionally, he perspires freely, his kidneys act fairly well; he is still healthy so far as a physical examination can determine, with the possible exception of slight catarrhs, neurasthenic symptoms, urine of high specific gravity but not containing albumen or sugar: in short, he presents the collection of symptoms above described as belonging to a case of depressed heart; although the insurance offi-

cial, basing his opinion upon the physical examination alone, and not looking into the future, would still be justified in accepting the individual as a good risk.

Should a favorable change now take place in the condition and mode of life of the patient; if he engage in more active exercise, stimulate the functions of the skin by means of baths and frictions, reduce the amount of food and drink consumed, and if the food be more thoroughly masticated and digested, then the abdominal veins will be less distended, the general vascular system better supported in moving the blood-current, the arteries better filled, and the entire circulation equalized. As in the other case all the circumstances combined to characterize more sharply the clinical picture of the depressed heart, so in this all these abnormal conditions gradually pass away, and after months, or possibly years (for improvement goes on slowly), the health may be perfectly re-established, thus justifying the favorable opinion of the insurance examiner to which we referred.

But should the consumption of solid food and liquids, even though the latter consist only of water or other indifferent liquids, continue, or if the amount of drink be increased in consequence of habit, thirst, or even medical advice, then the renal excretions decrease on account of venous congestion, the functions of the skin diminish through lack of exercise, baths, and frictions, the return of the blood from the lower portions of the body becomes impeded owing to deficient muscular contraction, and the heart, already predisposed to relaxation, is subjected to additional strain. The engorgement of the pulmonary circulation embarrasses the respiration, and thus diminishes the metabolic activity in the lungs and tissues. As a consequence, the products of suboxidation — uric and oxalic acid, urates and oxalates—are produced in excess, instead of urea.

The proposition of Weber—that the pulsation of the heart is not transmitted to the veins—loses its force here. The arteries, stimulated to excessive contraction in order to overcome the high blood-pressure in the capillaries and veins, begin to manifest the results in endarteritis and analogous pathological processes. The continued engorgement of the right ventricle leads to dilatation and compensatory hypertrophy of the right heart, which is followed by similar changes in the left heart. The hypertrophy of the left ventricle easily becomes greater on account of its greater muscularity, and because the already diseased arterial walls furnish an additional obstruction to overcome. The prolonged engorgement of the kidneys, acting upon the nervous supply of these organs, gives rise to increased secretion, and arterio-capillary fibrosis is established. The constant turgescence of the hepatic veins, together with the irritation of the parenchyma of the liver by spirituous drinks, may lead to excessive diapedesis of the accumulated leucocytes in the dilated veins and new formation of connective tissue, ending in cirrhosis; or the endarteritis produces miliary aneurisms or apoplectiform extravasations of various sizes, or scleroses in brain and spinal cord.

When these conditions are fairly established, the symptoms of depressed heart give way to the manifestations of organic disease, such as chronic gout, gravel, cirrhosis, Bright's disease, sclerosis, etc. When the morbid condition has progressed to this stage, restriction of food and drink and medicinal therapeutics may arrest it, but can no longer cure. The insurance examiner who passed the individual made a grave mistake in overlooking the symptoms of depressed heart and ignoring their possible consequences.

According to my experience, the favorable ending first described above is exceptional, unless the individual changes his mode of life. Now, inasmuch as the insurance examiner would be exceeding his privileges if he attempted to act as medical adviser to the applicant, the former should, in the interest of the company, be exceedingly cautious in accepting as good risks persons with weak or imperceptible apex-beat combined with the other phenomena of depressed heart. He should, at least, take into consideration the applicant's occupation and mode of life.

The current opinion that corpulence alone will cause weakened cardiac impulse is not confirmed by my experience and observation. If the cardiac innervation be normal, and the heart neither engorged nor underfilled, so that the twisting of the left ventricle takes place to the front during the systole, the apex-beat will be distinctly perceptible, even if a considerable thickness of adipose tissue interposes between the heart and the examining finger.

A few points in regard to the therapeutics of this condition may be here added. Each case must be thoroughly studied, and treated according to the special indications. Restriction of fluid and increase of solid food cannot be ordered indiscriminately, because the excessive consumption of liquids is not the sole cause in all cases. A very corpulent female patient whom I had under treatment for depressed heart illustrates this very well. The quantity of fluid ingested daily did not exceed two pints; the patient ate comparatively little, and was kept pretty actively employed during the day by her household duties. The only abnormality in her dietary that could be discovered was that the liquid consumed consisted of very strong coffee and that she ate much confectionery between meals. The medicinal treatment consisted of a placebo, but the sweetmeats were strictly forbidden and the strong coffee substituted by weak tea or *café au lait.* The morbid phenomena have after a few months' treatment entirely disappeared, and the apex-beat is again becoming distinctly perceptible. As a rule, corpulent persons are habitually thirsty and liable to overload the venous system by yielding to the demand for fluids. Hence the first therapeutic indication is to endeavor to equalize the ingested and the excreted liquid. If a true gastric catarrh exists in combination with the other symptoms, it will often be necessary to order a fluid or semi-fluid diet, but it will be of prime importance in these cases to stimulate the excretory organs. Baths, frictions, exercise in the open air, gymnastics, massage, or faradization will be indicated in addition to supervision of the dietary. The fluids ingested should be such as will act as stimulants to the secretory functions of the skin and kidneys, but it will be better, on the whole, to reduce the quantity of liquids taken than to consume them in excess and afterwards remove them from the body by evacuants (laxatives, diaphoretics, etc.). A proper reduction of the amount consumed will diminish the mass of venous blood, while active exercise in the open air, especially moderate mountain-climbing, will promote the arterialization of the blood. The food should be easily digestible, and should exclude such articles as are prone to form injurious compounds in the body,—for example, tomatoes, which are so rich in oxalates.

According to Flint, the average quantity of fluid consumed is from fifty to sixty ounces. This should be sufficient for an active working-man in summer. In winter, for one less actively employed, half of this should suffice for all demands of the economy. The physician must exercise common sense in regulating the quantity of fluids consumed in accordance with the patient's condition and mode of life. Hard and fast rules are not applicable here.

When the above indications are correctly appreciated and consistently carried out, the results obtained are often very surprising and gratifying. After a month or two of the treatment, the quantity of urine increases relatively to the amount of liquid drunk and the specific gravity approaches more nearly to the normal figure, the uric acid diminishes, the moist eczemas disappear without special treatment, the joints lose their stiffness, the muscular movements become more elastic, the sexual desires and powers return, and after from four to six months a decided improvement in the force of the apex-beat is noticeable.

The objection may be raised that many persons eat much and drink still more, and yet retain their health. But these persons are endowed by nature with a resistant organization which enables the circulatory and excretory organs to withstand the evil effects of temporary strain. Their mode of life is such as to preserve a proper relation between consumption of food and excretion of excess of fluid and the products of metabolic activity. *When, however, these individuals change their habits, and, instead of taking a reasonable amount of bodily exercise, sit and drink by the hour, no matter whether the drink be wine, beer, cider, or water* (*stronger liquors are, of course, out of consideration altogether*), *without a corresponding increase in the renal secretion, they are soon driven to consult a physician for the relief of the symptoms of depressed heart.*

Another point may be here referred to. There certainly are persons who, in spite of great moderation in eating and drinking, become very corpulent, although according to my experience they are rare exceptions. In these cases I have always found an apex-beat of normal force, or, at all events, strong enough to be distinctly felt. Where the latter was imperceptible, some

other disturbance of the circulation could easily be discovered on careful investigation.

It is not asserted that a distinctly perceptible apex-beat is to be considered as a certain indication of a healthy heart. Slight displacements of the heart due to previous changes in the thorax may cause the apex-beat to be felt in the normal situation, although the heart may show distinct disease. The case above quoted from Balfour is also in point.

I have endeavored to point out in this paper the importance of attributing a weak or imperceptible cardiac impulse, when joined to the other symptoms mentioned, to a depressed heart. It is extremely important to the patient that this condition shall be early recognized, and its causes sought out and removed before the beginning of organic changes. The causes will generally be found either in the consumption of too much food (fluid or solid), lack of exercise, lack of attention to the skin, too little fresh air, indigestion from deficient mastication, too rapid eating, improper or irritating diet, mental and physical overwork, abuse of the natural powers, excessive use of coffee, tea, or tobacco, or in a number of these combined. The removal of these causes is the first indication in treatment. The use of medicines is secondary.

In conclusion, it may be stated that exact sphygmographic and cardiographic observations, as well as correct time-measurements of single heart-contractions both in the irritable and in the depressed heart, are beyond the range of possibility to a family physician. Competent hands should take up this work, and by exact scientific observations check the clinical experiences which I have here set down.

REPORT ON THE PROGRESS OF OTOLOGY.

BY CHARLES H. BURNETT, A.M., M.D.,

Professor of Otology, Philadelphia Polyclinic, etc.

(Continued from page 409.)

CARIES OF THE MASTOID.

W. KIRCHNER (*Würzburger physicalisch. med. Gesellschaft*, and *Archiv f. Ohrenheilk.*, Bd. xxiv. p. 61, 1886), in examining the ear of a young man who was in a surgical clinic on account of gangrene of the muscles of the neck, found an extensive carious destruction of the mastoid portion which had been caused by the gangrene. A post-mortem examination revealed that the mastoid portion was nearly entirely destroyed, the sinus transversus exposed for a space of three centimetres, and also that a large destruction had occurred in the external auditory canal. The membrana tympani was nevertheless intact, and the tympanic cavity contained but little pus and its mucous membrane was but little thickened.

RUPTURE OF THE INTERNAL CAROTID ARTERY SUBSEQUENT TO NECROSIS OF THE TEMPORAL BONE.

Dr. T. Y. Sutphen, of Newark, New Jersey, gives an account of a fatal result from the above-named causes (*Archives of Otology*, vol. xv. No. 4, 1886). The patient was a man 25 years old. When a child he received a blow upon his right ear, which, resulting in a discharge, continued with varying intensity until the time of his coming under recent observation. An abscess beneath the ear had formed some years previous, and, forming again, he had sought relief. Examination revealed a swollen condition of the auditory canal, a tympanic cavity blocked with granulations, and the probe revealed the presence of denuded bone. The abscess beneath the ear was shown to communicate with the tympanic cavity. In the course of five months from this observation by Dr. Sutphen, the patient was again seen as an inmate of the hospital, when it was ascertained that facial paralysis on the right side had made its appearance about three weeks previous, and that within three days the left side of the body had become paralyzed. Severe pain in the right side of the head, dizziness, and nausea were complained of. The patient would not permit any operation for the removal of dead bone. Under tonics and hot fomentations to the ear the patient recovered the use of the paralyzed side, and in three weeks left the hospital. The facial paralysis and the otorrhœa remained.

In the course of a month after his departure from the hospital, the patient returned to the clinic, reporting an exacerbation of headache and vomiting. Bromides were given, and fomentations applied over the affected ear. In the course

of ten days there was a profuse hemorrhage from the ear, followed by cessation of pain and an increase in the purulent discharge. Numerous hemorrhages occurred in the course of the subsequent five days, and finally he became very weak and pale from loss of blood. Patient sank in five days, death being preceded by intense pain in the back of the head and down the neck to the shoulder on the right side, accompanied by some delirium.

The post-mortem examination revealed the following: "The temporal bone in the region of the middle ear had been changed into one large carious cavity, containing a sequestrum irregularly oblong in shape, one inch in length, and about seven lines in breadth and thickness." There was necrosis of the internal auditory canal, involving the auditory nerve. On removing the sequestrum, an opening was found in the carotid artery, the walls of which were softened. Opposite the internal meatus there was an abscess-cavity in the cerebellum, containing a drachm of dark, thin pus. "Adjacent to this, above and anteriorly, was a mass of cicatricial tissue, occupying the entire thickness of the gray matter, cut with difficulty, and presenting a discolored, uneven surface, probably the result of an abscess which had healed. The fourth ventricle contained an ounce or more of dark serum. On the superior surface of the cerebellum was a large discoloration, showing evidences of a former localized meningitis. The brain in all other respects was healthy."

It is maintained by the writer that there was no hope of relief in any operation in this case.

PISTOL-SHOT WOUND OF THE RIGHT MASTOID PROCESS.

Dr. Gorham Bacon, of New York City, gives an account of this rare accident, occurring in a woman 23 years old (Transactions of the American Otological Society, July 20, 1886). The wound occurred by the accidental discharge of a pistol six feet from the patient. The ball struck her just behind the ear and entered the mastoid process, being embedded in the cellules near the antrum. Four months after the accident the patient was etherized, and a sequestrum, which had found its way into the right auditory canal, was removed. An opening was made from the auditory canal into the mastoid cells, and pieces of the bullet were removed; but, this opening not being large enough, the mastoid cortex was trephined. Some pieces of bone were removed through this opening in the mastoid, and the bullet was distinctly seen lying against the mastoid antrum. The operation was now interfered with by symptoms of collapse on the part of the patient.

In the course of two days the patient was again seen, and some traction made upon the bullet, but, as this caused pain and the patient would not be again etherized, all further attempts at removal of the bullet were stopped.

After treatment of the case as an outpatient for two weeks, it was observed that the mastoid wound was healing, the bullet remaining in the mastoid. The patient soon disappeared entirely from the clinic, and all trace of her was lost.

WOUND OF BOTH EARS BY PISTOL-SHOTS.

M. Rollin, interne of the Hôpital Bichat, gives an account of gunshot-wounds of both ears, occurring in the service of M. Terrier, as the result of an attempt at suicide in an insane man, 27 years old (*Annales des Maladies de l'Oreille*, December, 1886).

At the time of his admission to the hospital there was considerable hemorrhage from both ears. The patient was semi-comatose. Without any examination, both ears were plugged with iodoform gauze. The next day the temperature of the patient rose to 39° C. (102° F.), but in the course of a week fell to 37° C. (98° F.), and the patient became less dull. It was then found that deafness was absolute on both sides. There were soon observed symptoms of facial paralysis on the left side, which increased and became complete in the next few days, comprising the orbicularis palpebrarum, and demonstrating a lesion of the facial within the petrous pyramid. The cheek became flabby, the eye remained open during sleep, and mastication became difficult. In a month from his admission, an abscess formed above the right masseter muscle, in front of the auditory canal. The incision liberated a large quantity of thick, reddish pus. In the course of a few days, after the abscess had healed, a probe introduced into the right ear encountered a metallic substance two and a half centimetres from the opening of the canal.

Six weeks after the wound, the mental condition of the patient was a little better; the deafness, however, remained absolute, and trophic changes had begun in the left eye, on the paralyzed side. The eye became red and painful. His mental condition now grew very much worse, and, although continuing so, M. Terrier decided to undertake the extraction of the balls. The operation was performed somewhat over two months after the accident.

An incision was made, following the posterior auricular groove, and the auricle was loosened and drawn forward. The auditory canal was then cleared out and "scraped with a gouge, not without difficulty." The ball was then extracted, very much misshapen. Catgut sutures were then inserted, drainage of the auditory canal maintained, and the parts dressed with iodoform and carbolic acid. In a few days the wound healed. The general condition of the patient, however, became worse: he grew thinner, and the cornea of the left eye became uniformly opaque. He then became better in the course of a month, and remained so for a time, when suddenly his insanity grew worse. In about six weeks after the first operation it was decided to endeavor to extract the ball from the other side. The ball was found here at a depth of five centimetres.

The procedures were the same to reach the position of the bullet, though the hemorrhage was greater, in consequence of the deeper incisions necessitated by the depth of the ball. Some pieces were extracted, but when forcible traction was made upon the bullet a copious gush of bright red blood put an end to further interference, as it was supposed the hemorrhage came from the wounded internal carotid. Before resorting to ligation of the primitive carotid, M. Terrier made a firm tampon of iodoform gauze in the external auditory canal. After this the mental condition of the patient improved considerably, but this was only of short duration, and the case was placed in an asylum for the insane.

The left eye finally sloughed out; from the left ear a slight discharge still issued, and a probe encountered, at a depth of four centimetres, denuded bone and granulations.

The right ear healed entirely. The deafness on both sides remained absolute.

THE GYMNASIUM AS AN AID TO THE PHYSICIAN.

BY CHARLES McINTIRE, JR., A.M., M.D.,

Lecturer on Hygiene and Medical Director of the Gymnasium, Lafayette College.

I HAVE no doubt that many of the readers of the *Times*, as they read the caption of this article, will recall *Punch's* suggestion that every foot-ball match be attended by an ambulance and a staff of surgeons, and will think of the possible fractures and more probable bruises. That would be of very material aid should they occur in one's practice. But these words are not used to convey such pleasantry. Indeed, definitely-prescribed exercise is the thought that is to be considered, whether it be had in or out of a gymnasium.

Experience is rapidly demonstrating—if it has not already done so—that there are many poorly-shaped, unequally-developed, and under-normal men (possibly women, too), besides others in whom there is not a proper harmony between blood and nerve, or brain and brawn; and that these people are continually breaking down, or using up, or are threatening to; and that the maladies expressing their condition are more difficult to cure because of this lack of harmony, or of some well-marked departure from a normal organism. There is a difficulty to secure the proper quality of blood, or to prevent excessive wear and tear,—not from any want of skill on the part of the physician, but from the condition of the patient himself. It is in this class of cases that the gymnasium frequently gives valuable assistance; in many cases as a prophylactic, in others directly as a curative agent. But when we speak of a gymnasium our minds must not at once picture double-trapeze acts, tumblings, and other feats of the circus-ring. These are unnecessary, often forbidden. We must think of the lighter instruments,—the pulley-weight of various kinds, and other apparatus adapted to the weakest, and capable of being used to exercise certain muscles and produce definite results. A man is blue from an attack of indigestion: "Fling but a stone, the giant dies," says Sterne; but hardly with truth. The stone may hurt him, but hardly despatch him. Slings as instruments of warfare are obsolete, and it is necessary to use something adapted to

modern habits. Let us plan and execute some means of exercise that will strengthen the abdominal muscles,—not neglecting other things, of course. We will thereby change the condition so that instead of feeling a soft, non-resistant, springless mass when the abdomen is touched, we will find firm muscular walls whose very touch is elastic and betokens strength; and in so doing you will, in many a case, change the condition of the parts under the abdominal walls, and a decided eupepsia will have supplanted the former condition of dyspepsia.

In the use of gymnastic appliances it is necessary to study each case for itself. The gymnasium provides neither a panacea nor a specific; and there are many forms of exercise which, comparable to the old saw, "One man's food is another's poison," are often harmful to an individual, and should by all means be forbidden. Usually, however, our patients' sin in relation to exercise is one of omission, and not of commission: so that our duty more frequently is positively to direct the exercise to be taken, rather than forbid the use of any form of exercise. Thanks, however, to the workers in this field of study, we have learned that exercise is complex in character, and, when prescribed as a therapeutic measure, should be selected with as much care as is any drug. The use of a certain set of muscles alone will deform a well-built man; the use of that same set may be necessary to bring into harmony an unsymmetrical one. The point that it is desired to emphasize is, that telling a patient to take exercise, or a definite amount of exercise, is not enough, but we must prescribe its character as well; and, as in all remedial methods, we must be careful to have a very clear view of the end to be accomplished before we prescribe. The man who gives a prescription simply because it is said "to be good for" some disease will probably not find much good result from adding muscular movements to his list of remedies; but that one who studies out his cases and sees that it is desirable to obtain a definite result, which he thinks can be brought about by a certain line of treatment, will frequently find that definitely-prescribed exercise will be a great help. The use of Dyer's method of exercise in asthenopia will illustrate this, although it would not ordinarily be classed among gymnastic performances.

In our thoughts about exercise we must remember that the muscles are not alone acted upon, but the blood-vessels, nerves, and other tissues as well; and frequently we have here a valuable aid, enabling us to secure otherwise impossible results.

It might be inquired why such positive assurances are made of the excellent results to be obtained from the systematic use of exercise. The reasons are plain. There is, first, this departure from a normal standard of the individual, alluded to earlier in this article. Any one will accept the statement that there is a relation between the size, *e.g.*, of the lungs and the height of an individual which will permit the highest degree of health; and then it follows that any departure from this relation by so much prohibits the highest degree of health,—by a very small quantity, perhaps, but still by some quantity. Now, if in an individual this relation does not exist, and by your exercise you make the relation more nearly the normal one, you strengthen the individual; and what is said of the relation of lungs to height is also true of all the proportions of the body.

If any one desires to study this idea of a normal standard further, I would refer him to the writings of Dr. Nathan Allen, of Lowell, Massachusetts, who has very carefully and thoroughly presented many phases of the subject.

Selected exercise, then, brings man nearer his normal proportion. Then, again, there is comparatively little of this kind of exercise given; so that we have fallow ground to work upon, which will very probably yield us large and favorable results. The proof that too little developing exercise is taken lies in the fact that so many people are poorly developed. A fine-looking, well-developed man is a matter of observation and remark on our streets. And from the results obtained whenever developing exercise has been employed upon persons as ordinarily seen, it is fair to conclude that if such exercise were used to any great extent there would be more individuals seen who were well developed.

Of course, much of this aid to our profession will be in the line of preventive medicine,—probably the highest form to practise. By building up the proportion of strength and functions of the body to a normal, there will not only be fewer attacks of disease, but many forms of disease will be better resisted.

A statement made by Dr. Morgan in his "University Oars" is wellnigh worn threadbare by oft quotation, but so apt is it here that I venture to use it. In speaking of increasing the size of the chest, and thereby of the lung-capacity, if in an attack of pneumonia, "these additional fifty inches will amply suffice to turn the scale on the side of recovery. It assists a patient successfully to tide over the critical stage of his disease."

This exercise for development can be secured by free movements alone,—*i.e.*, without any apparatus whatever; although some allege there must be some weight moved in order to cause exercise to avail for development. Without discussing this, it is certain that free movements can produce fatigue. One may, however, use dumb-bells or wands: a cane will do. Some one of the numerous forms of pulley-weights—any of these can be made useful; some are more convenient than others—will form one of the best means of procuring definite exercise, on account of the ease of directing the character of the movements. An expenditure of from five to six dollars or more will enable any one to set up an apparatus for muscle-development in their own home. The price of a dozen bottles of "Syrup of the Hypophosphites" or "Peptogenitic Elixirs," under any of their numerous aliases, will amply pay for one, be much more agreeable to take, and prove in most cases fully as efficacious, to say nothing of the greater value of the apparatus when compared with the empty bottles. Of course, when it is possible, it is better to send our patient to a gymnasium, where there are trained instructors and a variety of apparatus. We do not hesitate to consult the ophthalmologist or the neurologist: why should we hesitate to confer with the physician in charge of the properly-conducted gymnasium?

My experience during the three years since the opening of the gymnasium of Lafayette College, in the line of consultation and correspondence with various physicians concerning students who are or have been their patients, in order to arrive at a proper prescription for exercise, convinces me that a very respectable proportion of the profession are neglecting to inform themselves of a very important aid in combating disease; and because of this conviction, and in the hope that it will cause some at least to give the subject the attention it deserves, this article was written.

EASTON, PA.

TRANSLATIONS.

ON THE PHOTOGENIC FUNCTION OF PODURIDES.—At a recent meeting of the Biological Society, M. Dubois communicated the following note on the photogenic function of podurides. The faculty of producing light, says the author, is more generally distributed among terrestrial animals than is generally supposed. Every one is now acquainted with the photogenic power of Lampyrides and Elaterides; it has also been detected in Myriapodes, but only by a few observers. On the contrary, there exists but one observation of this kind relative to Podurides, which is due to Professor Allman, and was published in 1850. That savant was the first to observe luminosity in the individuals of the species *Anurophorus fimetareus* (*Leptura fimetarea*, Linn.), in the month of February, on Howth Hill, near Dublin. They were profusely distributed in this place, and the thick piles of dung which were to be found here in great numbers were the only places where they were not to be seen.

Last October the author likewise found luminous podurides in precisely the same locality and at the same time in which he discovered the phosphorescent myriapodes which formed the subject of a preceding communication: that is to say, in the environs of Heidelberg, near the village of Handschuhsheim. In stirring up the humus in a hop-field, the author was surprised to find the soil covered with very little luminous stars, brilliant enough to be distinctly seen at a distance of about forty centimetres on a dark night (it was about nine o'clock in the evening). These little lights were so numerous in places that one might have easily imagined one's self on a beach whose sand was filled with noctiluces. An examination of a portion of the earth with an ordinary lens showed the presence of a small white insect, about three millimetres in length. Having selected a few individuals among the number and put them in a watch-glass, the author discovered that they possessed the faculty of emitting light, and that they

retained this faculty till death. Although the author was enabled to observe them during several consecutive days, he failed to discover the least sign of the localization of a luminous centre; the whole body of the insect appeared luminous.

Mechanical excitement, heat, and the agitation of the animal visibly augmented its photogenic power. In a general way, they offered the same physiological reactions as the other luminous beings previously observed. The light emitted was bluish, like that of the stars; but, for the want of an instrument, a spectroscopic examination could not be made. On crushing the insects upon a piece of litmus paper, it was plainly seen that the contents of the body were abundantly provided with luminous substance, which gave a manifest acid reaction. This point is important to note, because it establishes a fresh analogy between the luminous substance of pyrophores and of lampyrides; and, on the other hand, it constitutes an objection which no longer permits the acceptance of M. Radzizewski's theory, since the photogenic reactions obtained by that chemist *in vitro* are produced only in an alkaline medium. The luminosity remained for several minutes on the paper where the insect had been crushed, even when wetted with a slightly acid liquid; while ammoniac vapor caused it to disappear immediately. When some of the crushed substance was placed upon the tongue, a manifest sensation of acidity was felt, together with a taste recalling that of certain mushrooms; the odor was similar to that of rotten wood and of the vegetable detritus wherein they lived.

These insects belong to the group of Podurides, and, although they resemble in some respects the *Lipura ambulans* of Lubbock and Tullberg, they should rather be regarded as belonging to the species *Lipura armata* (Tullb.), on account of the three ocellated points at the base of the antennæ. This peculiarity was observed by M. Gazagnaire in the entomological laboratory of the museum, while the author was only able to find two post-antennal oculated points upon very similar individuals found in Paris, and which M. Gazagnaire considers as representing the species *Lipura ambulans* (Tullb.). In spite of the great similarity between the *Lipura ambulans* and the *Lipura armata*, the author was unable to discover the least trace of luminosity in the latter species; but he does not consider the test as final, as he only observed them at the end of November.

A striking peculiarity in these insects is the fact that their bodies are filled with irregular lobes having great refracting power; and in polarized light, when the Nicol prisms are crossed, these lobes show that peculiar aspect which is observed in the luminous organs of pyrophores and lampyrides, and which is found in the digestive tube of luminous myriapodes. These lobes form, on the surface and on the sides of each ring, salient points, which have been taken for stigmata. Lubbock, on the contrary, considered them as adipose tissue. This also is the author's theory regarding them, in spite of the authority of Tullberg, who looked upon them as *systems of urinary canals*, "which seem to resemble the ramified glands of Malpighi in certain acari, but which differ from them in not having canals with an opening."

To these singular urinary canals without an opening Tullberg found an enveloping membrane, composed of two layers, one external, orchist, and the other internal, cellular, and precisely in this same *Lipura armata* which presented the phenomenon of luminosity. The author endeavored in vain, by means both of section and of dissociation, to discover this enveling membrane composed of two layers; and, moreover, it was easy to see, by a simple examination of the preparations and by the figure given by Tullberg, that these parts, as well as the lobes, should be considered as adipose tissue. These lobes are composed of cells of the same nature; but those which are situated in the centre of the lobes are filled with rounded granulations, which Tullberg erroneously considers as urinary concretions. These granulations are not agglomerated in a canal, but in cells having an irregular contour, without an apparent membrane, and sometimes connected with one another by connective-tissue prolongation. These granulations and the cells which contain them are thoroughly comparable to those which are found in the luminous organs of pyrophores and of lampyrides, and the cellular wall of the pretended urinary canal is constituted by cells which as yet have no rounded granulations, and the nuclei may easily be distinguished after coloration.

Also, great importance should not be given to the presence of uric acid, which, according to Tullberg, had been observed by Professor Allman, because it is well known that almost all the parts of insects contain more or less of it. These granulations present peculiarities that are extremely curious. They have generally been considered as particles of urate of ammonia animated with Brownian movements. The author formerly considered them as unorganized particles containing guanine or a very similar substance; but more recent observations have caused him to change his opinion, and this will be the subject of a future communication.

Influence of Solar Rays upon Microbes.—At another meeting of the same society, M. Straus made a communication respecting the action of luminous rays upon microbes. M. Arloing has stated that the spores of the bacillus anthracis, placed in cultivations of broth and exposed to the sun, are destroyed; whereas vegetating mycelium resists a much longer exposure to the solar rays.

This fact is interesting if the resistance of these spores to all influences is borne in mind. MM. Nocard and Duclaux advanced the hypothesis that the solar rays acted much more upon the cultivation than upon the spores. M. Straus has confirmed this hypothesis in the following manner. The spores, placed in pure distilled water, resisted the action of the solar rays to which they were exposed for four hours; placed in broth, they were destroyed at the end of two hours.

M. Duclaux stated that he had observed, in some similar experiments he had made, that the period of two hours, which is sufficient to destroy young spores, is not sufficient to destroy spores two or three years old. M. Straus stated that his experiments were made with spores two or three months old. M. Duclaux's experiments were made with much older spores.

M. Chaveau added that spores of the bacillus anthracis when two or three months old can be considered young.

The Treatment of Phthisis by Inhalations and Injections of Carbonic Acid Gas.—Dr. Dupont, in a communication to the *Bulletin Général de Thérapeutique*, calls attention to the fact that Priestley first recommended the use of fixed air by injection into the rectum as an "antiputrid agent." This method, however, is unpleasant, troublesome, and less rational than inhalation by the mouth, which possesses all the advantages with none of the drawbacks of gaseous lavements.

The advantages of this mode of treatment are (1) that carbonic acid is antiseptic, and is useful in overcoming the tubercular septicæmia; (2) it is anæsthetic, and quiets the cough; (3) it is a supplemental food, reducing oxidation and lowering temperature; and (4) it stimulates the digestive organs.

Helenine in Diphtheria.—Helenine, obtained from the root of the elecampane, is a concrete, volatile, fatty substance, in white crystals of an aromatic odor and a bitter taste. It is insoluble in water, but soluble in alcohol and ether. Dr. Juan B. Obiol (*La Crónica Médica*), on account of the well-known antiseptic properties of helenine, has tried it in diphtheria. He applied powdered camphor to the patches of false membrane, and dressed with a solution of helenine in oil of sweet almonds. This treatment is aided by the administration of helenine internally in doses of a grain and a half for six-year-old children, being careful to avoid causing vomiting. The dressings must be made daily by the physician, and, when the disease is treated from the first appearance, twenty-four hours is generally sufficient to bring about a cure. At the end of five or six days of invasion, it will be necessary to continue the treatment for eight or nine days. Five or six days later the treatment ceases to be useful. Albuminuria does not occur: constipation is the rule.—*Nouveaux Remèdes.*

The Care of the Subscapular Nerves in removing Enlarged Glands from the Axilla.—Professor Kuster directs attention to the fact that, in cleaning out the axilla after extirpating a cancerous breast, great care should be taken not to injure the subscapular nerves supplying the subscapular muscle, the teres major, and the latissimus dorsi. He had seen cases where these nerves were injured, in which the movements of the arm were so restricted that the patient was unable to fasten her clothing. Since he has paid proper attention to the protection of these nerves he had not seen such results following the operation. — *Centralblatt für Chirurgie*, No. 11.

EDITORIAL.

THE PERSONAL EQUATION IN THERAPEUTICS.

THE temptation to become oracular upon the basis of one's personal experience has been an ever-present one to practitioners of medicine. The Scotch Professor of Anatomy who always referred to his personal peculiarities in order more forcibly to impress his lessons upon the attention of the students is by no means an isolated instance of this kind. The story is somewhat broad, but is happily characteristic of the type of medical man who sets up his own stomach and its propensities as the infallible guide to be followed in directing the dietary of his patients. A typical example of this kind, which might be termed the *argumentum e ventriculo suo,* is just now on its rounds in the medical press, to the effect that "Dr. —— gives notes of a personal experience of nine weeks' illness from typhoid fever, during which he experienced a distinct aversion for food. He argues that this disinclination for food should be respected, and that nourishment should be given to fever-patients only when they call for it."

This opinion is attributed to an eminent Western surgeon and practitioner. While this may be regarded as correct doctrine in his own individual case, we decidedly dissent from the deduction that the experience is a proper guide for other physicians in all cases. One swallow does not make a summer; neither is experience in one case a sufficient warrant for establishing a general rule which shall apply to every patient suffering with a certain form of disease. Since the day of Graves, the systematic feeding of fevers (often forced feeding) has become a general practice, and, when intelligently followed out, has yielded most beneficial results. It was, in our estimation, one of the greatest merits of the late Professor Flint that he so strongly insisted in his writings upon the necessity of supplying proper and sufficient food in all cases of acute disease, without regard to the desires of the patient.

But the proposition which we would especially contest is that any one individual's stomach is a guide for all others. We know a physician who forbids apples, pears, and grapes to all his patients, even when convalescent, because, forsooth, he cannot eat them himself without hypogastric discomfort. Another thinks that eggs in any form must be injurious to the sick because he cannot digest them when well. Still another banishes milk from the dietary of his fever-patients, and would keep them alive on the only spoliative dietetic article known,—namely, beef-tea. In no other way perhaps is the influence of the personal equation shown more directly than in the various recommendations to patients with regard to the use of tea or coffee and alcoholic liquors.

Physicians frequently meet digestive idiosyncrasies in their practice. In fact, their existence long ago attracted popular attention, and became emphasized in the popular proverb, "What's one man's meat is another man's poison." These cases are not sufficient, however, to prevent the establishment of general rules of dietetics. Even the popular proverb quoted is erroneous when generally applied, for it is a fact that what is good for one is good for all as a general rule, to which, however, we must be prepared to find exceptions. Such a rule, in order to have practical value, should be established by a large series of experiences, and the verdict of the individual stomach, whether it belong to peer or to professor, should be rejected as a criterion in dietetics.

The problem of the digestibility of any article of food in any given case is to be decided by the capacity of the patient's stomach, and not by that of the physician, however authoritative or imperious its dictates in forming his own personal equation.

THE TYRANNY OF THE SCHOOL.

THE leading position in the April number of the *Popular Science Monthly* is given to an address delivered by Dr. William A. Hammond before the Nineteenth Century Club of New York, on "Brain-Forcing in Childhood." Dr. Hammond points out the great injury done by the cramming process to the undeveloped brains of young children, and then shows the absurdity of many of the studies with which school-children, especially girls, are burdened. He animadverts upon the mistake of giving children too many subjects to study at the same time, and illustrates the point by referring to the bad effects of "cramming" as indulged in by medical students. He says, "I speak from personal experience when I say that I am aware of the most lamentable results of the 'cramming' process in medical students. I have been a teacher in medical schools for nearly twenty-five years. In the course of my examinations it has often happened that I have put a question in one branch of medicine to a candidate for graduation and have received an answer in an entirely different branch."

The absurdity of the answers sometimes given by medical students during the final examinations would be amusing if it were not so frequently an evidence of the pernicious methods to which Dr. Hammond here refers. This is exemplified in almost every examination of students for the medical degree.

We entirely agree with Dr. Hammond in his scathing denunciation of grammar as a subject of study in schools. We would willingly see it "banished from all schools," and would not even except, as he does with a reservation, "the senior year of a university course." No child, he truly says, "ever learned to speak good English from studying grammar. It has driven many a poor little wretch into headaches and other nervous troubles. It is the most ingenious device for forcing an immature brain into early decrepitude that the cunning of man has yet devised. The only reason why it does not do more harm is that not one in ten of the pupils that come out of our schools know anything about it."

In addition to grammar, we would like to banish from all schools that "idiotism" called "mental philosophy," which no sane boy or girl ever can comprehend; and, from girls' schools especially, geometry and trigonometry, which not one in five hundred understands, and not one in ten thousand has any use for in after-life.

We do not plead for a grossly utilitarian scheme of studies in the schools. That would be equally absurd with the present system. But, as professional men, conversant with the evils to physical and mental health which characterize our present public school methods; as citizens, interested in the highest development of the men and women who shall represent our national life; and as parents, solicitous for the well-being of our offspring, we have a right to demand that school boards and teachers shall heed our warnings. Among physicians and students of hygiene this question has been long discussed and reforms agitated. Dr. Hammond has preached his lay sermon to a wider congregation. Let us hope that his exhortation will bring those in fault to an early repentance.

ARCHIBALD MALMAISON has a counterpart in real life. A preacher, sixty years of age, left his New England home, settled in Norristown, Pennsylvania, and went into business. Six weeks later, consciousness of his identity suddenly returned to him. A further account of this will appear shortly.

NOTES FROM SPECIAL CORRESPONDENTS.

PARIS.

TREATMENT of Pleurisy in Paris.—A recent clinic of Professor Jaccoud's and a long discussion at the Société Médicale des Hôpitaux upon the treatment of pleurisy permit us to communicate the ideas of prominent medical men here with regard to this disease in its different manifestations. Professor Jaccoud spoke of the "Indications for Thoracentesis in Acute Pleuritis." He presented two patients, and instituted different treatment in each one. The patients were both wagon-drivers, one aged 30 and the other 40, and both had had apparently good health up to the present attack of acute pleurisy with considerable effusion. One of them had entered on the eleventh day and the other on the sixteenth day of illness. In both of them signs were found of tubercular alteration at the summit of the lungs, and therefore the prognosis was not very favorable as to ultimate results. The only apparent difference between them was that No. 29 had slight fever, and in No. 12 the disorder was apyretic. Then as to the quantity of liquid there was a difference. The effusion in No. 29 was already large when he entered, and it continued to increase almost under the eyes of the attendants, filling the pleural cavity to completion, as the percussion-sounds showed; while in No. 12 the liquid did not occupy more than the inferior two-thirds of the thoracic cavity; but it was on him that Dr. Jaccoud practised thoracentesis, while abstaining from doing so on the other patient. The only reason he gave at the time was that one was a right pleurisy and the other a left; but now he explains his action as follows: "It must be always remembered that dyspnœa is not the only indication for thoracentesis. Certainly it is a very important one when it exists, and when caused by the effusion; but there are plenty of patients, like these two, who have no dyspnœa at all, and a particular interest resides in such cases as regards the opportunity of paracentesis. First of all, the side must be taken into account. In right pleurisies there is no immediate danger, as a rule, and, if the febrile process has not ceased, internal medication can be tried with a fair promise of success; but if the patient be not seen until it is too late,—that is, when all the febrile disturbance is over,—then nothing can be hoped for from medicine, and aspiration becomes obligatory at once. In left-sided cases of effusion, without dyspnœa, the principal point is to notice the quantity of the liquid and the displacement of the heart and other organs; the functional symptoms are not of so much account. If the patient has arrived at the apyretic stage, and there is no displacement of the heart or liver, then wait; and this is why the therapeutics differed in the two cases. In No. 12 the indication was to operate at once. The effusion occupied two-thirds of the cavity, but the heart was displaced to the right at least two fingers' width from the right sternal side.

"However, notwithstanding these practical rules, if you have a doubt about this matter, always practise thoracentesis in any given case; because, when properly performed, it is always an innocent operation. But do not forget the precautions that Professor Dieulafoy often speaks about: which are, *never to empty the pleural cavity entirely*, nor allow the liquid to flow out too quickly. Give time for the lung to expand, and stop if the cough becomes too fatiguing; because it may be caused by the influence of the air compressing the lung. This is the indication to stop the discharge of fluid; but, as a rule, the quantity should not be over twelve to thirteen hundred grammes (over a quart). The classic precept given is to make the puncture in the axillary region; but this must vary with the patient, and it should be practised in the region where there is the greatest effusion. The second patient, who was not aspirated, was submitted to the tartar-emetic treatment, with drastic purgatives, and from the administration of thirty grammes of the *Eau de Vie Allemande* (a tincture of jalap and scammony) and thirty grammes of syrup of buckthorn (Rhamnus catharticus) he rapidly improved."

The case presented for the consideration of the Medical Society was one of M. Debove's, which he called *latent purulent pleurisy*, and a discussion took place about the treatment of such cases. M. Debove himself said that the patient was a man of about 30, who had been ill for six months, more or less, before he came to the hospital, but his malady did not prevent him from working. Upon examination, a considerable effusion was found on the left side, with displacement of the heart. He was aspirated, and a quart of liquid of a sero-purulent nature taken away on several occasions, with the result that it came back again. He was then let alone, this time for two years, and engaged in light work about the wards. He suffered some, and his digestion was bad, but still he was in passable health, and Dr. Debove thought best to abstain from all treatment, and he asked the opinion of his fellow-members with regard to the management of these cases of latent pleurisy, which had been described by De Mussy and Dieulafoy.

Dr. Rendu, of the Necker Hospital, and Dr. Bucquoy, of the Hôtel-Dieu, thought that in such a case it was well to commence by successive operations and allow the lung to dilate, and then, when the pleural cavity was small enough, practise an empyema operation, to be followed by Estländer's operation

or not, according to the indication. Dr. Dumontpallier said he was not a partisan of aspiration,—that might be repeated forever; but that as soon as an effusion was shown to be purulent he would advise large incision under antiseptic methods. He was not at all in favor of aspirating instruments, but thought the puncture should be made with an ordinary canula, so that it would be the elasticity of the lung alone that would push the liquid out: as it expanded, this and the movement of the thoracic cage would be enough to make the liquid flow out as the lung filled up. He was of the opinion that great harm might be done by sudden aspiration.

M. Debove and others concluded that, after the poor success they had seen from paracentesis, it would be best to abstain unless danger from asphyxia was present.

On the Action of Opium and Belladonna associated in a Case of Acute Diabetes.—M. Villemin, who is the Professor of Medicine at the Val de Grâce (military) Hospital here, communicates to the Académie des Sciences an interesting article on the above subject. He says "that he had lately a therapeutic fact that was as precise and as clear as any physiological experiment. It was that of a young artilleryman of strong constitution, who was admitted with acute diabetes with all its usual symptoms, consisting of a polyuria of fourteen litres a day, and discharging eight hundred and forty-one grammes of glucose in the same period. The usual treatment was at once commenced by ordering abstinence from sugar, etc., and giving meat-diet with the gluten bread, etc.; but, a week having passed without any improvement, Dr. Villemin thought of a case of diabetes insipidus that he had seen cured with belladonna and opium, and began to try it in this man. He feared at first that he might provoke an accumulation of glucose in the system by putting a check on the urinary secretion by this medication. But, however, he began by giving ten centigrammes of extract of belladonna and five centigrammes of opium extract per day; and seven days afterwards the urine had gone down to ten litres, and the sugar to four hundred and ten grammes. He then progressively increased the dose, and at the end of two months got up to fifteen centigrammes of each medicine, when he had the satisfaction of seeing the urine and the sugar eliminated diminish gradually. At this time the urine was from three to four litres, and sugar two to five grammes per litre, and the dose of the medicines was raised to twenty centigrammes, when, a week afterwards, there was not the slightest sign of sugar.

M. Villemin then suppressed all drugs, and in two or three days the sugar came back, so he was forced to return to the same dose, when, five days later, the sugar had again disappeared and the quantity of urine was now two litres. The cure was maintained as long as the medicine was continued; but the moment the dose was lowered or stopped, the sugar would reappear and the urine increase in quantity. During all this period of experimentation the patient was kept on the usual diet; but this was now changed, and he was permitted to use all kinds of food as he liked, or what was given to the healthy men. But this did not make any difference as long as the dose of twenty centigrammes was kept up. Later bromide of potassium was tried; but the sugar returned and the urine increased to eleven litres. Experiments were also made, by giving one only of the medicines, to see if either of them had a preponderating action or an exclusive one in modifying the disease, and it was seen that the results obtained were by the association of the opium and the belladonna.

Contagion in Febrile Exanthemata.—Most writers are silent on the point as to the exact moment when the eruptive fevers are contagious, and the general public opinion is that they are all catching during the period of convalescence. Dr. Girard, of Marseilles, says this idea must have come from physicians originally, as the people get all their medical ideas first from the doctors, directly or indirectly. He himself had held this notion; but, after a careful study of the matter in some one hundred and fifteen cases, first he found that it was the reverse of true, and, following up the subject for some years, he cites a large number of facts to prove that *contagion in these fevers always takes place at the very beginning of the disease*, and he found that the incubation takes, as a rule, fourteen days. Cases are given of varicella, measles, and smallpox to prove this statement.

Dr. Girard now tells his patients, when they want to send their other children who may not be attacked out to the country, "No; it is useless. If they are to have it, they have got it already from the one who is ill." In regard to measles, he also does not believe that children get it a second time, for it will be found, on examination of such attacks, that the eruption is not the same, the marks are not of the characteristic half-moon shape, nor are the usual oculo-nasal catarrh symptoms found in such cases. He gives a very striking case to prove that contagion takes place at the beginning: it was a family who had several children ill with varicella, and the pustules were not yet dry, when a relation having two healthy children arrived on a visit. The doctor was asked his advice, and, being firmly persuaded that the disease was only catching at first, he permitted the children to remain and play with the others without the slightest danger to them, or either of them, taking the complaint. This is, of course, a negative fact, but, taken as coming after a

large number of very positive ones, it seems to confirm the idea that these fevers are contagious from the first.

Treatment of Neuralgic Sore Throat.—Most practitioners of medicine have frequently noticed, upon inspecting a supposed sore throat, that, much to their astonishment, there was but very slight redness of the fauces, and that it could not in any way account for the painful sensations described by the patients. Dr. Huchard says that these cases are not inflammatory angina at all, as the pain is not owing to the inflammation itself, but they are what he calls "neuralgic angina." These cases are similar to those congestions or slight uterine hemorrhages that are associated with lumbo-abdominal neuralgia, or those ocular hyperæmias that are provoked or at least kept up by facial neuralgias. The following are the clinical characters that will enable us to diagnose them: 1st. An entire discordance between the pain and the superficial inflammation of the tonsils, etc. 2d. Entire subordination of the hyperæmia to the neuralgic symptoms, which last precedes all inflammation and often survives it. 3d. The character of the pain is not continuous, but manifests itself by paroxysms, which take place apart from deglutition, and increase at night. It is also very rarely isolated, but has other neuralgias (facial, occipital, cervical, etc.) at the same time, and it is frequently complicated with otalgia, which is much more violent than in other inflammatory forms,—when seen with tonsillitis, for instance. These pains are frequently so violent that one is disposed to think of meningitis.

These clinical facts command the following therapeutic indications. The treatment must be directed more against the neuralgic element than against the congestive one: so that all emollients and antiphlogistic remedies are useless. To fulfil the pathogenic indication, Dr. Huchard advises the following antiperiodic and antineuralgic medicines:

℞ Quininæ sulphatis, 20 centigrm.;
Ext. aconiti radicis, 1 centigrm. M.

Fiat pil. (one). Sig.—Give three such pills, at an hour's interval, in the morning. When the neuralgic pains are very intense, give a cachet of hydrobromate of quinine, twenty-five centigrammes, in which put a granule of aconitine of one-quarter milligramme size, and give it three times a day.

As to local treatment, order the pharynx to be touched two to four times a day with a little of the following mixture on a brush:

℞ Glycerini (puri), 10 grm.;
Morphinæ hydrochloratis, 10 centigrm.
Aquæ menthæ piperitæ, 4 gtt. M.

The peppermint acts by its "antalgic" properties, as shown by Delioux de Savignac and others.

In all very painful sore throats accompanied by spasmodic cough, the following formula may be used locally in the same way:

℞ Glycerini (neutral.),
Aquæ menthæ piperitæ, āā 10 grm.;
Potassii bromidi, 5 grm.;
Cocainæ hydrochloratis, 50 centigrm. M.
Sig.—Paint on part as required.

Flatulent Dyspepsia.—Before closing Dr. Huchard's prescriptions, we would like to give one that he gives very often in the above disorder when it is the pure atonic form, without acidity or heartburn, but simply discomfort, pain, and flatulency. His idea is that there is present a decomposing fermentation, and therefore the indication is the anti-ferments:

℞ Aquæ aurantii florum, 100 grm.;
Aquæ melissæ, 50 grm.;
Aquæ chloroformi (saturated), 100 grm.
M. Sig.—Take a dessertspoonful before each meal.

About the middle of each meal take a glass of oxygen-water. The oxygen-water ordered is now manufactured in Paris by a firm who have a process for making oxygen gas, and they deliver it in siphons, like the familiar ones seen in all the hotels and restaurants and supposed to contain seltzer water.

The writer strongly advises the use of the above formula, as he has seen great benefit from it in a number of cases of flatulent dyspepsia. The oxygen-water might be replaced by some natural spring water with but little gas in it.

Paris Hospital Therapeutics.—It may be useful to give in a short way, as complete as possible, the kind of medicinal treatment employed in the hospitals, and we take the service of Professor Germain Sée as a guide. The following is from the official book of the Salle (or Ward) St. Jeanne, Hôtel-Dieu:

Fed.	Diagnosis.	Treatment.
1.	Anæmia	Hemoglobine and pepsin.
2.	Chlorosis	Sodii arsenias.
3.	Zona	Antipyrine, 4 grammes.
5.	Hemiplegia	Todd's potion.
9.	Peri-uterine phlegmon	Injections, terpine, nux vomica, and gentian.
12.	Syphilis, cerebral	Biniodide of mercury, sulphur-baths.
12 (bis).	Chlorosis	Ferri et potassii tart., sulphate of aconitine.
14.	Albuminuria	Tannin pill, ergotin pill, terpine pill.
14 (bis).	Mitral insufficiency	Sparteine sulph., convallamarin.
15.	Pericarditis and aortic ret.	Iodide of potass., digital., sparteine.
18.	Myocarditis	Caffeine, sparteine.
20.	Thoracic varix	Tinct. hamamelis, antipyrine, Vichy water.
22.	Typhoid fever	Charcoal powder, naphthaline, quinine sulph., rectal injections.
23.	Amyothropsia	Pill opium, mercurial frictions.
24.	Mitral insufficiency	Digitalis infusion.
25.	Dyspepsia	Charcoal powder, benzoate of soda, terpine.
26.	Diabetes	M. Sée's régime, arsenic.
27.	Hydroarthrosis	Antipyrine.

Bed.	Diagnosis.	Treatment.
28.—	Phthisis	Arsenic, pill opium.
29.—	Dilatation stomach	Ipecac powder (5 centigrms.), cocaine hydrochl. (5 centigrms.); suppress all vegetables.
29 (bis).—	Not made	Jalap.
30.—	Emphysema	Terpine, iodide of potassium, pill opium, sparteine sulphate.

Of course, in this rapid list of actual patients and treatment we have not time to indicate the symptoms for which some of the remedies were given; but those accustomed to hospital practice will see the reasons and be able to compare the above with their own practice.

More Changes at the Paris Faculty.—You will probably have already noticed the death of Professor Béclard, the eminent physiologist, who was dean of the Paris Faculty. He had gone to a dinner given in honor of the nomination of Professor Farabeuf to the chair of Anatomy, and returned walking, with the result of being carried off in nine days with pneumonia. The regretted professor will most likely be replaced as Professor of Physiology by Professor (*agrégé*) Ch. Richet, who is the son of Professor Richet who holds one of the chairs of clinical surgery at the Hôtel-Dieu. The position of dean will probably be given to Professor Brouardel, who is the Professor of Legal Medicine at the Faculty, and whose name is connected with all the medico-legal cases in Paris. He will receive three nominations at once shortly: one to the Academy, one as dean, and one as physician to the Hôtel-Dieu in place of Dr. Gallard,* who died lately. M. Brouardel is still in the prime of life, and he is a most eloquent speaker, attracting the largest audiences at his lectures at the Faculty. He is also a very amiable man, with great influence in the world of science and politics, so that this, combined with his thorough knowledge of his functions, will make him a great acquisition to the Paris Faculty as their dean.

Thomas Linn, M.D.

Paris, February 23, 1887.

WASHINGTON.

THE INTERNATIONAL MEDICAL CONGRESS: DISTINGUISHED VISITORS EXPECTED—THE MEMORIAL TO SURGEON AMBLER—SURGEON-GENERAL MOORE AND SECRETARY ENDICOTT—THE YELLOW FEVER INVESTIGATION.

Washington, March 22, 1887.

THE preparations for the Ninth International Medical Congress are being pushed with energy by the several local sub-committees. The Sundry Civil Bill, as finally passed, appropriates ten thousand dollars towards defraying the expenses of the Congress. The Senate had adopted an amendment appropriating thirty-five thousand dollars, but a member of the House Appropriations Committee is said to have threatened the defeat of the entire appropriation unless the reduced sum was accepted by the Senate conferees. The bill contains a provision that the sum appropriated shall be expended only on vouchers approved by the Secretary of the Interior.

This amount, while of material assistance, is totally insufficient to cover the extraordinary expenses incident to the Congress. Hence it will be necessary for the profession to respond promptly and liberally to any appeals that may be made by the Executive Committee for funds for the entertainment of the foreign guests who are expected.

The scientific success of the Congress is no longer in doubt. Of the large number of foreign delegates who have accepted invitations and signified their intention of being present, the more prominent are the following:

Drs. E. Landolt, A. Chervin, Dujardin-Beaumetz, M. Magitot, P. Ménière, W. D. Hogg, A. Charpentier, J. Amédée Doléris, Marquis Nadaillac, B. Löwenberg, Léon Petit, Victor Audhui, Henri Picard, P. Budin, M. Durand-Fardel, P. de Pietra Santa, and H. Leloir, of France.

Surgeon-General Jeffry Marston, John A. Macdonald, Dr. Evatt, Sir William Alexander Mackinnon, Sir Thomas Longmore, Sir James A. Hanbury, F. Bowreman Jessett, Urban Pritchard, J. H. Galton, J. Jamieson, Alexander Russell Simpson, F. P. Staples, John Anderson, A. Watson, Joseph Ewart, Dr. Lofthouse, E. H. Roberts, Alfred Pearce Gould, W. Allan Jamieson, William MacEwen, Isambard Owen, C. D. F. Phillips, J. G. S. Coghill, Ralph Stockman, William Murrell, Sidney Martin, Edmonston Charles, P. A. Young, Alfred L. Galabin, T. Colcott Fox, George Thin, Jonathan Hutchinson, M. Ludlow Purves, F. M. Pierce, J. J. Kirk Duncanson, R. N. Wolfenden, John Sutliff, Dudley W. Buxton, John Hutchinson, George Johnson, Sir E. H. Sieveking, S. A. M. Gordon, A. T. H. Waters, Walter Pye, William Frazer, Arthur Mitchell, M. Julius Mickle, H. Charlton Bastian, John Simon, David Ferrier, W. A. Brailey, Henry Power, J. William Moore, D. Hack Tuke, J. Syer Bristowe, W. Howship Dickinson, P. H. Pye Smith, C. Macnamara, J. W. Hulke, Christopher Heath, Richard Barwell, William Anderson, Thomas Bryant, Edmund Owen, Arthur W. Orwin, George H. Savage, W. M. Whitmarsh, J. William Taylor, Thomas More Madden, Robert Gray, McCall Anderson, Eustace Smith, Charles West, T. M. Dolan, J. W. S. Thudichum, Benjamin W. Richardson, J. Comyns Leach, H. B. Hewetson, George Gray, Julius Althaus, Lawson Tait, Sir J. Crichton Browne,

* Dr. Brouardel will not, however, take Dr. Gallard's service, of women's diseases, but one of medicine.

W. Dunnett Spanton, and E. Radcliffe Cousins, of Great Britain.

Drs. A. Hegar, Christian Bäumler, A. Gusserow, Joh. Veit, A. Oldendorff, F. Winckel, A. Wernich, L. Lewin, P. G. Unna, O. Lassar, Surgeon-General Von Coler, F. Esmarch, Dr. Schwartze, and A. Eulenburg, of Germany.

Dr. Leopold Servais (official representative of the Belgian government), Professor Hauben, and Dr. Alfred Struebens, of Belgium.

Dr. O. Chiari, Gustav Braun, Emil Ehrendorfer, Alois Monti, H. Widerhofer, E. H. Kisch, Joseph Körösi, Moriz Kaposi, Hans von Hebra, Isidor Neumann, Johann Schnitzler, Dr. Neudörfer, of Austro-Hungary.

Drs. A. Cordes and F. Dumont, of Switzerland.

Professors J. W. R. Filanus, A. Guye, and Dr. Gori, of Holland.

Drs. Domenico Chiara, W. W. Baldwin, Andrea Ceccherelli, Luigi Casati, Eugenio Fazio, and Domenico Peruzzi, of Italy.

Professor Hirschsprung, of Denmark.

Dr. Miguel Gonzalez Gonalsey, of Spain.

J. A. S. Grant (Bey), of Egypt.

Dr. Leonard Boor, of New Zealand.

Dr. Moncorvo, of Brazil.

Dr. H. Reimann, of Russia.

Professor T. W. Kay, of Beyrout, Syria.

This list of names looks sufficiently international, and most of them are pretty well known to students of current medical literature. It is true we shall probably not be able to get Bismarck, Boulanger, Schwenninger, or Señor Ferran, because we cannot promise that they will meet "the leaders of professional thought"—certain able editors and their assistant kickers in Boston, New York, Philadelphia, and Baltimore—at the Congress. On account of a change in administration, both of the country and of the Congress, we shall not be able to pay the travelling expenses of the foreign delegates. This may keep some of the very prominent ones at home. All those that come, however, will find a hearty American greeting awaiting them, and during Congress week, at all events, the latch-string will hang outside.

The Committee on Entertainment is actively engaged in preparations for the entertainment of the distinguished guests. No one need fear that the social features of the Congress will be neglected.

The Committee of Arrangements has secured the following places of meeting for the Congress and the various sections.

The general meetings and the sessions of the Sections on General Medicine and on Dental and Oral Surgery will be held in Albaugh's Theatre.

The Sections on General Surgery, Military and Naval Surgery, and Dermatology and Syphilis, in Cornwell's Building, Pennsylvania Avenue.

The Sections on Anatomy and Pathology, in the Army Medical Museum.

The Section on Physiology, in the United States National Museum.

The Sections on Obstetrics and Gynæcology, in the Georgetown Medical College.

The Sections on Materia Medica and Therapeutics, and Psychological Medicine, in the National Medical College.

The Sections on Medical Climatology and Dermography, and Public and International Hygiene, in the Masonic Temple.

The Sections on Otology, Laryngology, and Ophthalmology, in Columbia Medical College.

The Section on Diseases of Children, in Willard's Hall. This will also be the headquarters of the local committees and the place of registration.

The rates at all the principal hotels have been reduced to three dollars and three dollars and a half per day.

The medical officers of the navy have just had completed a beautiful tablet in bronze, commemorative of the heroism of Surgeon J. M. Ambler, who perished with De Long and his companions in the Lena Delta in 1881. It will be remembered that when the "Jeannette" was crushed in the ice and sank in June, 1881, the exploring party took to the three boats, and that two of the latter reached land in the Lena Delta on September 16 and 17. The third boat, containing Lieutenant Chipp and seven men, was lost, no trace of it ever having been found. Reduced by cold, disease, and starvation, those who had escaped the sea searched for their missing companions, but without success. Lieutenant Danenhower and Engineer Melville, with nine others, succeeded in reaching home after undergoing many privations. The captain's party consisted of fourteen, including Dr. Ambler and Mr. Collins, the meteorologist (a brother of Dr. Collins, of Minneapolis). Of these, only two seamen, Nindermann and Noros, who had been sent ahead for assistance, escaped. The others, worn out and hopeless, "fell down and died as they walked along," Captain De Long, Dr. Ambler, and a Chinaman, Ah Sam, being the last to succumb.

The tablet, which is of bronze, encased in a heavy oak frame, illustrates in a very spirited manner a scene on the 9th of October, 1881, when Nindermann and Noros are leaving the camp for succor. At this time the party were living on three ounces of alcohol per day, with no solid food whatever. The captain urged Dr. Ambler to accompany them and try to save himself; but the latter declined, saying his duty was with the sick and dying. Besides this representation, the tablet contains an oval medallion bearing an excellent likeness of Dr. Ambler, and his name and rank, with the legend, "Duty stronger than love of life," in decorative lettering.

The entire memorial is gotten up with ex-

cellent artistic taste. The conception and execution in all details are exceedingly creditable to the committee having the matter in charge and the artists, Messrs. Joseph Lauber and Charles R. Lamb, of New York. The tablet is now on exhibition at the Corcoran Art Gallery. It should be photographed under the auspices of the committee, in order that every one who desires may have a representation of this beautiful and characteristic memorial, which typifies in such an exquisite and impressive manner the qualities which all men honor.

The reported disagreement between Surgeon-General Moore and the Secretary of War has been much exaggerated in the newspapers. While there are reasons for believing that Dr. Moore was at first annoyed and offended over the apparent interference in the management of his office by the Secretary, it may be confidently stated that no resignations or retirements will follow as a consequence. Dr. Huntington was relieved from duty in the Surgeon-General's Office in pursuance of the principle established long ago by Secretary Endicott, that officers shall not remain on duty in Washington longer than four years if others can be found to perform their duties satisfactorily. Dr. Huntington had been for about sixteen years continuously on duty in the Surgeon-General's Office, and was granted a change of station. It is probable that other changes of a like character will soon be made.

A great deal of gossip is current with regard to the influence of Dr. Baxter in securing the changes that have been made, but there is nothing in the rumors. While Dr. Baxter is credited with having a good deal of influence with the Secretary of War, he is not the sort of man to use it unfairly.

The sum of ten thousand dollars has been appropriated by Congress to pay the expenses of an investigation into the alleged protective inoculations against yellow fever claimed by Dr. Domingos Freire, of Brazil, and Dr. Carmona, of Mexico. A large number of inoculations have been made in Rio de Janeiro and other cities in Brazil, and the results are said to substantiate fully the claims of Dr. Freire. An investigator with good judgment and thoroughly competent to perform the duty should be selected for this mission. It is generally believed that the choice will fall upon a distinguished medical officer of the army who is *facile princeps* in the department of bacteriology. The President may decide, however, that no special bacteriological knowledge is necessary in order to accomplish the purposes contemplated by the Act of Congress, and appoint some one else. It is said that among the applicants for the appointment is Dr. Joseph Jones, formerly President of the State Board of Health of Louisiana. Dr. Jones has had much personal experience with yellow fever, but his selection for the proposed investigation would not inspire much confidence among the members of the profession who look forward with interest to the solution of such a vitally important problem as the prevention of the most destructive scourge that constantly threatens our Southern border. G. H. R.

PROCEEDINGS OF SOCIETIES.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

THURSDAY, MARCH 3, 1887.

The President, THOMAS M. DRYSDALE, M.D., in the chair.

DR. E. LONGAKER read a paper on

TREATMENT OF LABOR IN CONTRACTED PELVES.*

The most frequent forms of contracted pelves are the flattened and the generally contracted. In the former the conjugate diameters alone are shortened, and in the latter all are less than normal. The paper was limited to the consideration of those cases where the narrowing is moderate and not sufficient to render the birth of a living child impossible. This embraces flat pelves having a conjugate of three inches or a little less, and generally contracted pelves having a conjugate of at least three and one-third inches.

Dr. Longaker here followed with a description of the peculiarities of the flat non-rachitic pelvis and the flat rachitic pelvis.

Reports of six cases were given. In Case 1, with a conjugate of three and one-half inches, craniotomy was performed, in consequence of the large size of the head and an unchangeable bad presentation of the head, after attempts to deliver with the forceps had failed. The mother ultimately recovered. A careful study of the change from a vertex- to a brow-presentation was followed by comments on the increased dangers in multiparæ, with a criticism on powerful traction efforts, first with one pair of forceps and then another, until three or four have been tried.

Case 2 was delivered with forceps of a living child.

Case 3 was also delivered with forceps of a living child.

Case 4. Rachitic flat pelvis, conjugate of three inches, second pregnancy, delivered by means of Tarnier's traction-forceps. Her first child had been born without assistance, after sixty hours of labor. A large portion of the posterior cervix had sloughed away as the result of this prolonged labor. The head

* Published in the American Journal of Obstetrics.

was transverse and semiflexed at the superior strait. He applied the forceps over the face and occiput, and delivered a living child. The mother did well.

Case 5 was a counterpart of the fourth. Tarnier's forceps were used, and mother and child did well. With version in contracted pelves he has had no experience. Under favorable circumstances, the operation can be done so easily that it may be regarded as without danger in itself.

Case 6 was a breech-presentation in a contracted pelvis, third pregnancy. The first child had been stillborn, the second was delivered alive by means of forceps. In this, the third labor, the extraction of the after-coming head was very difficult, and the child was still. The day after delivery, signs of internal hemorrhage and peritonitis appeared, and the mother died twenty-four hours after delivery. Rupture of the uterus and vagina was found at the autopsy.

Three other cases of uterine lacerations in breech-presentation in contracted pelves were given, followed by a study of the mechanism of this tendency to laceration. He came to the conclusion that it will be best to restrict version to cases in which there are other reasons for it than the mere existence of flattening,—some of these being the presence of the occiput on the smaller side of an unequally-contracted pelvis, the sagittal suture over the symphysis pubis, presentation of an ear, and prolapse of the cord. He extolled the axis-traction forceps in these cases, and exhibited an instrument of his own devising, which he had used in two cases. He has no hesitation in applying the forceps high up in the uterus when the head is arrested at the brim of the pelvis, and cited fifteen cases of such application in proof of his opinion. After some remarks on estimation of the conjugate diameter, he concluded with the following propositions:

In the flat pelvis and in the flat rachitic pelvis, decided degrees of disproportion at the brim may be overcome by the natural efforts when the head presents.

In the forceps, and especially in the axis-traction forceps, we have the means of extending still further the possibilities of successful delivery when the head is arrested at the brim.

The forceps, judiciously used, is a safe instrument for mother and child.

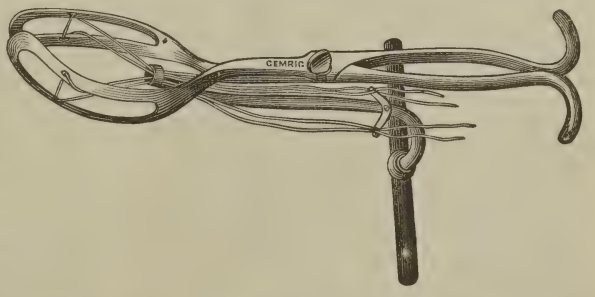
The existence of contraction of the pelvis in itself is no reason for preferring version.

In flat pelves, with a conjugate diameter of not more than three and a fourth inches and not less than two and three-fourths inches, premature labor should be induced.

Dr. HIRST differs from Dr. Longaker on two points: the propriety of always applying the forceps in flat pelves before the head has become engaged, instead of turning and delivering by the breech; and the propriety of applying the forceps over face and occiput in transverse positions of vertex-presentations, as in this latter operation the biparietal diameter must be increased.

Dr. H. A. KELLY agreed with Dr. Hirst. He considered the paper of Dr. Longaker a very timely one, which in all its leading features he most heartily commended. It is certain that an intelligent use of the axis-traction principle is destined to revolutionize the treatment of labor in contracted pelves. In cases in which craniotomy has been the custom, axis-traction will save many lives. A few important rules should be borne in mind. First of all, Dr. Kelly would differ from the speaker most decidedly in one practice, and lay down the rule that "axis-traction" cannot be applied to the head above the brim. There is no axis above the brim, and any traction on the rod merely causes the head to rotate around its own axis, but can under no circumstances be efficient in inducing it to engage. Axis-traction applies to heads engaged in the pelvis. Again, the ordinary use of this principle should be to *assist the pains*. Further, it is important in using Tarnier's forceps of this model to attend constantly to keeping parallel the shanks of the prehensile blades and the proximal end of the traction-rod.

If the handles of the forceps rise during a traction, and it is felt by the examining finger that the head has not really advanced, then either the head has rotated in consequence of an eccentric grip or the forceps has slipped; and here lies the great difficulty of the Tarnier instrument. The frequency of this accident, together with some other considerations regarding the mechanical construction of the instrument, had demonstrated to his mind the fact that it is only approximately axis-traction. He showed a pair of forceps (see illustration) with which he had delivered a dwarfed woman of a full-sized, live, female child through a three-inch conjugate. This pair of forceps was shown him first by Dr. Porak, of Hôpital St.-Louis, Paris, who believed that by them he had attained the most perfect axis-traction yet devised. The principle



is applied in a very simple manner to any long forceps. Each of the four blades of the spoons is perforated with a small oval hole, as near the centre of the oval of the spoon as possible. Two long tapes are taken, and one passed through the holes of one side; the four free ends are brought down under the forceps, and, after their application, hang out at the vulva. These ends are brought through a hole at the extremity of a traction-rod curved as ordinary traction-rods, with the usual transverse handle at the outer extremity; this is then drawn up to the head, and the ends of the tapes fastened on the rod at the apex of the angle where the vaginal turns down into the perineal curve. The advantages of this forceps are many. 1st. The application is extremely simple. 2d. It can be applied to any forceps. The Tarnier cannot be, as it is only suitable to narrow-heeled instruments. 3d. The child's head is grasped by the centre of its figure, owing to the position of the attachment of the tapes. 4th. This same factor renders unnecessary the screws which are so dangerous in Tarnier's forceps, as the traction does not tend to force the blades apart, but approximates them. 5th. The perfectly movable connection between forceps and rod—*i.e.*, the tapes—allows the head to flex and follow the curve of the pelvic canal.

He had used Tarnier rods and the Poullet forceps on the same patient several times, and his experience accords with that of Dr. Porak: where the Tarnier rods fail and the forceps slip, the Poullet forceps hold and work easily.

Dr. Kelly said, "An interesting incident of a short time since shows the comparative value of axis-traction. I had described my Poullet forceps to a friend who has a large obstetric practice. He sent me a note, asking me to bring my French forceps. I found the head well engaged, but wedged tight. He had made many well-directed vigorous efforts with his own forceps, and finally gave up in despair, producing no effect. I applied the Poullet forceps, and, with a moderate traction on the rod, the head moved gently and steadily until it came directly to the outlet without apparent effort. We were both enthusiastic. No ordinary forceps in the world could have accomplished that." Mr. Gemrig, of this city, keeps the rods on hand: they are the only essential part of the instrument.

Dr. CLEEMANN: There is one feature of Tarnier's forceps which appears to be barbarous and unscientific, and I see this feature is retained in the instrument shown. I allude to the device of the screw, which is intended, by clamping the blades against the child's head, to prevent the slipping of the instrument. Slipping should be prevented by the proper adjustment of the blades to the child's head and the moderate pressure induced through traction. To accomplish such adjustment in extreme cases, a pelvic curve should be given to the shank of the instrument. Such adjustment cannot with safety be replaced by the mechanical pressure induced by the screw. (*Amer. Jour. Obstet.*, April, 1878, p. 341, *et seq.*)

Dr. LONGAKER had not had time to read Dr. Winten's article in the original, *Zeitschrift für Geb.*, but gained his information from an editorial in the *Medical News*, which stated that an expectant plan of treatment and forceps are advised for primiparous, and early version for multiparous.

He still thinks the occipito-frontal application of the blades does not appreciably increase the biparietal and bitemporal diameters of the fœtal head. It may increase the vertical diameters, as the cervico-bregmatic and sub-occipito-bregmatic. A simple experiment on the manikin of Budin demonstrated the truth of this proposition. A full-term fœtus, stillborn, was placed in position at the brim, the sacrum being thrown forward so as to make the conjugate measure three inches. With the axis-traction forceps, the relative disproportion between the head and the pelvis, which was considerable, was easily overcome. With blades having a sufficiently marked cephalic curve the compression need be but slight.

There seems to be some misconception as to what is meant by the head being at the brim of the pelvis. The head is at the brim until the greatest transverse diameter, the biparietal, has passed the plane of the superior strait. With a head entirely above the superior strait, the use of any forceps would hardly be appropriate. If fixation of the head could not be secured, version would be the best measure.

He did not see how traction exerted by means of tapes could be more efficient than with stiff rods.

The fixation-screw is a necessity, there being no free hand to make the necessary compression by the handles. Moreover, it is not objectionable. Continuous pressure is avoided by relaxing the pressure in the intervals. This was one of the chief objections urged by the late Albert H. Smith.

A little reflection and application of well-recognized principles would dictate the proper method of applying traction. Simple axis-traction forceps have been devised by Breus and by Braun.

As version is in almost universal favor in Germany and Vienna, these instruments have little chance; they are scarcely used there.

Dr. BARTON C. HIRST read a paper on

THE DEATH-RATE OF LYING-IN HOSPITALS IN THE UNITED STATES.

Of nineteen thousand nine hundred and two women, delivered in thirty-four hospitals during the years 1880 to 1885, distributed among nineteen large cities of this country,

2.59 per cent. died after childbirth. This death-rate compares very unfavorably with the statistics of hospitals in England, Germany, Vienna, and Paris, and is also more than twice as great as the death-rate of general practice in the cities of this country, which is about one per cent. One and a half per cent. of the women confined should be the maximum death-rate in lying-in hospitals, and, to secure this result, those institutions should be subjected to State or municipal supervision.

Dr. BALDY thought that, in comparing American lying-in hospital reports with those of foreign countries, especially those of Germany, we would not find the former to hold an inferior position. According to Dr. Dohné's statistics, the average mortality in Germany before antiseptics were introduced was 3.4 per cent. Comparing this with the 2.5 per cent. mortality as given by Dr. Hirst for American hospitals, we stand about even,—our apparent advantage being due to the fact that their 3.4 per cent. were without any antiseptic, our 2.5 per cent. included a few years of antisepsis. Comparing the years of complete antisepsis in both countries, we still hold our own, Dr. Dohné giving the German an average mortality of 1.37 per cent., Dr. Hirst giving us a mortality of 1.31 per cent. for the Boston Lying-in Charity, and 1.52 per cent. for Blockley Almshouse, Philadelphia, with a mortality of less than one per cent. for the past year in the last-named institution. The mortality of private practice and hospitals scarcely admits of comparison.

Dr. Baldy considers modern midwifery too meddlesome. The practice of introducing the examining finger and manipulating the patient every fifteen or twenty minutes is a great source of danger. This is evident on reference to Dr. Dohné's statistics. In hospitals, even under antisepsis, where students of medicine are taught, the percentage of mortality is given as 1.90; where midwives are trained, 1.13 per cent.; where there is no teaching whatever, 0.56 per cent.

Two great sources of puerperal fever, so called, are lacerations of the soft parts and diseased appendages. If the laceration were always dealt with primarily, and the appendages examined and dealt with as required, our mortality would drop to almost nothing. While he was an interne at Blockley Almshouse, the vast majority of women delivered suffered from perineal tears, and in every one of these cases there was a rise of temperature that was called puerperal fever. There were no attempts at closure and no antiseptic precautions. A patient is now under his care who was delivered a month ago of a stillborn child. On the third day she experienced a rise in temperature, with all the signs of a puerperal fever. An examination disclosed a pyosalpinx, which will have to be removed to save her life.

Dr. HIRST admitted that before the introduction of antiseptics the statistics of German hospitals were worse than those of our hospitals at the present time.

PERINEORRAPHY AS PERFORMED BY DR. W. GILL WYLIE.

Dr. HOWARD H. PARDEE: The interest shown in the paper describing Dr. Emmet's operation for the restoration of the perineum, read at the February meeting, led me to think that a brief description of the operation devised by Dr. Wylie might also be acceptable to the Society.

According to a paper by Dr. Wylie, contributed to the *New York Medical Record*, March, 1885, he had devised this operation about five years previously. It was first performed before a class, so far as I know, in a ward in Bellevue Hospital, New York, in the winter of 1882–83. It is the operation as I then became acquainted with it that I shall describe, for it is the one I have since used and am most familiar with. A letter received from Dr. Wylie a few days ago tells me that he still uses the same operation, with little if any modification. It is performed as follows.

The usual preparation by laxatives, hot douches, and glycerin tampons having been carried out, the bowels are cleaned by an enema an hour or two before the time for operation. Just before the patient is etherized, a hot vaginal douche of corrosive sublimate, one to five thousand, or carbolic acid, one to forty, is given. The patient is placed on her back, the buttocks as near the edge of the table as possible, with the thighs strongly flexed and the knees held apart by an assistant on either side. The labiæ are drawn apart as fully as possible without straining, and are held by the assistants. The caruncles marking the posterior border of the vaginal orifice are found, and mark the limit of the denudation upward or towards the pubes. A tenaculum is hooked into the crest of the rectocele, which is drawn down, and an examination is made with the finger to find at what point the tissues on either side of it are put on the stretch by the traction. This point, or one a very little above it, is made the limit of a denudation backward into the vagina. It is well to mark it by snipping off a particle of the mucous membrane on either side. For the denudation, a pair of moderately sharp-pointed scissors curved on the flat is the most convenient instrument. Following Dr. Wylie's example, I have always used a pair of good dissecting-forceps to catch the tissues, instead of the tenaculum. Commencing from below, a strip of mucous membrane as wide as can be conveniently cut is snipped off, following the line of junction of the skin and mucous membrane from the level of the inferior caruncle on one side to the same level on the other. We then denude all the

posterior surface of the vagina up to this level till we reach the beginning of the sulci running on either side of the rectocele. The part of the operation requiring the greatest judgment has now come. Our object is to unite the vaginal wall above the sulcus on one side with the corresponding portion of the vaginal wall on the other side, so obliterating the sulci and forcing back the rectocele. If we carry our denudation too high, we shall find it difficult to bring the two sides together without undue tension. If we are too timid, our support will be insufficient and our operation will be but a partial success.

The proper level having been determined, we continue the denudation upwards till we reach the points in the vagina which we marked out as the limit of tension from the apex of the rectocele. This will usually be about one and a half or two inches from the orifice. In denuding this portion of the vagina, we still work from side to side, carrying the strip of mucous membrane down into the sulcus, up over the rectocele, down into the other sulcus, and up to the level we have marked on the other side. In doing this we should not cut very deeply, and preserve as much as possible of the muscular substance of the wall of the vagina over the rectocele; but afterwards we should go over our work in the sulci, removing all tissue, till we come to the firm fibrous external sheath of the vagina. In this way we hope to preserve a firm muscular coat over the rectocele. When we are through, the denuded surface will be nearly square, or, if the rectocele be very large, a parallelogram, the greatest length being transverse to the axis of the vagina. All bleeding should be controlled preferably by pressure and torsion, but, if necessary, catgut ligatures may be used, and the parts washed thoroughly with some efficient antiseptic.

The sutures should now be introduced. The first three or four are placed as in the old "butterfly" operation, entering about a quarter of an inch outside the line of junction of the skin and mucous membrane, passing backward and downward, and then upward and forward, emerging on the other side at a point corresponding to the point at which they entered. The last one of these external sutures should be entered a little above the level of the caruncle which marked the limit of denudation upward. The remaining sutures, four or five in number, are usually entered in the mucous membrane a little above the line of denudation, passed down below the angle formed by the sulcus, and up to the crest of the rectocele. It is best to bring the needle through at this point and re-introduce it at the same point; it then goes down the other side of the rectocele, round the angle of the sulcus, and up the opposite vaginal wall till it emerges above the line of denudation, opposite the point where it entered on the other side. This may seem to be a difficult stitch; but, with a straight needle, a good needle-holder, and the index finger of the left hand in the rectum, while the thumb is in the vagina, it is made without much trouble. The greatest care should be taken that the needle is buried when it passes under the angle of the sulcus. When the sutures are placed, and before they are tightened, the sphincter ani should be thoroughly stretched. This to a certain extent relieves the tension on the sutures, and at least adds largely to the comfort of the patient by preventing straining at stool. Another thorough cleansing of the parts should now be done, and the sutures should be tightened from below upward. The urine is not drawn unless the patient is unable to pass it; the parts are washed after urination.

Dr. PARISH had for years performed a similar operation, but carried his denudation farther up the vagina, and thus avoids the formation of a pocket-like place in which discharges accumulate. He has found it in some cases a cure for constipation.

Dr. BALDY did not think Dr. Pardee understood Emmet's operation.

Dr. PRICE prefers Emmet's operation.

Dr. H. A. KELLY thought this an unsatisfactory modification.

Dr. PARDEE was well acquainted with Emmet's operation as performed two and a half years ago. The obliteration of the rectocele in that operation was by drawing down a stretched wall, leaving it thin over the rectocele. In his experience, opium had not been needed after the operation to control pain. The external stitches are needed to secure a neat external healing.

Dr. JOSEPH PRICE exhibited a specimen of

DOUBLE PYOSALPINX WITH COEXISTING OVARIAN CYSTOMA ON BOTH SIDES.

Mrs. H., æt. 30 years, two children, labors normal, complains of irregular and profuse bleeding, constant pelvic pain, greatest on left side. General health poor. Examination revealed a small fibroid on posterior wall of the uterus, a cyst on the right side extending high up, and inflammatory masses laterally.

Operation.—On section, the appendages on both sides were found distended by pus and generally adherent; left ovary cystic and suppurating, and matted to the pavilion of the tube and the sigmoid flexure. The right ovary was cystic and adherent to the vermiform appendix. The pelvis was filled with an irregular conglomeration of cysts and pus-tubes, intimately adherent to pelvic organs, and overlying all this were the bladder and omentum, also firmly adherent. The omentum was perforated at two points, and the mass was removed by careful dissection. A glass drainage-tube was used; recovery was rapid and perfect; no opium, no catheter; tube out on fourth day; stitches out on seventh day.

Dr. W. H. PARISH reported a

PORRO-MÜLLER OPERATION,

performed by Drs. O. H. Allis and W. H. Parish because of an impacted shoulder-presentation. Mrs. L., æt. 26 years, of small stature but good general health. When about six months pregnant she had been hooked by a cow and narrowly escaped a miscarriage. She reached full term, and had been in labor seven days when Dr. Allis was telegraphed for by Dr. Groom, of Bristol, Pa., in whose care the patient had been. The membranes had ruptured four hours after the pains began. On the sixth day the pains became more severe and the cord prolapsed. About the same time a hand protruded from the vagina. The child died also about this time. Version had been tried by Dr. Groom and others without and with anæsthesia, but could not be effected. The child was evidently of large size. The patient was restless, exhausted, and with a pulse of 120 per minute. The pains were constant, and the uterus was firmly contracted about the child. The patient's surroundings were unfavorable: the ignorance and poverty of the family rendered proper nursing impracticable. An offensive sanious fluid was escaping from the uterus; the cervix was rigid and but slightly dilated. It seemed impossible to deliver the patient by either cephalic or podalic version, and the conclusion was made that evisceration was not advisable because there was every reason to believe that the uterus had done itself irreparable harm by reason of its prolonged retraction against the eminences of the child. The contusion incident to the retraction and the admission of atmospheric air over a period of seven days, with the character of the discharge, rendered it certain that gangrenous changes had been going on in the endometrium and placenta, and that septic inflammatory action of the uterine lymphatics had already begun. The patient was in a condition of exhaustion. Evisceration alone would not have sufficed to secure delivery: it would have been necessary to bisect the child in the lumbar region and to remove separately the lower and upper sections. The condition of the uterus and the small size of the pelvis would have rendered this procedure a lengthy and an exceedingly difficult one, and would have involved additional serious injury to the uterine tissues. The removal of the child would have left a putrefying endometrium and septic lymphatics. It was thought that the patient would certainly die if thus delivered. All present thought Cæsarean section warranted.

The operation was performed by Dr. Allis. The uterus was elevated from the abdomen, and a rubber tubing was placed about the cervix, securely controlling the hemorrhage. Escape of fluids from the uterus was guarded against by means of warm antiseptic pads adjusted about and over the abdominal incision. A vertical incision was now made, and the child extracted without difficulty; the placenta was not in the line of incision, and there was no hemorrhage. Two transverse pins were carried through the cervix, and a constricting wire was substituted for the rubber tubing about the junction of the cervix with the body of the uterus. With the uterine body were removed also both broad ligaments and their contents. The uterine stump was secured externally by means of the transfixion-pins, and wounds closed by carbolized-silk sutures. Antiseptic measures were taken throughout the operation, but the spray was not used. Immediately after the operation the pulse was 130 per minute. The patient died in forty-eight hours, apparently from heart-failure.

A full account of this case will be found in the *American Journal of Obstetrics*.

Dr. R. P. HARRIS remarked that the Cæsarean operation had been performed in the United States in cases of impaction of the fœtus in a transverse position twelve times. In eleven cases the fœtus was dead. In the twelfth it was saved; but the operation was believed to have been uncalled for by a physician who performed laparotomy with success after the woman had ruptured her uterus in her next labor. The pelvis had been computed to have a conjugate and a transverse diameter of three inches. In one other of the twelve cases the pelvis was deformed and the woman saved. The arm was protruding in seven cases, five of which recovered. In two the shoulder presented,—one saved; and in three the presenting part is not named. Of the twelve cases, nine, or seventy-five per cent., recovered. Of the three cases lost, one was ninety-six hours in labor, three days in charge of a midwife; another was twenty-six hours under a midwife who had given ergot and ruptured the membranes; and the third had been long in labor, but time not stated. Her death was caused by fright and exhaustion. She rose from her bed to defend her mother against her husband, who had come home drunk on the third day. He knew of but one case of impaction in Europe in which the Porro operation was performed; but in this the pelvis was deformed. The operation was by Fehling, of Stuttgart, and the woman was saved. Putridity of the fœtus may require the removal of the uterus in a case of impaction. One woman was saved without its removal, in the United States, after seven, and another after ten, days of labor, by uterine suturing to prevent escape of fluid; but it is safer to remove the organ when there is danger of poisoning, and particularly where the patient appears to be already threatened with it. In the Porro case of Candido Ramello, of Turin, the woman had been six days in labor, the fœtus was putrid, and the mother in great danger of septicæmia. The

removal of her uterus with its contents was followed by improvement of her symptoms, and she recovered.

W. H. H. GITHENS,
Secretary.

PHILADELPHIA ACADEMY OF SURGERY.

AT the stated meeting of the Philadelphia Academy of Surgery held March 7, 1887, the President, Dr. D. Hayes Agnew, in the chair, Dr. J. Ewing Mears read a paper entitled "The Progress and Limitations of Operations upon the Abdominal Cavity."

Dr. John H. Packard reported

A CASE OF GUNSHOT-WOUND OF THE ABDOMEN,

in which nine wounds of the intestines and one of the iliac vein were produced. Laparotomy was performed, and resection of a portion of the intestine was made, with closure of the other wounds by suture. The patient died in a few hours following the operation. At the autopsy the hydrostatic test showed that the closure of the wounds by the sutures was complete, and that all the wounds had been found and secured.

DISCUSSION.

Dr. J. Ewing Mears: Dr. Packard has alluded to the sutures to be employed in closing wounds of the intestine. Operators on the abdominal cavity have insisted upon the importance of using such a suture as will bring the serous surfaces fully together, and as much of the surface as is consistent with the preservation of the calibre of the intestine. Mr. Wells says that this is the great fact which has been learned from operations on the abdominal cavity in cases of ovarian disease. An important point with reference to the suture to be employed in closing wounds of the intestine is that one should be employed which will not permit separation under the influence of the peristaltic action of the bowel. The Lembert suture seems to me to accomplish that better than any of the other sutures which have been proposed.

In cases in which there is a wound of the liver, Dr. Senn has recommended that the wound be plugged with iodoform tampons, the tampon to be allowed to remain. If the wound is in an aseptic condition, the aseptic foreign material will, in course of time, become encysted. Suturing wounds in parenchymatous tissues, such as that of the liver, is a very unsuccessful operation. The needle employed in these operations should be round, and smaller than the catgut suture which it carries.

Dr. Charles B. Nancrede: Having been the first to perform laparotomy for gunshot-wound of the intestines in this city, although I was not then acquainted with Dr. Bull's and others' methods of operating, I recognized the objections to the triangular needle, and employed a cambric needle with very fine silk. I do not see that catgut has any advantage over fine silk. I was able in this way accurately to coaptate the wounds,—so accurately that, although the stomach (which had in its walls two large wounds) was forced out of the abdominal wound in the efforts at vomiting, and I had considerable difficulty in replacing it, nothing escaped. I used the Lembert suture, and it was perfectly air- and water-tight. My colleague, Dr. Forbes, in a case in which he resected about six inches of the bowel, used a combination of the Czerny and Lembert sutures which answered admirably. I do not think that the Gély suture would save any more tissue than the Lembert in ragged wounds of the intestine. When this subject was recently discussed at the meeting of the New York State Medical Association, I think most of the speakers recommended the use of the ordinary sewing-needle.

Dr. J. H. Packard: I used the triangular needle because it happened to be the best at hand; but it several times cut vessels in the mesentery or mesenteric border of the intestine of sufficient size to require tying, thus causing delay. I have since procured from Mr. Gemrig some needles made from ordinary sewing-needles of large size by cutting them off and re-sharpening them. The eyes are quite large enough to carry the fine gut which I used, and there is no lateral edge to endanger the vessels. The fine chromicized gut was used because it was in readiness, and I think it answered as well as silk.

The Lembert sutures were placed about one-eighth of an inch apart. For some reasons, Gély's suture seems to me preferable; but I should not make it continuous, as proposed by him. Instead of crossing the ends and re-inserting them in the intestinal wall, I would simply tie them, and start afresh. When used continuously, I should think it might produce an undesirable longitudinal puckering of the bowel. The advantages of it seem to me to be that it involves the turning in of less of the edges; that the longitudinal portion of it serves as a sort of splint for the tissues; and that some time is saved, as in each application progress is made along the wound as well as across it. I know of no recorded observations as to the comparative security afforded by these methods respectively.

The President, Dr. D. Hayes Agnew, presented a gallstone removed by cholecystotomy, and also a renal calculus removed by nephro-lithotomy.

DR. WILLIAM GOODELL having resigned from the Preston Retreat, Dr. Joseph Price has been unanimously elected to succeed him, as Physician in Charge, by the Board of Managers.

PHILADELPHIA CLINICAL SOCIETY.

STATED MEETING, FEBRUARY 25, 1887.

The President, Dr. JAMES B. WALKER, in the chair.

THE PRESIDENT introduced the subject of

ARTIFICIAL FEEDING OF INFANTS.

The importance of the subject all will admit, and depends upon (1) the inability of the mother to afford nourishment; (2) the demands of the child for the materials for growth, repair, and heat-production; and for *protection* from indigestion and the numerous disorders of malnutrition. The prominent indications of the non-agreement of any food are excessive colic, vomiting, diarrhœa. The results are seen in losses of flesh, strength, vivacity, and color, non-development of general body or of parts, as of teeth, retardation of infantile accomplishments, psychical or physical, or even loss of those which have existed. One or many of these conditions may exist and call for attention on the part of the physician to the imperative needs of the little patient.

In choosing a diet there is no established *law* save that the food shall be easily digested, non-irritating, and suitable for nourishment and heat-production. If the infant have been nursing its mother, the *quantity* may be alone at fault. In all such cases artificial food should be made to *supplement* and *not* to *substitute* the natural supply. The amount of artificial food must vary with each case from every alternate feeding to two or three feedings daily. Should the *quality* of the mother's milk be at fault, or should she be unable to nurse her child from other causes, a complete *substitute* must be furnished.

Here, unquestionably, the best, because furnishing the most rational substitute, is the wet-nurse. But, rational though it be, it has objections which sometimes are insurmountable. Among these are the expense incurred, the difficulty of getting one whose milk is altogether satisfactory, or, this agreeing, the unsatisfactoriness of the individual herself, who, reins in hand, may, if inclined, drive the family to distraction. Apart from this, many mothers object to having their little ones nurse at other breasts than their own, even when the substitute is cleanly in person, character, and habits, and much more so if doubt exist, as it often must, upon these scores. While not decrying wet-nurses,—indeed, while claiming that for some infants they are our only means of salvation,—the lecturer claimed that in most instances they are not indispensable.

In choosing a substitute for human milk for healthy children, the lecturer does not approve of the so-called infant-foods manufactured on large scale and kept on the druggist's shelves. These substances, many of which have much virtue, find a sphere in the management of the sick, but as a rule may be eschewed in arranging a food for the well.

For most babies condensed milk answers best for the first three to six months of life. Here again a choice may be made. There are several varieties of this food, most of which are supplied in quantities to grocers and druggists, and lie an indefinite time on the shelf or counter, during which time they are liable to deterioration. This is not a matter of theory, but has been proved in more than one instance by an attack of severe indigestion and diarrhœa on opening a new can. The brand most satisfactory in the lecturer's experience is Canfield's, which is manufactured in Philadelphia, and is for sale only at the manufacturer's office, where its freshness and purity are guaranteed. Or, if the sweetness of the condensed milk be an objection in an individual case, the "Evaporated Cream," a partially condensed milk prepared by the same firm, may be used, having it served fresh every day or every alternate day. Unquestionably, condensed milk is preferable for the young infant to the fresh (?) milk furnished by the middleman in our large cities.

If a child taking condensed milk is constipated, a small quantity of Mellin's, Horlick's, or Nestlé's food may be used in each bottle, and will usually be all-sufficient.

At least until a food has proved satisfactory, the infant should be weighed at the end of each week, and should gain from three or four ounces to a pound weekly. If severe colic, vomiting, or diarrhœa occur without cause, such as teething, exposure, etc., some change is indicated. This will usually be the case, where condensed milk is the diet, somewhere from the third to the eighth month. The addition of oatmeal to the food may be all that is needed. It should be thoroughly cooked for three hours, then strained through a cloth, producing a white, semi-translucent substance about the consistency of starch as used by the laundress. Of this from one to three tablespoonfuls may be added to each bottle, according to the age of the child and its powers of digestion. Lime-water is an important addition to the artificial food, and should be used continuously for the first ten or twelve months.

In most instances fresh cow's milk will have to be substituted for the condensed milk when the latter disagrees, or this, if obtainable pure, may be used from the first. This should be diluted to suit the age, and have added sugar, lime-water, and from a teaspoonful to two tablespoonfuls of cream to each bottle, varying the amount to suit the condition of the bowels. After the third month, or even before, some of the oatmeal-gruel, prepared as already directed, may be added. In cities, all the water used in preparing the food should have been previously

boiled. Sometimes an irritable state of the bowels, induced by one of many causes, may be benefited by the substitution for a few hours of barley-water, arrowroot-water, or gum-arabic water, and on resuming the milk-food one of the above waters may be used as the diluent, instead of plain boiled water. Sometimes the use of peptonized milk diluted with barley-water, or the addition to the milk-food of the "Peptogenic Milk-Powder" of Fairchilds, Brother & Foster, may be required for a shorter or longer period.

In the artificial feeding of infants the plain nursing-bottle with pure rubber nipple is better than spoon-feeding, giving exercise to the masticatory apparatus and stimulating to more rapid functional development the salivary function.

The subject was discussed by the different members, and the experience of each one proved that cow's milk in some form was the best food for a child who must be artificially fed.

Dr. ANNA MCALLISTER spoke of some interesting experiments which had been tried at the New York Infant Asylum, under the supervision of Dr. J. Lewis Smith: where, in several autopsies on artificially-fed infants, it was found that in those fed on *starchy* food the pancreas was very small, seemingly arrested in its development, while in those fed upon *condensed milk* the organ was normal in size.

Dr. EDWARD R. STONE gave a verbal report of a case of uræmic convulsions in nephritis following scarlet fever in a child 6 years of age, in which a hypodermic injection of one-twelfth grain of muriate of pilocarpine gave most satisfactory results. The child had been in convulsions all day, but they were speedily checked after the administration of the remedy, salivation and diaphoresis setting in almost immediately. "Basham's Mixture" was used afterwards, and the child made an uninterrupted recovery.

MARY WILLITS, M.D.,
Reporting Secretary.
1527 GREEN STREET.

NEW YORK ACADEMY OF MEDICINE.

A STATED meeting of the Academy was held March 3, 1887, the Vice-President, CHARLES C. LEE, M.D., in the chair.

THE PATHOLOGY AND TREATMENT OF EPILEPSY, BASED UPON NOTES OF SIXTY CONSECUTIVE CASES IN PRIVATE PRACTICE.

Dr. WILLIAM H. THOMSON read the paper. He observed that the most striking features of a disease were often the least important: this he considered to be true regarding the motor or convulsive phenomena in epilepsy, which are only accessory. He did not look upon epilepsy as necessarily a convulsive disorder at all. It had been said that its primary and essential element consists in an explosive or active discharge of nerve-cells. For this definition he would substitute the following: epilepsy is a disease characterized by sudden but temporary loss of function on the part of one or more cerebral centres, the attacks being introduced probably in every case by an afferent impression.

To illustrate his meaning he cited the case of a man who, although he had the convulsive phenomena of epilepsy, had at other times only sudden and temporary aphasia, not being unconscious; at other times there was a loss of consciousness and a convulsion; there was also the initial aura. He asked what these different attacks were, if they were not true epilepsy? and, if so, how could the motor or convulsive phenomena be absent and yet be an essential element of the disease? He therefore claimed that the essential and invariable element in epilepsy is suddenness of onset, and that this is the only truly sudden disease. Other diseases in which suddenness seems to figure are only apparently so. Among these are laryngismus stridulus, spasmodic asthma, hemiplegia, etc. As distinguished from epilepsy, hysterical attacks are preceded by emotional excitement. Neuralgia, chorea, mental disturbance, are affections more or less progressive. They may be rapid in their onset, but never sudden in the sense that epilepsy is. A sudden mental derangement is always epilepsy, and therefore all recurring symptoms, whether sensory or motor, when characterized by suddenness are ominous, because suggestive of epilepsy. The more marked motor phenomena are not necessary in epilepsy in order that the more grave mental phenomena of that disease may occur. Mental degeneration and homicidal mania follow equally upon the seemingly insignificant symptoms of *petit mal* as upon the seemingly grave symptoms of *grand mal*. So far as the results go, nothing could be more complete than the minor disease.

Dr. Thomson then considered the theory, generally believed in, that epilepsy is attended by a cell-discharge or explosion. He thought that this is only apparent, and not founded on fact. For instance, a man walking rapidly, if he should have the ligamentum patellæ cut suddenly, would not only fall, but would experience a shock more serious than the cutting of the ligament, because of the sudden interruption of the organized and harmonious action of the motor-nerve centres. It could be said that whereas convulsive movements could be initiated by direct irritation of the motor ganglions either in the spine or the cortical gray matter of the brain, yet the movements in an immensely preponderating number of cases are not thus initiated, but are the consequence of sensory influences, either excitant or the reverse. Any sudden sensory impression occur-

ring during motor action might in an instant turn the previously regulated motion into a virtually powerful unregulated convulsion.

Ever since he had become satisfied that the primary lesion of epilepsy was to be found in the sensory and not in the motor department of the nervous system, and that it was one characterized by lack of nutrition and not a surplus of energy, he had studied the application of this principle to treatment. While he often used to feel discouraged with the therapeutics of epilepsy, he was now growing less so, as by perseverance in spite of the recurrence of convulsions many obstinate cases finally yielded. The first object is to improve nerve-nutrition, and this can be done in many cases by cod-liver oil. This agent also tends to prevent the impoverishment of the blood by the bromides. For this purpose next comes phosphorus. He recommended a diet of milk, eggs, fish, in the place of animal flesh. Too rapid eating should be avoided, and attention should be given to the functions of the alimentary tract. For quieting sensory excitability, he gave bromides. If there were indications of persistent cortical irritation, he employed corrosive sublimate. He used belladonna whenever there were symptoms related to the digestive tract. Chloral hydrate was sometimes useful at night. Digitalis was useful where there was pronounced vascular disturbance or symptoms connected with the genito-urinary tract. One expedient which he often used with striking results was a mustard or red-pepper pack.

Dr. L. PUTZEL thought the prodroma of epilepsy, sometimes lasting two or three days, were against the idea that it was always a sudden disease. He did not think that the paralytic attacks in *petit mal* were frequent, and when they did occur he thought that they were the result of exhaustion from prolonged convulsions. He did not think the convulsions which children had when teething, and which did not continue, were epilepsy; they were only epileptiform.

Remarks were made by Drs. W. H. DRAPER, PUTNAM JACOBI, and E. D. HUDSON.

Dr. A. D. ROCKWELL read a paper on

THE VALUE OF ELECTRICITY IN THE TREATMENT OF EPILEPSY.

If he were asked directly whether electricity was of any value in the treatment of epilepsy, he would unhesitatingly answer in the affirmative. There was a certain proportion of cases which, failing to receive more than temporary benefit from bromides, might recover when that treatment was reinforced by the judicious application of electricity. He cited one case in which there had not been a recurrence of the attacks for four years after the commencement of treatment by electricity combined with the usual therapeutics. The entire number of cases of epilepsy in which he had employed electricity since 1874 was twenty-eight. Ten had abandoned the treatment too quickly to estimate its value. In three cases in which it was given a fair trial it did not aid the bromides in controlling the disease. In eight other cases which were under observation from six weeks to nine months the good effect of the treatment was manifest in a greater or less degree. Recovery took place in two.

It was not known, nor was it claimed, that electricity used alone would cure epilepsy; but used in connection with bromides its value was unmistakable, and under its use a certain proportion of the cases would recover which otherwise would not. He employed central galvanization and general faradization. Many epileptics were benefited by the influence upon their general neurasthenic state. The systematic use of electricity made the system more tolerant of the bromides. Electricity should be used with care and judgment. Especially should the physician using it avoid interruption of current in central galvanization, which he relied upon chiefly.

Drs. FISHER and THOMSON made some remarks upon the paper.

REVIEWS AND BOOK NOTICES.

A PRACTICAL TREATISE ON THE MEDICAL AND SURGICAL USES OF ELECTRICITY. By GEORGE M. BEARD, A.M., M.D., and A. D. ROCKWELL, A.M., M.D. Fifth Edition. Pp. 30, 758, large 8vo. New York, Wm. Wood & Co., 1886.

From beginning to end this work shows a painstaking desire to set forth the claims of electricity as a therapeutic agent in medicine without exaggeration of its merits. In its pages the latest ideas are recorded, and the chapters on electro-physics, electro-physiology, and electro-diagnosis are noteworthy for their fulness, clearness, and adaptation to the wants of every-day practice. No book on the subject by an American author will rank with this volume in intrinsic value, and it is simply indispensable in the library of the thinking and reading physician. The index and glossary are very comprehensive.

W. R. D. B.

MISCELLANY.

OLEOMARGARINE LEGISLATION.—The war over oleomargarine wages vigorously, and the decision just rendered by the Supreme Court of Pennsylvania will tend to complicate the question. The Court of Appeals of New York a short time since decided that it was not constitutional to prohibit absolutely the manufacture and sale of oleomargarine, this product not being deemed unhealthy when properly manufactured. It was held proper to regulate the

sale and prevent its being offered for genuine butter, but the absolute prohibition of all manufacture and sale was held improper. The Supreme Court of Pennsylvania now takes part in the discussion and decides directly opposite to the New York court. The case involved about the same question, and the court says, "The manufacture, sale, and keeping of an article may alike be prohibited by the Legislature, if in their judgment the protection of the public from injury and fraud requires it. To deny the authority of the Legislature to do so is to attack all that is vital in the police power."

NEW JOURNALS DEVOTED TO THERAPEUTICS.—In Germany, Drs. Liebreich, Langaard, and Rabow are the editors of a new medical monthly devoted to clinical medicine and new remedies. In France, Dr. Henri Huchard will edit a medical weekly entitled the *Revue Générale de Clinique et de Thérapeutique*, the first issue of which appeared February 17. The material in these journals, consisting of original contributions, clinical lectures, annotations on new remedies, and reports of societies, promises to be of great interest and value to the profession.

NOTES AND QUERIES.

A REMARKABLE CASE OF INJURY TO THE PERINEUM.

MR. EDITOR,—On the 27th of December, 1886, I was called to see a son of Mr. J. B. H., of West Wateree. Mr. H., who came for me, told me that his son was running along after a wagon, sliding a shovel in front of him, holding the handle with his hands in front of him, when the shovel struck against a stump, and the handle was forced through "his son's guts." He found his son in a faint, and had to employ considerable force to extract the shovel-handle. He further stated that the handle punched a round hole through the pants, shirt, and drawers of his son.

I found that the handle belonged to an ordinary road- or scoop-shovel, and measured one and one-half inches in diameter, and was rounded on the end. When I reached the patient, who is about 21 years old, he was lying before a fire in apparently no pain. On inspection, I found a round hole punched, though it looked as if it had been cut, through the pants, shirt, and drawers, a little tear on the right side of the penis, an inch from the end, and a semilunar cut or tear on the anterior surface of the scrotum, being nearly on the median line, but a little to the right. On digital exploration, I found an opening clear through the scrotum, entirely as above stated, and tearing its way out under and through the perineal skin and superficial fasciæ, barely missing the external sphincter ani muscle. The hole was so large that I could easily put my thumb through it. I could detect no injury to the right testis.

I stuffed the wound with iodoform, after washing with carbolized water, and left a drainage-tube running clear through the scrotum, which was also partly filled with iodoform. The penis being also dressed with iodoform, I padded the injured parts with absorbent cotton, fixed a bandage to support the genitals, and had the patient put to bed, ordering quin. sulph., gr. xx, as a safeguard against traumatic fever.

The patient's residence being in the country, he was not seen until on the 30th inst., when, being sick, I got Dr. B. to see him for me. He found no fever, very little pus, scarcely any inflammation, and only a little soreness in the parts, the small wound on the penis giving more pain than the larger wound in the scrotum. The iodoform-treatment was continued, being injected through and around the drainage-tube while suspended in glycerin and water.

I saw him again on January 6, 1887, and found everything looking healthy, scarcely any pus or pain, and no fever. I took out the tube and ordered the iodoform-treatment to be continued, and to be injected as before carefully as long as there was any opening in the scrotum. In a few days over a month from the time he was hurt, the young man was at work.

What I consider so remarkable in this case is that, notwithstanding the wound made by the one-and-one-half-inch shovel-handle through the scrotum and perineum to the anterior edge of the external sphincter ani, there was no fever, suppuration, nor pain worth noting. I am inclined to think that the kindly healing of the wound without any trouble was due to the iodoform. I always use iodoform very freely, and have never seen any harm from it, except, when using it in a case of ulcer and fissure of the anus, I noticed, after a free use of it, there was brought on a pruritus; and I noticed this only once.

Is there on record a case like this in any respect? If there is, I would like to hear of it. I have never heard or read of any wound similar to this in its nature, cause, or way of healing.

JOHN W. CORBETT, M.D.
CAMDEN, SOUTH CAROLINA.

OFFICIAL LIST

OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U.S. ARMY FROM MARCH 13, 1887, *TO MARCH* 26, 1887.

CAPTAIN WILLIAM W. GRAY, ASSISTANT-SURGEON.—Leave of absence further extended two months. S. O. 62, A. G. O., March 17, 1887.

CAPTAIN WILLIAM F. CARTER, ASSISTANT-SURGEON.—Leave of absence extended four months, on surgeon's certificate of disability. S. O. 57, A. G. O., March 11, 1887.

FIRST-LIEUTENANT GUY L. EDIE, ASSISTANT-SURGEON.—Leave of absence extended three months. S. O. 67, A. G. O., March 23, 1887.

FIRST-LIEUTENANT JEFFERSON W. POINDEXTER, ASSISTANT-SURGEON (recently appointed).—Ordered for temporary duty at U. S. Military Academy, West Point, New York, relieving Captain Richard W. Johnson, Assistant-Surgeon, who will return to his proper station (Fort Adams, Rhode Island). S. O. 62, A. G. O., March 17, 1887.

CAPTAIN FRANK REYNOLDS, ASSISTANT-SURGEON (retired). Died March 4, 1887, at Oakland, California.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U.S. NAVY FOR THE TWO WEEKS ENDING MARCH 26, 1887.

SURGEON J. B. PARKER.—Ordered to the U.S.S. "Ossipee."

SURGEON C. A. SIEGFRIED.—Ordered to Baltimore, Maryland, on special duty.

SURGEON JOSEPH HUGG.—Placed on Retired List, March 17, 1887.

ASSISTANT-SURGEON F. J. B. CORDEIRO.—Detached from Navy-Yard, Boston, and placed on waiting orders.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U.S. MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDING MARCH 26, 1887.

BAILHACHE, P. H., SURGEON.—To proceed to Mobile, Alabama, Pensacola, Florida, Ship Island, Mississippi, and New Orleans, Louisiana, as inspector, March 14, 1887.

LONG, W. H., SURGEON.—Granted leave of absence for seven days, March 16, 1887.

GOLDSBOROUGH, C. B., SURGEON.—Granted leave of absence for thirty days, March 14, 1887.

DEVAN, S. C., PASSED ASSISTANT-SURGEON.—To proceed to Tacoma, Washington Territory, as inspector, March 19, 1887.

LONG, W. H., SURGEON.—Leave of absence extended five days, March 23, 1887.

URQUHART, F. M., PASSED ASSISTANT-SURGEON.—Relieved from duty at Norfolk, Virginia; ordered to Washington, D.C., special duty, March 22, 1887.

PETTUS, W. J., ASSISTANT-SURGEON.—When relieved by Assistant-Surgeon Guitéras, to remain at Charleston, South Carolina, "waiting orders," March 24, 1887.

PHILADELPHIA, APRIL 16, 1887.

ORIGINAL LECTURES.

CLINICAL LECTURE

ON A CASE OF COMMINUTED FRACTURE OF THE ASTRAGALUS, WITH EXCISION OF FRAGMENTS; ON RESECTION OF ELBOW-JOINT; AND ON THE VALUE OF ANTISEPTIC DRESSINGS.

Delivered at the Pennsylvania Hospital, Philadelphia, March 30, 1887,

BY THOMAS G. MORTON, M.D.,

One of the Attending Surgeons to the Pennsylvania Hospital, and also to the Orthopædic Hospital, etc.

GENTLEMEN,—The case to which I now ask your attention is one of unusual interest and importance,—interesting on account of the character of the injury, important as a demonstration of the advance in clinical surgery as a direct result of the recent application of the principles of the Listerian system to the treatment of wounds. By its aid operations may now be successfully performed which by former methods were entirely inadmissible. Of the truth of this statement this case is an illustration.

Charles B., 54 years of age, a house-painter by occupation, fell from a scaffolding on the 23d of this month, and was brought here immediately after the accident occurred. He does not know what part of his body struck the ground. Upon admission he had a weak pulse, and his temperature was only 96½°. He complained of great pain in the back and legs; he could not walk, but he had power of motion and sensation in both lower extremities. He had a number of contusions, and his right ankle was swollen.

The treatment during the first twenty-four hours consisted in applications of dry heat and the administration of stimulants and morphine to relieve pain and restlessness. On the following day a more careful examination revealed what was apparently a dislocation of one of the tarsal bones of the right foot forward, so that it was quite movable under the skin of the instep. It was subsequently found that this was the anterior portion or head of the astragalus, which had been broken off by a vertical line of fracture from the remaining portion of the bone, and separated from its ligamentous attachments. The ankle-joint was so disorganized that the toes were extremely everted. Crepitus could be obtained, apparently due to fracture of one or both malleoli. The left ankle was also swollen and painful on motion, but there were no signs of fracture. His general condition having improved, I made an incision on the outside of the foot, following closely the line of incision for the excision of the cuboid bone, as in the case I showed you some weeks ago. Upon opening the joint I removed the entire astragalus in a number of separate fragments. The wound was thoroughly cleaned, a drainage-tube passed through the joint and out of an opening made over the instep on the inner side, the edges of the wound were drawn together with the interrupted suture, and an antiseptic dressing of Lister gauze and iodoform applied. Both feet were placed in fracture-boxes and suspended from a frame above the bed.

On the 29th the wound was dressed (five days after the operation). There had been no suppuration whatever. There was no redness and no swelling around the wound. His pulse, respiration, and temperature record was as follows:

March 24, A.M...	.....	...	.....	P.M...	118	20	100°
March 25, A.M...	120	18	98½°	P.M...	120	22	99°
March 26, A.M...	104	20	98½°	P.M...	112	18	98 2/10°
March 27, A.M...	120	22	98½°	P.M...	112	20	99°
March 28, A.M...	118	20	97½°	P.M...	116	24	98 2/10°
March 29, A.M...	112	18	98½°	P.M...	104	22	98°
March 30, A.M...	112	22	97°				

His temperature was 100° on the afternoon of the operation, partly due, perhaps, to the administration of the anæsthetic; since then it has been normal. He has had good union except at the point where the drainage-tube is, and this we will remove to-day. The rubber tube was inserted because I thought that we might have considerable serous oozing. It is impossible to tell beforehand whether there will be much or little. Had I known that there would be no more effusion than we have here, I would have employed the drainage of chromicized catgut, which would have been absorbed without interrupting the healing of the wound.

RESECTION OF ELBOW-JOINT.

This man, 28 years of age, suffered an injury of his right elbow, by having it caught between the bumpers when coupling cars,

a month ago. There was fracture of the internal condyle of the humerus and of the ulna, and great contusion of the parts. The wound was treated with irrigation. Following the injury the fracture became compound, after which we removed some fragments of bone. At that time his temperature reached 101°, but has since declined to normal. As he seems in good condition, with a normal temperature, I will now do a resection of the elbow-joint.

In making a resection of this joint we need particularly to bear in mind the course and location of the ulnar nerve and brachial artery. The incision is made on the posterior aspect of the joint, and I will now remove a portion of the humerus and the olecranon, and, if necessary, part of the head of the radius.

The limb is first shaved, washed with turpentine, and then with corrosive sublimate (one to two thousand). An Esmarch bandage is applied, and rubber tubing fastened around the middle of the arm, and towels wet with sublimate solution are placed on each side of the field of operation. I find necrosis of part of the ulna and humerus requiring removal with a chain-saw, and I will also shave off the head of the radius. This is really a case in which amputation would have been preferable to resection; but the patient objected to it so strongly that we will try to save the limb.

After removing the bone, the inside of the cavity is thoroughly scraped out with a curette. It is very important to get rid of all this granulating tissue, which acts as a source of irritation. The sinus is now converted into the condition of a simple incised wound. We now remove the rubber tourniquet and find that there is very little bleeding. A drainage-tube is inserted, and the wound closed with sutures and dressed antiseptically. The secretions of the wound, which are necessarily aseptic, will come through the gauze and be absorbed by the cotton.

REAMPUTATION FOR PAINFUL STUMP.

The next case is quite an interesting one. He has been the subject of several operations since his admission into the hospital, eighteen months ago. An amputation of the upper third of the leg for an injury was followed by painful stump. Resection of the external branch of the popliteal was performed, and he had relief from suffering for a time, but only for a time, for the neuralgic pains gradually returned and became as severe as before. We conclude in these cases that some filaments or small inosculating branches have escaped division and gradually restored the nerve-functions, or the ends of the nerve become reunited by fibrous tissue. At the Orthopædic Hospital of this city we have tried a number of expedients to prevent reunion of the ends of the nerve after section, bringing them in diverse directions in neighboring muscles or doubling them backward upon themselves and fastening the ends alongside of the nerve-trunks. But quite often, in spite of all our efforts, they reunite and restore the channel of nerve-conduction. In this patient I also subsequently resected the internal popliteal, but with a like result. You can see the scars of each incision. As he now suffers again from neuralgia of the stump, I will proceed to do a Teale amputation just above the knee.

It is probably sometimes the case that neuralgia affecting a stump after amputation may have a central origin, but in others some local cause like a bulbous enlargement of the ends of the nerves may be the explanation of the symptoms. In either case an operation would be justifiable. The dressings are applied after the operation in the same manner as the preceding cases, substituting chromicized catgut drain for the rubber tube.

RESULTS FROM ANTISEPTIC DRESSINGS DURING FIVE MONTHS' SERVICE IN THE MEN'S SURGICAL WARDS.

The following is the statistical report of my recent term of service—from September 1, 1886, to January 29, 1887, inclusive.

Two hundred and nineteen surgical cases were admitted into my ward. Of this number, two hundred and eleven were cured, one was improved, four remained convalescent, and three died. Of the three fatal cases, one was due to pleuropneumonia following a lung-wound caused by fractured ribs; one was from a rupture of the intestine following an injury (the patient was in a dying condition when admitted); and one was from hemorrhage into the pleural cavity following a gunshot-wound of abdomen and chest.

Of the two hundred and eleven cases which recovered, fifty were simple and

eighteen were compound fractures;* six were crushes involving the feet; five were crushes involving the hand; four were compound fractures of the skull; two involved the inferior maxilla; one involved the wrist-joint; and one presented a compound dislocation of the knee.

There were twenty-nine lacerated, incised, punctured, and gunshot wounds. One stab involved the brachial artery, with complete division of the biceps muscle; one opened the ankle-joint; one opened the thorax; and one opened the abdominal cavity.

There were sixty-seven serious surgical operations performed, with but a single death, and this followed a gunshot-wound of the abdomen, to which I shall again refer.

There were also an enormous number of minor operations done in the casualty ward. These cases were promptly sent to their homes, and, for obvious reasons, have not been included in these tables. As far as I know, no harm befell any of them.

No outbreak of cellulitis, phlebitis, abscess, erysipelas, tetanus, septicæmia, or pyæmia followed any operation, and there was no secondary hemorrhage. There was one case of consecutive hemorrhage some few hours after an operation for perineal section.

In one case of very extensive scalp-wounds, facial erysipelas developed eight hours after the patient, who was a drunkard, was admitted; but the wounds united by primary intention.

I may here state that cases of erysipelas were constantly treated in the medical wards (which are directly between the two surgical wards) during the entire service, without giving us any concern.

Among the operations which antisepsis made it justifiable for me to perform, I may refer to—

1. The suturing of the broken fragments of a patella for the first time with catgut in this hospital,—indeed, for the first time, I believe, in this country.

2. In a case of double and excessive talipes equino-varus, excision of the cuboid bone in each foot for the first time in my experience, and for the first time in the hospital.

3. The first radical operation in the hospital for the removal of the glands involved in bubo was recently performed, and on several occasions successfully repeated.

4. My first abdominal section for gunshot-wound in this hospital I performed quite recently.

During my late term of service I resected the long bones of upper and lower extremities. Union of the radius and ulna occurred with a single dressing. The major amputations (except in one instance, where I used a rubber drainage-tube) were dressed only once, and that at the time of the operation. In each instance the original dressing was removed on the twenty-first day or later, in the presence of the class, and in every case the result showed a perfectly united, solid, sound stump. Catgut drain was in these cases always used, with the single exception referred to.

In two cases which required trephining for compound depressed fractures of the skull, no symptoms followed these operations. In one case the patient was up and about the ward on the fourth day; the other on the third day. In both cases the primary dressing was not removed until the end of the third week, and no further dressing was applied.

In a comminuted fracture of the patella, after fully opening the joint by a vertical incision, the fragments were drilled in three places and securely held in close apposition by catgut; in this case apparently good bone-union has taken place.

In another case the knee-joint was entirely exposed by a fall, which ruptured the old inflammatory adhesions that had been thrown out in nature's attempt to unite by new tissue a quadriceps ruptured more than a year ago. The condyles and head of the tibia were exposed, the lateral and crucial ligaments were torn, the wound of the soft parts of the joint was so extensive that the leg was held only by a band of tissue posteriorly; the vessels and nerves were preserved intact. Twenty interrupted catgut sutures and one dressing were all that was required, and a perfect recovery followed.

The main arteries of limbs and elsewhere were tied, and uniformly with but a single dressing and no pus.

Large scrofulous and simple abscesses were freely opened, and, after being curetted, healed at once as in ordinary incised wounds.

* The fact that simple fractures and subcutaneous tenotomy, as the rule, repair promptly and without causing any septic conditions should be noted.

The last time I operated upon a case of scrofulous abscess was seventeen days ago. It occupied the outer chest-wall on the left side, and, after it was opened by an incision twelve inches in length, three ribs were found to be involved in superficial necrosis. The contents of the abscess were about ten ounces, and the walls were covered by a pyogenic membrane, which was completely removed with the curette. The ribs were also curetted until they freely bled. The cavity, having been thoroughly cleansed, was, after placing at the lower angle a small rubber drain, brought together by a large number of catgut sutures. The chest-movements were partially controlled by the laced corset similar to that used for fractured ribs.

This case was dressed again on the seventh day, the drain was removed, and there was perfect union throughout. It has not required dressing since.

Let me formulate the following conclusions from this five months' trial of antiseptic methods:

By the use of antisepsis we have been enabled to secure absolute cleanliness in the dressing of wounds.

By this means we shorten the wound-healing period by securing primary union, and can thus protect the patient from the dangers incident to suppuration, and so get rid of cellulitis, phlebitis, abscess, septicæmia, pyæmia, and secondary hemorrhage.

We also materially lessen the chances of the occurrence of erysipelas and tetanus.

By the infrequency of renewal of surgical dressings, pain, so frequent in handling wounds, is materially lessened, if not entirely avoided.

We are also able to adopt a conservative course in many instances, and limbs and joints are saved which, under other treatment, would of necessity be sacrificed.

We have abolished those scourges which so long have infested surgical wards, the sources of "hospitalism," so that we at last have succeeded in accomplishing that which has always been the aim of surgery. The mortality-rate has been remarkably reduced by the introduction of the antiseptic method, and I feel warranted in declaring that where it is practised deaths in surgical wards should occur only in cases commonly recognized as "unavoidably fatal."

ORIGINAL ADDRESS.

MEDICAL TEACHING, PAST AND PRESENT.

Abstract of an Oration delivered before the Alumni Association of the Medico-Chirurgical College of Philadelphia, Thursday, April 7, 1887,

BY DUDLEY S. REYNOLDS, A.M., M.D.,

Louisville, Kentucky.

WHEN anatomy was studied in a few of its meagre outlines merely, and for the most part in secret, there came forth a man named Monro, in the great city of Edinburgh, where Benjamin Rush, Ephraim McDowell, Walter Brashear, David Hosack, and Benjamin Dudley received their first medical training, and with the force of great eloquence and a thorough mastery of what appeared, at that time, all of the details of anatomy, succeeded in investing the dry bones of the skeleton with a fascination but little less forcible than that with which the immortal Shakespeare has clothed the cowardly assassin of Duncan, Scotland's famous king. Monro was so great in his style and manner of teaching that the medical school at Edinburgh became for the time the leading medical institution of the world. From that day to the present the study of anatomy has been rendered simple and easy.

An ambitious physician of that time, jealous of Monro's great success and reputation as a teacher, built a hall in Edinburgh and established therein a museum of anatomy. To his amphitheatre he invited the students and practitioners of medicine to hear him lecture and witness his demonstrations. He rattled the dry bones before his audience with such energy and spoke with such eloquence that he soon robbed the great university of all its students at the time of the usual lectures on anatomy. This man's boldness in exhibiting the skeleton, and even the cadaver itself, for purposes of demonstration aroused great excitement, but the earnestness with which he prosecuted his work finally won for him that success he so much deserved.

This may be said truly to have been the very beginning of illustrative methods in medical teaching. It was a long time, however, before other branches of the curriculum advanced beyond the prevailing theories of a few leading men.

On the 9th of July, 1790, Dr. Benjamin

Rush stood in the hall of the College of Physicians in this city and delivered a eulogium upon the life and character of William Cullen, the author of a new system of medicine. Said Dr. Rush, "This illustrious physician was the preceptor of many of us; he was, moreover, a distinguished citizen of the republic of medicine, and a benefactor of mankind; and although, like the sun, he shone in a distant hemisphere, yet many of the rays of his knowledge have fallen upon this quarter of the globe. Dr. Cullen possessed a great and original genius in discerning the relation of distant truths by the shortest train of intermediate propositions. His imagination surveyed all nature at a glance, and, like a camera obscura, seemed to produce in his mind a picture of the whole visible creation. His knowledge was minute in every branch of medicine; he was a great anatomist and an ingenious physiologist; he enlarged the boundaries and established the utility of chemistry; he stripped materia medica of most of the errors that had been accumulating in it for two thousand years, and reduced it to a simple and practical science."

At the time Cullen made his appearance as a teacher, the doctrines of Boerhaave were universally prevalent. Boerhaave believed that all diseases depended chiefly on the presence of certain acrid particles in the fluids of the body, and in a departure of these, in point of consistency, from the natural state.

Says Dr. Rush, "Cullen's first object was to expose the errors of this pathology, and to teach the public to seek the causes of disease in the solids."

Cullen's theories concerning the nervous system so impressed his eulogist that he boldly proclaimed, "No man would ever unravel the operations and the whole nature of the nervous system without being forced to acknowledge that the foundation of his successful inquiries was laid by the discoveries of Cullen."

The "pathies" and "isms" arose, and flourished for the edification of imaginative people. The few facts pertaining to every branch of medical education excepting anatomy and botany were so scattered as to defy every attempt at establishing principles, until finally Billings came, and the new pathology of Simon opened up new fields for speculation and experiment.

Dissection became a recognized part of the curriculum, and was openly announced as part of the requirements in all the best schools.

John Hunter's great thirst for experimental knowledge had wellnigh taken hold of the world when Jenner, in 1798, came as the apostle of a new creed, based upon the experiences of the humble dairymaids. Vaccination as a protective measure against the smallpox remains an unexplained fact.

Presently instruments of precision began to be employed; vivisections of inferior animals were made, and the science of biology began to receive fresh attention. The humoral pathology, homœopathy, Thompsonianism, and all the "isms" and "pathies" paled into so many dim shadows over the fields of former conquests.

The medical student now, instead of sitting patiently by the hour listening to the beautiful sophistry with which individual theories and hypotheses concerning the nature and character of disease were supported, has at length come to the point where demonstration of the theories and illustrations of the methods of practice are demanded.

The growth of medical education, it may be said, has been slow. Twenty-five years ago there were, indeed, but few schools in the country where clinical and laboratory instruction formed anything like a prominent feature of the curriculum. The result of these practical methods of inquiry, and of the substitution of the few demonstrated facts applicable to the study of disease, has been wonderful. A great and new science of pathology is now established upon the ruins of Cullen's popular theory.

The great Pancoast comes no more to stand before you, with burning lips and irresistible arguments, to convince you of the superiority of his method of treating wounds; in his stead, the gifted son invites you now to the dispensary and to the clinic-rooms, that you may see for yourselves the masterly touch of his cunning hand in the adjustment of fractured bones, or witness his skilful methods of stanching the flow of the crimson tide in wounded arteries. You are not asked to believe upon the mere statement of your professor of chemistry, whose beautiful experiment of the consuming powers of oxygen and the frigid powers of carbonic acid gas are, upon the one hand, the life-giving force in

the atmosphere we breathe, and, on the other, the death-dealing force in the dark recesses of subterranean caverns. He does not content himself with telling you that carbonic acid gas is evolved from the mixture of sulphuric acid and carbonate of lime, but proceeds at once to the demonstration, and with the magical process of his art he compels every member of his class to become practically familiar.

In the pathological laboratory, which is an institution of comparatively recent device and origin, you now study in the dead subject the nature and extent of those changes wrought by disease.

Experimental research has at length brought to light the startling fact that nearly all of our diseases, and especially the contagia, arise from specific micro-organisms, which, although their life-histories have been studied with great minuteness of detail, cannot with certainty be classified as animal or vegetable in their nature. A minute rod-shaped body, called by its discoverer, Dr. Robert Koch, the chief of the great "Gesundheitsamt" of the Prussian empire, the *bacillus tuberculosis*, is now universally recognized as the cause of all tuberculous processes in man and the inferior animals. It has likewise been discovered by experiment that this bacillus is wafted in the air, that it grows in lymph by preference, and when inoculated or injected beneath the skin it passes into the blood-current, and there seizes upon the germinal matter or sarcode of the white blood-cell, arresting the cell instantly in its course, causing it to assume enormous dimensions, interfering in that way by obstructing the blood-stream, and presently, when it ruptures, to discharge its myriads of spore-cells to attack in like manner contiguous leucocytes, until the current of blood in that tube is arrested. This of course speedily brings on those changes characterized by heat, pain, redness, and swelling.

Now, when the bacillus is breathed into the air-passages, if the whole of the respiratory membrane be sound upon its surface the bacillus will not grow, but will find a temporary lodgement in the mucus, and presently be snuffed up and hawked out, or coughed up and expectorated. If, however, these bacilli or their spore-cells lodge upon an abraded surface, where they gain ready access to the lymph-tubes, they colonize and grow there, and by slow invasion the whole lymphatic system may be destroyed. With these facts, we are at once prepared to appreciate both the means and the reason why tuberculous disease generally invades the respiratory organs first, and why tuberculosis as an inheritance generally proves fatal to the infant.

The specific cause of suppuration in wounds has recently been brought to light in the discovery of microbes, which collect in groups, and which, when assembled in large numbers, present a golden-yellow tint. This is called the "staphylococcus aureus," and to some recent experimental researches of Professor Cornil, of Paris, and Prudden, of New York, we are indebted for the demonstration that suppuration in wounds is invariably the result of the presence of this microbe.

Scarcely less brilliant have been the discoveries in chemistry and physiology. Merck, of Darmstadt, has at last succeeded in producing, by synthesis, many of our most valued therapeutical agents, and in 1879 he brought forth a new product by this agency, which is known and prized by every ophthalmic surgeon in the world.

In testing the refraction of the human eye it is necessary to suspend the focussing power in order to secure accurate results. For this purpose the sulphate of atropine, long in universal use, required in many cases from three to five days' constant use of the drug to bring on complete suspension of the accommodation, and then from twelve to fourteen days were required for the patient to recover fully from its effects. The hydrobromate of homatropine, made by the synthetical method of Merck, whilst at the same time free from toxical effects, is speedy and more uniformly efficient in suspending the accommodation than any drug hitherto employed for that purpose, complete suspension now being possible within the brief space of an hour and a half, and all signs of its effects disappearing uniformly within thirty hours. It is likewise powerful in the relief of pain, and may be instilled into the eyes of children with perfect impunity in solutions of the same strength as are used for adults.

Further, the manufacturing chemists now separate the active principle from the crude drug, and prepare our most potent medicines in granules, triturates, and compressed tablets, all divided for conveni-

ent use. With the exact knowledge now conveyed to the student of medicine in the clinic-rooms and laboratories of our colleges, the minutiæ of scientific processes must be mastered, and the graduate, armed with these powerful weapons of so many exact sciences, goes forth to practise in communities where general intelligence makes closer discrimination as to the qualifications of the medical practitioner than were made in former years. The aid of legislation has in recent years come forth as a thunderbolt from the people against empiricism and quackery.

In this great commonwealth your legislative authority has wisely ordered that no man shall practise without a diploma duly signed by one of the lawfully-constituted faculties of instruction in a regularly-established medical college in Pennsylvania. In the old State of Virginia, and in some other States, diplomas are no longer recognized as licenses to practise medicine, but are demanded as preliminary to the examination of the holder who is an applicant to practise in such States.

Now, with these powerful agencies of the law encouraging the efforts of able and earnest teachers in the regularly-established medical colleges of this country, there is no danger that too many people will qualify to practise the art of healing. There are, of course, many commercial schools throughout the country pretending to give instruction in medicine. These are found in almost every State, and the holders of their diplomas may be found in our cities, driving the street-cars, washing bottles in suburban drug-stores, and in many cases pointing horse-shoe nails or gently guiding the brush of paint over cold brick walls of our houses. With the rapidly-growing population of this country we have no excess of medical colleges, and there is, as Webster said to the student of law, always plenty of room in the higher walks of the profession. In the lower grades you shall gradually witness the decay that ignorance always suffers in the presence of scientific research.

Do not understand me to say that the practice of medicine itself shall ever reach the dignified plane of an exact science. The uncertain tenure of life, and the varying degrees with which the vital forces operate in the economy, taken together with the varying conditions in which they operate, make it impossible; yet, by the aid of experimental study, the present generation has witnessed the discovery of the cause of nearly all the infectious contagia; and in their treatment the ounce of prevention may now wisely be ordered. For most of them the pound of cure has not yet been isolated. May we not hope that some one of these young gentlemen just admitted to the ranks of the profession this evening shall achieve this great goal for which we are all striving? May we not hope that, great as have been the giants in the medical profession in this metropolis, greater genius is now being bent into the same channels, and that the march towards perfection shall not be abandoned by a single one among them until the devotees of medicine shall be able to establish a universal science?

ORIGINAL COMMUNICATIONS.

ARTERITIS COMPLICATING TYPHOID FEVER.

BY L. HARRISON METTLER, A.M., M.D.

IN a previous paper* I endeavored to show that an endarteritis of more or less severity is primarily the cause of the gangrene which occasionally determines the unfavorable result of an attack of typhoid fever. The possibility of the occurrence of this grave accident renders not unworthy a brief consideration of its diagnosis and treatment. The literature upon arteritis is far from being commensurate with the importance of the subject, a fact which is probably due to the great obscurity which overhangs the pathology of this disease. Of arteritis complicating typhoid fever the study has been still more unsatisfactory, and the anxious practitioner may look in vain through many of our standard authorities for suggestions as to the symptoms and therapy of an accident which may prove one of the most disastrous that he will encounter during the whole course of the fever. He will realize the feelings of the countryman of whom the poet says,—

> "Rusticus expectat dum defluat amnis; at ille
> Labitur et labetur."

Arteritis, general or localized, is believed by many to be not an infrequent

* Vide Philadelphia Medical Times, No. 502, vol. xvii.

companion of typhoid. It becomes therefore a matter of the highest moment to recognize it, if possible, *early* in the course of the fever, lest it may be the cause of a thrombus within the vessel itself, and thus of a secondary gangrene.

However it may be produced, arteritis with typhoid fever presents no symptoms *per se* different from those of any other kind of arteritis. The morbid anatomy, as proved by actual demonstration, is always the same in all forms. We find always the same roughening of the intima, the same engorgement of the walls, the same diminished elasticity, the same embryonic infiltration of the three tunics. There is a close intimacy between the blood and the blood-vessels, so that any deviation from the normal in the condition of the former will more or less affect the condition of the latter. The poisonous condition of the blood is the cause of the intima and media being the frequent origin of the inflammatory process, but it sometimes happens that a periarteritis occurs in typhoid fever with but a slight implication of the inner coats. Owing to the ramification of the vasa vasorum in the outer coats (appearing only in the inner coat when they are inflamed as in conjunctivitis), an inflammation of the external tunics will be sthenic and conservative in character, while in the internal tunic it will have more of a tendency to disorganize and to destroy.

Arteritis, when it occurs, manifests its first symptoms at about the latter part of the third week of the fever,—about the beginning of convalescence. Just when the patient's hopes of a speedy return to health are beginning to brighten, and everything is apparently progressing in a most happy manner, a quick, sharp, stinging pain is suddenly felt along the course of the affected vessel. In some instances, in which the inflammation is not so violent and so acute, this pain begins even earlier, and is then of a dull, aching character, gradually becoming more intolerable with the daily advance of the affection. In a case in which it occurred suddenly the patient likened it to the "stretching or tearing of the nerves of the limb." Appearing thus, as it were, spontaneously, it is increased by every movement on the part of the patient,—by walking, by simply maintaining the upright position, and especially by external pressure of any sort. By means of the last fact the site of the inflammatory process, when it is localized, can be readily determined by pressing with the fingers of the two hands over the artery, as in the case of the femoral or brachial, and along the sides, as in the case of the posterior tibial. As soon as the point of special inflammation is touched, the patient will scream with the intense agony. According to Legroux, the pain becomes intense only when the perivascular tissue is also inflamed. The severity of the pain is doubtless increased where there is also periarteritis, for it is in the adventitia that the blood-vessels and nerves terminate, whereas in the case of an endarteritis this pain is produced chiefly by the swelling and pressure of the tunics involved.

Along with this pain, which is in reality the only positive symptom of this obscure affection, there is violent throbbing, often felt in parts of the body situated at a considerable distance from the inflamed artery. This is due to the impaired elasticity of the arterial walls. Finally, there is a general weakening of the pulse-beat, which at length becomes hard and wiry in character, all due to the pathological condition of the walls of the vessel. Fever and general distress accompany these symptoms, as in other forms of inflammation. Up to this point the vessel may have still remained permeable, though its calibre may have been much diminished by the swelling of the coats. For, as Berard long ago showed, arteritis is not incompatible with the permeability of the vessel inflamed.

There are a few other symptoms, of variable degrees of certainty, however, which may sometimes be detected even before the more disastrous result of complete obliteration has taken place. Owing to the diminished blood-supply, there will be a slight lowering of the temperature in the parts, ofttimes as much as several tenths of a degree being detected by a delicate surface-thermometer. The skin assumes not unfrequently a bluish or violaceous hue, while its sensitiveness is considerably heightened. Sometimes it feels as though ants were crawling over it ("fourmillements"). Swelling, due to a slight œdematous condition of the limb, may appear. All of these latter signs are of far less significance than the pain, which of itself is almost pathognomonic of arteritis, and is readily differentiated from a neuralgia of

the neighboring nerve with which it is at all likely to be confounded, by the suddenness of its onset and its persistency after it has once announced itself. Furthermore, in neuralgia there would not be the diminished pulse and temperature, as well as the constitutional disorder, which accompany arteritis. Phlebitis and lymphangitis are easily differentiated by their production of a superficial redness in the part.

If now a clot has formed and the vessel has become permanently occluded, many of these symptoms—such as, for instance, the darkening of the skin, the œdematous swelling, the tingling of the nerves—will become still more pronounced, finally ending in a profound discoloration, numbness, complete loss of sensation, coldness, and not infrequently paralysis. But in addition to these we have two very distinct symptoms which foretell unmistakably the near approach of gangrene, even before the more superficial signs of the gangrene itself have become at all visible. The first is the complete cessation of all pulse-beat in the artery below the seat of the obstruction. The second is the sensation to the finger of a hard, irresistible, non-elastic cord produced by the occluded artery. Immediately after the appearance of these two signs, all the usual signs of gangrene begin to make themselves manifest. Blebs begin to arise on the surface, and either dry up or assume the form of pustules. Dark patches make their appearance, and, enlarging and uniting, gradually envelop the entire extremity below the point of obstruction. The part begins to dry up and mummify, or to assume the appearance of moist gangrene if the vein as well as the artery be involved. The swelling increases. Upon puncturing the skin, a peculiar yellowish or reddish fluid, of a disgusting odor, makes its appearance, exuding through the wound. So the mortification proceeds, until at length the line of demarcation becomes established, and the sphacelus is ready to be removed through the agency of nature or by the art of the surgeon.

In the treatment of arteritis complicating typhoid fever there are three special indications to be observed. The first is to remove, if possible, the exciting cause; the second, to allay the inflammation; the third, to prevent the formation of blood-clots.

With regard to the cause of typhoid arteritis, I have already stated that I believe it is to be found in the septic condition of the blood. According to Klebs, Eberth, Letzerich, Wernich, and others, there is a specific germ, the *bacillus typhosus*, which somehow produces such an alteration in that fluid as to render it more coagulable and irritant to the vascular walls. To this same condition of the blood, Estlander, Fernet (who reports a remarkable case occurring in a woman), Raynaud, Sigerson, and Duchenne attribute the faulty innervation of the arterial coats, frequently producing a vaso-motor spasm of more or less duration in the arteries, and consequently a gangrenous tendency in the distal parts of the extremities. Now, if it be true that these bacilli which enter the system through the respiratory and alimentary tracts are the cause of the poisonous condition of the blood, it is reasonable to suppose that to destroy them before they have migrated to any extent from these tracts into the general circulation is the most positive way of guarding against the arteritis directly dependent upon this deteriorated condition of the blood. To destroy these germs and to antagonize their injurious effects upon the circulation have of late stimulated to the highest exertion the energies of our ablest therapeutists. Antiseptics of all sorts have been brought into the field of experimental investigation, but so far the success has been unsatisfactory. There is the treatment by carbolic acid and iodine (the so-called German specific, and of which we have the most favorable reports), by chlorine, quinine, mercury, salicylic acid, resorcin, etc., none of which save the first offers anything like a satisfactory result. Indeed, judging from the results of antiseptic treatment, we are sometimes almost tempted to believe that perhaps, after all, the bacilli have nothing whatever to do with typhoid fever. Yet, what the pathologist tells us as to the results of his investigations, this is the proper line of investigation for the discovery of the radical cure of the disease. Perhaps the fault lies largely in the insufficiency of our experience and number of instances in which the antiseptic treatment alone was used to the total exclusion of other remedies, which may have had the effect of modifying the results. As soon as we shall have learned of an effectual antiseptic treatment for typhoid fever,

we shall have learned *par avance* the best prophylactic treatment for the complicating arteritis and its disastrous results.

Again, granting that the cause of the arteritis is the deterioration of the blood by an organized germ, would the use of antiseptics be of any avail in checking it when already in progress? Certainly not, so far as they are employed simply as antiseptics. As antipyretics some of them may be employed with the greatest advantage—as, for instance, mercury in the form of calomel, quinine, salicylic acid, and resorcin—as soon as the secondary fever resulting from the arterial inflammation shall have occurred, which is usually at about the beginning of convalescence. About this time, however, the general improvement in the condition of the patient indicates that the bacilli and their immediate influence upon the blood have been overcome. The damage to the arterial walls has already been done, and our attention must now be directed to follow out the last two indications of the treatment.

Any remedies employed during the course of typhoid fever to lower the temperature, to control the secretions, and otherwise to modify the fever itself will have the same salutary effect upon the course of a latent arteritis that may be present. In all probability, this is the reason why an obliterating arteritis in the larger vessels is comparatively so rare a complication, while in the more minute arteries it is so much more frequent, as is seen in its frequent after-effects, such as the hemorrhagic infarcts of the various viscera and the almost constant muscular degenerations. With the aid of the antiphlogistic treatment employed in the typhoid fever, the larger vessels are enabled by their greater strength and vitality to resist the tendencies to become inflamed.

When an arteritis of any of the larger vessels may have been happily detected early, most prompt and decisive treatment will be necessary to the hope of preventing the formation of a thrombus and mortification of the part. Though an attack of local arteritis may end occasionally in resolution, the fibrinous deposit being absorbed by the aid of appropriate remedies, by far the majority of the attacks end in complete obliteration of the lumen of the vessel. Nevertheless, we should never despair, but at once employ measures to bring about a resolution if possible. A free action of the emunctories should be promoted by the use of purgatives, diuretics, and diaphoretics. For this purpose we may use the oleaginous purgatives, castor oil, calomel, antimonials combined with refrigerant salts (nitrate and acetate of potash), acid drinks, etc. The vascular excitement should be lowered by the use of aconite root, veratrum viride, or hyoscyamus in camphor mixture. If the patient can bear it, colchicum, antimony, and mercury with calomel may be employed to assist the absorption of the fibrinous concretions. Pain should be relieved by opium internally or externally, preferably by morphia hypodermatically.

In diseases of the vascular system we must not rely wholly upon medicines. The diet should be light yet nutritious, consisting chiefly of the farinaceous foods. Chomel and others regard the adynamic form of typhoid fever as the most favorable to the development of the gangrenous complications. Hence the vital powers should be maintained by the judicious use of tonics. Stimulants should not be used unless they are urgently demanded by the rapid sinking of the patient.

The local treatment of arteritis, when the site of the inflammation has been positively established, is quite as important as the systemic. The limb should be elevated, leeches applied, hot stupes placed over the course of the artery, or, if more agreeable to the sufferer, cold-water dressings, poultices of chamomile-flowers, or decoctions of poppy-heads, to quiet the inflammatory action and to relieve the pain. The patient's mind and body should be kept as tranquil as possible. In this way there is a bare chance of averting the threatened gangrene. But so obscure are the signs of arteritis itself that by the time its diagnosis is fully established obliteration has already taken place and the gangrenous spots have already begun to appear.

Now the most important duty of the physician is to support the patient and to stimulate the circulation by means of alcohol and digitalis. The peripheral circulation should be awakened, if possible, by the alternate application of heat and cold. As suggested by Dr. Keen, the constant-current battery may be sometimes advantageously used for the same purpose. If the gangrene still continues to advance and all our efforts to restore

the circulation have been futile, all we can then do is to make numerous incisions into the mortified tissue, cover it with laudanum dressings, dust over it absorbing powders, aromatics, and antiseptics, and watch for the appearance of the line of demarcation. The amputation, which is the *dernier ressort*, is rather a surgical than a medical question.

1938 North Broad Street, Philadelphia.

A CASE OF TIC DOULOUREUX OF TWELVE YEARS' STANDING TREATED BY LARGE DOSES OF THE SALICYLATES WITH MARKED SUCCESS.

Read before the Philadelphia Neurological Society, February 28, 1887,

BY FRANCIS X. DERCUM, M.D.,

Instructor in Nervous Diseases, University of Pennsylvania.

ON November 30, 1886, the writer was summoned to attend Mrs. K., aged 52 years. She was a German by birth, of good physique, and had been the mother of a number of healthy children. She told me at once that she was a sufferer from tic douloureux. It needed no exhaustive investigation to prove that her statement was unfortunately true. As she spoke she was constantly interrupted by frightful paroxysms of pain. She moved her jaws as little as possible, and her words were uttered so cautiously as at times to be indistinct. She gave me her history with great difficulty and at the expense of much suffering. Twelve years ago, while apparently in good health, she was suddenly attacked by pains in the right side of the face. These gradually increased in intensity. Previous to the onset she had had no illness whatever, and she had not as yet entered upon the menopause. All of her functions, as far as I could ascertain, had been normal. She herself attributed her affection to an attack of cold.

Her suffering had been practically continuous. The paroxysms had varied at times both in frequency and severity. Sometimes they occurred many times a minute, and again but four or five times an hour. When their intensity was at its greatest height, she felt frightful darting pains, which culminated—to use her own expression—as though her face were being rent to pieces, or as though it were bursting from an explosion. When the pains were comparatively mild, they were simply shooting or darting in character. She was always worse in cold, damp, or stormy weather, and suffered much less when the weather was mild and clear.

A close examination revealed the fact that the nerve-distribution most affected was that of the superior maxillary. The inferior maxillary was also decidedly affected, but the ophthalmic division did not seem to be affected at all. The cheek, especially about the infra-orbital and malar regions, was excessively hyperæsthetic. A slight touch was sufficient to provoke a spasm of pain. The same was true, though to a less extent, of the gums, —*i.e.*, on the affected side,—from which the bulk of the teeth, the molars and premolars, had been fruitlessly removed.

Further questioning elicited the statement—and it was an all-important point in her history—that during the entire period of twelve years she had had but one remission, — *i.e.*, one *complete* remission, —and this had occurred under the following circumstances. Some two years ago her physician had ordered her to Atlantic City. Here she contracted severe rheumatism, which affected mainly the lower extremities. The attack lasted upwards of eight weeks, and during all of this time she was free from her tic douloureux. Just as soon, however, as the rheumatism subsided her tic reappeared, and had continued with varying degrees of intensity up to the present time.

Notwithstanding this history of a prolonged remission, I hesitated about giving the patient any encouragement. She had been under the hands of various physicians, who had made unusual efforts in her behalf, and who had finally pronounced her case incurable. I, too, told her that we could expect but little from drugs, and that the only remedy that suggested itself to me was a surgical procedure, the propriety and results of which were themselves open to question. I referred to nerve-stretching, which I briefly explained to her. She expressed herself as willing and even anxious to have trial made, saying that "if it didn't kill her it couldn't make her any worse." I left her without writing a prescription, promising to call again in a few days.

Two views, of course, presented themselves regarding this case: one that it was

of organic origin, the other that it was symptomatic of some general disease or condition. In favor of the first view was the long-continued existence of the affection. The latter had existed for twelve years, but it appeared to me that the history of a marked and prolonged remission of eight weeks rendered an organic origin extremely improbable. Certainly we should not expect a diseased bone or membrane to accord with such a history. On the other hand, it was difficult to accept the second view. The patient presented no evidence of a constitutional trouble. Her general health, as it so often is in these cases, was good. There was no evidence of specific disease, and no affection of the kidneys. The patient's history suggested a doubtful connection of rheumatism with the trouble, but it seemed strange that, if rheumatic, the latter should have persisted for so many years.

I finally decided, before attempting the operation of nerve-stretching, to test the question of rheumatism very thoroughly; and, accordingly, at my next visit I prescribed oil of gaultheria in fifteen-minim doses, to be taken every three hours. After four days had elapsed I called again, and, to my surprise and pleasure, found that my patient was decidedly better. The paroxysms were far less frequent and much less painful. The hyperæsthesia of the cheek and gums had also altogether disappeared. The physiological action of the salicylate was evidenced by decided tinnitus. I directed the remedy to be continued, and called at intervals of three or four days until December 20, when I found my patient suffering from a diarrhœa, the result of an indiscretion in diet. Up to this time she had steadily improved, and she was to all intents and purposes well. Previously she had never been able to eat without exciting pain. The pleasure of eating with comfort had resulted in eating too much, and hence the diarrhœa.

I now stopped the oil of gaultheria, and for a number of days directed my attention to her digestion. The diarrhœa was promptly relieved, and on December 24 she ventured out of the house. It was early in the morning, there was snow upon the ground, and it was very cold. This exposure was followed by a mild recurrence of the tic. She had a few paroxysms of moderate severity. She of her own accord resumed the oil of gaultheria.

On December 26 I saw her again, and now replaced the oil of gaultheria by salicylate of sodium, of which I gave twenty grains every four hours. This she tolerated well. Every trace of tic douloureux now disappeared. She voluntarily increased the dose of the salicylate to thirty grains, thus taking one hundred and twenty grains a day. Her fear of a return of her terrible affliction caused her to persist in this excessive dose until December 29, when, upon my urgent advice, she diminished the dose to twenty grains three times a day. The large doses had caused marked depression, her tinnitus was excessive, she was decidedly deaf, and I fancied that her pulse was weak. Besides, she was taking very little food, and her digestion was much impaired. Although she had not the slightest return of pain at any time, she persisted in the use of the salicylate until January 12, when it was finally abandoned.

Since that time she has been exposed to bad weather on numerous occasions and at various hours of the day and evening. Upon one occasion, indeed, she caught a severe cold, which gave rise to a severe bronchitis, but without any return of the tic douloureux. At present writing she is entirely well. How long she will continue so is, I confess, a matter of doubt. However, I believe that the present cessation of the pain is directly due to the action of the salicylates, and to nothing else. The effect was too sudden and striking to be attributed to other causes. When the oil of gaultheria was stopped on account of the intercurrent diarrhœa, the pain reappeared, but immediately ceased when the salicylate was resumed. I believe also that the good effects of the drug were due to the large doses employed.

The mode of action of the salicylates in this case is a matter of interesting speculation. It is possible, of course, that the affection was rheumatic in its origin, and that the salicylates were efficient on this account. On the other hand, it is not impossible that the remedy acted in another and entirely different way, and the following hypothesis seems to me plausible. That salicylic acid acts directly on the nervous system cannot, I think, be doubted. To me the single fact of the ringing in the ears is an evidence of such action, and the further fact that increased doses result in deafness a confirmation of this idea.

Now, if salicylic acid produces ringing in the ears and even deafness, it is probably by a direct action of the drug on what we may call the acoustic protoplasm. That is, the acoustic protoplasm is *molecularly impressed;* it has the rates and directions of its molecules so affected as to give rise first to abnormal sensations, and finally it has the molecules so much arrested or inhibited as to give rise to an entire loss of function. May it not be that the action of the salicylate in this case is due to its modifying impress on the abnormal movements going on in the molecules of the diseased nerve? and is it not possible that it deadened the hyperæsthesia and annulled the pain by virtue of the same quality by which it produces deafness? I give this speculation for what it is worth.

My hope in reporting this case is that others will give the salicylates a fair trial, even in cases in which there is no rheumatic history; and, further, that in making this trial they will steadily increase the dose until an effect is produced or the limits of safety are reached.

A CASE OF BRONCHO-PULMONARY MYCOSIS.

BY WILLIAM F. WAUGH, M.D.,

Professor of Practice, etc., in the Medico-Chirurgical College.

PERHAPS no other plan of treatment recently proposed has excited so much attention as Cantani's novel method of treating consumption by bacteriotherapy. The singularity of the therapeutic measure, and its apparently logical deduction from recent developments in bacteriopathology and biology, combine to invest it with peculiar interest. But, whether the inference be logical or not,—whether the introduction of bacterium termo into the pulmonary tract, as an antagonist to the bacillus tuberculosis, be a genuine addition to our therapeutic armamentarium, or perchance may turn out to be rather a bringing of the Saxons into Britain,—there are two questions which should be settled before the experiment is made on a large scale.

First, Is the introduction of bacterium termo a safe and harmless procedure? Second, Is it efficient in this case? Both questions should be settled before the method is applied in the treatment of pulmonary tuberculosis; and both could readily be determined by experiments on animals.

Perhaps the history of the following singular case may assist in answering the first question.

The patient is a man, 25 years of age, spare in habit, with delicate digestive organs. His father, when young, had bronchial hemorrhages, but is still alive and reasonably healthy. One member of the family died of phthisis. During the preceding year the patient had suffered with a vesical affection, but had been quite well for some months before the present illness began. He was connected with the management of a cemetery.

One day the body of a woman was brought to this cemetery, with a certificate which gave pulmonary consumption as the cause of her death. Her natural weight was one hundred and thirty pounds, but shortly before her death she had rapidly increased, until the body weighed two hundred and twenty pounds when she died. The body was placed in a crypt in the receiving vault.

Some time subsequently the workmen reported to Mr. B. that there was something wrong with this vault. The door was opened, when it was found that the floor was covered with a putrid substance, which was traced to the crypt in which this body had been deposited. The body of the consumptive woman had burst, and the fluids had overflowed from the coffin and escaped from the crypt.

The stench was pronounced to be something indescribable. So terrible was it that the employees of the cemetery, men who may be supposed to be fully familiarized with such things, could not be induced to enter the vault to clean it out, until Mr. B. set them the example by going down into it himself. Previous to this, large quantities of carbolic acid and of chloride of lime had been thrown into the vault; but even by this means the stench could not be overcome.

As soon as Mr. B. entered the vault and began to inhale fully its mephitic air, he began to shiver and experience the sensations known as "taking cold" in the most intense form.

After remaining at his home for some days, on September 20, 1886, he presented himself at my office. He could scarcely talk for the constant cough. He had a temperature of 102.5°, and stated that he had had night-sweats. There was some redness of the fauces, which disappeared after a few applications of tannin; but the cough was but little relieved. The expectoration was of thin, colorless fluid, very abundant. His sleep was greatly disturbed by the constant coughing. Altogether it was a typical bronchorrhœa.

In the first number of *Progress*, a little foot-note stated that a valuable indication as to

the nature of lung-affections could be drawn from noticing whether the sputa dried up, as a simple bronchial discharge dries up in a few hours, whereas tubercular sputa liquefy and become pure cultures of tubercle-bacilli. Recollecting this, I inquired of Mr. B. if the sputa became dry, and he at once responded that he had noticed with surprise that they did not, but that, after remaining in a receptacle from morning till evening, the masses were even more fluid than when first expectorated.

It appeared evident that here was an infection of the pulmonary region with some morbific agent. But with what? Was it due to the inhalation of the carbolic acid, of the bacillus tuberculosis (presumably the cause of the woman's death), or of the bacterium termo, the agent of decomposition, which evidently was at work in the fetid vault?

His body exhaled the odor of the acid for days after he entered the vault. But the action of this agent, which might set up a broncho-pneumonia, would not account for the bronchorrhœa.

To settle the question, I procured a specimen of his sputa, and sent it to Dr. De Lannoy, of the Medico-Chirurgical College, with a request that he should examine it microscopically. I subjoin his reply:

"Professor Waugh,—The sputum, which I examined very carefully, contains *no tubercle-bacilli, but fairly swarms with putrefactive forms, the so-called microbacteria; these occur in zoöglœa as well as in chains.*

"The epithelium from the air-vesicles is strongly pigmented. This change is to be attributed to broken-down blood-corpuscles which have parted with their coloring matter.

"If this sputum be perfectly fresh, it certainly does, as such, contain an extraordinary number of microbacteria.

"From what you said of the trouble, I judge it to be lodged in the smaller bronchi. The presence of vesicular epithelium, pathological in character, would corroborate this, and the necessarily long-continued retention of the expectorated matter might account for the large number of micro-organisms.

"Yours very truly, C. W. De Lannoy."

During the succeeding two months the patient improved somewhat under a carefully-directed treatment, but did not recover his accustomed health. Full alimentation was enjoined. The ordinary remedies for bronchorrhœa were tried, including Griffith's mixture, cubebs, copaiba, lactophosphate of lime, turpentine, and benzoin. The use of hydronaphthol with an atomizer proved more beneficial than anything else which I tried.

But after two months of treatment I was compelled to send him to San Antonio, Texas. At the time he departed his fever had not quite disappeared, and the expectoration had diminished greatly, but still retained its fluidity, and if treatment were suspended for a few days it increased to its first proportions.

Since his arrival in Texas he has improved very much, has increased thirty pounds in weight, and has gained in strength and in spirits. The cough and expectoration have decreased, the fever scarcely ever appears, but he has on several occasions expectorated a little blood. From his letters I judge that a certain amount of pneumonic phthisis has supervened. An examination by a skilful physician of San Antonio failed to detect any sign of tubercular disease or of tubercle-bacilli in the sputa. I do not as yet feel justified in allowing Mr. B. to return to this climate, especially at this season. The improvement still continues, and in all probability he will make his permanent home in Texas.

Altogether, this appears to me a case of infection with putrefactive bacteria. It shows that *Progress* went too far in claiming the liquefaction of the sputa as a certain sign of tuberculosis, as it may be due to the presence of other bacteria. It may throw some light on the etiology of other cases of bronchorrhœa, not colliquative in character. Finally, it should make us cautious in instituting extended trials of Cantani's method, until experiments on inferior animals have demonstrated the value of bacteriotherapy as compared with its dangers. At any rate, it seems better policy in the human body, as in the body politic, to strengthen the system against the attacks of the enemy rather than to introduce foreign auxiliaries.

RENAL INADEQUACY AS A CAUSE OF INSOMNIA.

BY LAMBERT OTT, M.D.,

Member of the Philadelphia Neurological Society.

THIS subject—renal inadequacy as a cause of insomnia—was called to my notice incidentally while having a case under treatment. The patient was a man,

aged 30 years, leading a sedentary and literary life. He endeavored by out-door exercise, good habits, and careful meals to avoid the many physical and mental perversions which usually beset the hard-working *littérateur*. He had occasional and apparently causeless attacks of sleeplessness, occurring sometimes in the earlier parts of the night, and oftener after the midnight hour. He has often lain from two to six o'clock in the morning, utterly unable to sleep, but not suffering pain or headache; nothing more than great restlessness, a tossing from one side of the bed to the other, lying awhile on the back, then on the side, and so on, changing every few minutes; and when he determined to remain in one position until sleep came, an indescribable tired sensation and soreness pervaded the body, especially the limbs, and before his will-power could intercept the act his body had involuntarily changed to another position.

I tried all available means to effect a cure, and upon asking for a sample of urine for examination he informed me that in those nights when he suffered most there was very little urine passed. Accepting the hint, the next bad night I had the quantity measured, and found that from seven in the evening till six o'clock the next morning he passed only one-half ounce, the following day passing the usual amount. I examined this half-ounce of urine passed, and found it scant in sediment, not highly colored, slightly acid in reaction, negative as to albumen and sugar, and normally proportioned as to uric acid and urates, and increased as to triple phosphates and oxalate of lime.

In obedience to my directions, he took more out-door exercise, and drank water freely, with an improvement in his sleep and a nocturnal increased flow of urine. He took at the same time digitalis three times daily for an irritable heart, which, by increasing the intravascular pressure, indirectly assisted in causing the greater secretion of urine. He improved under this treatment, the insomnia disappearing. Later he disregarded my precautions, and relapsed, having sleepless nights and a scanty flow of urine. The urine was examined with the same results.

First night of insomnia he passed one-half ounce of urine; second night, one and one-half ounces; third night (treatment instituted), six ounces.

During the relapse he passed the following quantities: First night of insomnia, three-fourths ounce; second night, three ounces; third night (treatment instituted), eight ounces.

He occasionally relapsed, and during these sleepless nights he had always renal suppression. Repeated examinations for albumen and sugar were negative; but an abundance of phosphates and oxalate of lime was found.

The question arises, Is the renal inadequacy a cause or an effect of the nervous disturbance? Reasoning from analogy, we may conclude that it is the cause. In the lighter forms of uræmia there is sleeplessness preceding the convulsions and coma. Is it the retention of the urine-salts or the altered intravascular pressure that is the disturbing element? These are questions to be solved.

The treatment most successful was as follows. Copious drinking of water two hours before going to bed, and just before retiring a full glass of beer. During the waking hours he took digitalis, added to a general hygienic regimen. The patient noticed that when he diminished the quantity of drinking-water at the time there was a tendency to insomnia he rested badly, and it seemed as if the gradations of sleep were regulated by the quantity of water drunk. The case is of interest, and may suggest research leading to a valuable clinical discovery.

1531 North Seventeenth Street.

TRANSLATIONS.

Operative Treatment of Empyema.—M. Guermonprez, of Lille, reported to the Société de Chirurgie the case of a man, 27 years old, who had pain in the right side of his chest, cough without expectoration, and dyspnœa. Later a most fetid expectoration appeared, with increasing emaciation and weakness, and an abscess pointed in the ninth intercostal space. When opened, it was found necessary to resect portions of the ninth and tenth ribs. The pleura was much thickened, and a circumscribed empyema was detected. A superficial slough was removed from the pulmonary surface, and a drainage-tube inserted. A return of the symptoms was relieved by frequent washing out of the abscess-cavity with

corrosive sublimate solution, and recovery followed.

The question of the surgical treatment of empyema has also been discussed by A. Kasauli (*Wratsch*, 1886) in a report of twenty-one cases in the surgical wards of the Odessa Hospital, under Dr. Duchnouski. The cases were principally young soldiers, the empyema usually succeeding upon a croupous pneumonia, but in three there was tuberculous disease of the lung and pyo-pneumothorax. Ten of the cases died,—five with tuberculosis, one with tetanus, one pericarditis, one septicæmia, and two from exhaustion. Of the others, three retained a fistulous connection; eight recovered completely, with a linear scar at the point of operation. Fifteen out of the twenty-one cases required resection of one or more ribs; in one case the resection was performed on both sides. The drainage-tube remained *in situ*, on an average, about thirty-four days; the bandages were removed only every three or four days; the pleural sac was very seldom washed out. The patients recovered, on the average, in about forty-four days. The method of Dr. Duchnouski is as follows. In case of large collection of fluid and displacement of the heart, a preliminary aspiration is made from seven to ten days in advance, so that by the time of operation the organs have resumed an approximately normal position. A bottle about one-fourth filled with sublimate solution is attached to a rubber tube, the end of which dips beneath the surface of the solution. As soon as a portion of the rib is removed, a small opening is made into the pleura and the drain inserted; it is then stitched to the skin, fastened with a spring clamp, and attached to the gum tubing and bottle. After the antiseptic dressings have been applied, the clamp is to be removed, and the pus flows gradually through the tube into the bottle. On account of the pressure in the pleural cavity, the solution does not ascend into the chest. At the end of twenty-four hours the bottle is changed, and the quantity of pus measured. Forty-eight hours after the operation the bottle is to be removed, and the pleural wound enlarged, irrigated, and drained. Antiseptic dressings are then resumed. By this procedure, irritation of the pleura, hemorrhage, violent coughing, and dyspnœa are avoided. This has given very satisfactory results.—*Centralblatt für Chirurgie*, No. 10.

Treatment of Diphtheritic Croup during the Period of Incubation.—Dr. Dumas broaches the question in the *Bulletin Général de Thérapeutique*, January 30, "Is there any antiseptic medication for croup during its incubation period?" After the disease has become developed, treatment of all kinds is often futile. Cases differ very widely, however, in their degree of malignancy. In the same family in which fatal cases occur, others may appear in which the disease is confined to a patch of false membrane on the tonsils without other symptoms. The problem sometimes arises as to the treatment of children or others known to have been exposed to contagion. In such a case it is an assumption warranted by experience that they will have an attack of diphtheria. When such an exposure has occurred, the usual course followed is isolation of the cases, frequent examinations of the throat, and attempts to destroy the false membranes immediately upon their appearing by applications of perchloride of iron, papayine, lemon-juice, etc. These, with pepsin solution, are to be preferred to nitrate-of-silver applications, formerly so highly praised. Dumas has used for several years the tincture of iodine as a preventive of diphtheria, given after exposure, in the following combination:

℞ Aquæ, 80 G.;
Aquæ aurantii florum, 20 G.;
Tincturæ iodi, viii gtt.;
Potassii iodidi, 10 cgr.;
Syrupi, 20 G. M.

To be taken in twenty-four to thirty hours, in half-teaspoonful doses. To be continued for about a week.

In several cases in which this antiseptic treatment has been used the results have been satisfactory. It is quite innocuous, and no bad symptoms have been observed.

This method is certainly worthy of a trial in hospitals for children, and in infant asylums, where croup often prevails.

Hydrocele treated by Injections of Corrosive Sublimate.—An aqueous solution of one to one-thousand of the bichloride of mercury, used in the same way that tincture of iodine has been employed in the treatment of hydrocele, is advocated by Sarrazin (*Thèse de Paris*, 1885, No. 190). It is aseptic, although it acts as an irritant and causes slight pain; inflammatory reaction ensues, and adhesion takes place.

PHILADELPHIA
MEDICAL TIMES.

PHILADELPHIA, APRIL 16, 1887.

EDITORIAL.

THE NEUROTIC COMPLICATIONS OF DIABETES.

THE nervous disturbances complicating diabetes have attracted the attention of a number of careful observers. Disturbances of sensation, such as diminution of the tactile sense, formication, itching, and pricking, are more or less frequent symptoms. Pruritus vulvæ has long been recognized as a symptom of the disease. Pains in the joints simulating rheumatism are also sometimes observed. A practical point of some importance is that these pains rapidly yield to salicylic acid. This drug has lately been used to a considerable extent and with some success in the treatment of diabetes itself.

Among the most frequent and characteristic sensory disorders of diabetes is an uncomfortable feeling of weight and fatigue in the thighs. This is not much increased by exercise and not mitigated by rest. In fact, it is generally more decided in the morning, on arising from bed. During the day it seems to diminish, sometimes passing off entirely.

Another frequent symptom is headache. This is sometimes merely a sensation of pressure or heaviness; at other times neuralgic pains in the frontal, occipital, and post-cervical regions; and occasionally a typical "sick headache."

Sciatic neuralgias, generally bilateral and extending to the sural and plantar branches, are occasionally present in diabetes. The pains are very severe, and often suggest some structural disease of the spinal cord. According to Ziemssen, these neuralgias are partly, at least, due to a neuritis. The nerve-pain may also be localized in the dental and intercostal nerves, or in one of the internal organs,—stomach, ovaries, kidneys, or uterus.

Motor pareses or paralyses, in combination with sensory disturbances, are also observed sometimes. A case is recorded by Lecorché in which tetanoid spasms accompanied by pains occurred in the forearms and legs. Cases not infrequently simulate locomotor ataxia, many of the characteristic symptoms of the latter disease being present, including the abolition of the patellar tendon reflex. In fact, absence of the tendon reflex seems to be a frequent symptom of diabetes, for in the statistics of Bouchard, who first called attention to the relation of the knee-jerk to diabetes, this phenomenon was absent in thirty-seven per cent. of the cases. This observer's figures show further that the abolition of the patellar tendon reflex is a symptom of grave omen in diabetes.

Several cases have been reported in which sugar appeared in the urine during the course of multiple sclerosis. The explanation offered for this is that a sclerotic plaque in the floor of the fourth ventricle gave rise to the glycosuria. In these cases the knee-jerk was increased, and no other symptom of diabetes beyond the saccharine urine was present.

In the neuralgic and paretic complications of diabetes, massage and the constant galvanic current are serviceable, in addition to the usual well-known remedies addressed to the morbid condition of the system. Among the latter, opium, codeine, salicylic acid, and ergot seem to promise most success.

HYPNOTISM IN A NEW RÔLE.

SINCE the observations of Braid in 1842 upon provoked somnambulism, many volumes and essays have been written upon this neurosis. Of late years a number of new facts have been brought

to light, especially by the studies of Charcot and Richer at the Salpêtrière, and of Dumontpallier, Bernheim, Beard, and others. In minor surgery, hypnotism, as this state of artificially-induced somnambulism has been called, has proved a valuable expedient. Esdaile and others have reported a large number of surgical operations performed while the patient was in this state, without consciousness or suffering, although no anæsthetic was given. The same expedient has been recently resorted to in Germany in childbirth, with reported satisfactory results; and experiments are now making with this expedient in treating mental disorders, with fair promises of success.

At the meeting of the Académie de Médecine* (March 15) M. Mesnet reported the details of a remarkable case of a young man, 19 years of age, who had been a somnambulist since his thirteenth year, and had once been arrested for pilfering from a merchant's stand while in this peculiar mental state. Being taken to the Hôtel-Dieu, he exhibited most decided evidences of somnambulism: anæsthesia and analgesia were complete, and there was also loss of temperature-sense except in certain symmetrical regions. Hypnotism was readily induced by the usual method, and the ordinary phenomena were exhibited. Upon restoration of consciousness there was no recollection of what had passed; but, upon inducing hypnotism again, the memory was restored of what had occurred in the preceding condition.

Among other orders given to him were to return upon the day after to-morrow and to purloin the watch from the pocket of a certain by-stander. At the appointed time he passed into the hypnotic state, and at once performed the act without any prompting. Subsequently the patient had a severe attack of hystero-epilepsy, and upon recovering his senses seemed entirely unaware of what had occurred.

The possibility of human automatism being admitted, the medico-legal relations of such cases deserve study. A similar case, that of a young married woman who asked for divorce upon the ground of undue influence, some months ago was the sensation of the hour in Paris courts, and has already attracted the attention of the novelists.

Our courts of law, already puzzled with the question of moral and legal responsibility in neurotic subjects, will find hypnotic automatism quite as difficult a problem to decide.

* La France Médicale, No. 33, 1887.

STATE BOARD OF HEALTH.

THE sixth regular meeting of the State Board of Health was held in Harrisburg on Thursday, April 14. While much routine business of importance to the State was transacted, the chief interest of the occasion to the public centred in the annual address before the Board, which was delivered in the hall of the House of Representatives on the evening of the same day, by the Hon. E. A. Wood, M.D., of Pittsburg, formerly a member of the State Legislature, and well remembered by his colleagues in that body as a brilliant, forcible, and witty speaker. His address was worthy of the occasion, and constituted an intellectual treat to all who had the good fortune to be present.

THE PHILADELPHIA COUNTY MEDICAL SOCIETY held a stated meeting on the 13th instant, and again put itself upon record in opposition to the American Medical Association upon the question of the right of women to membership. The Council, among other candidates, nominated Dr. Anna E. Broomall, who failed, however, to get the requisite two-thirds vote.

LEADING ARTICLE.

OBSERVATIONS ON THE OCCURRENCE OF FREE HYDROCHLORIC ACID IN THE STOMACH; ITS RELATION TO DIGESTION, AND THE DIAGNOSTIC IMPORT OF ITS INCREASE OR DECREASE IN DISEASE.

INCREASED attention has been directed during the past few months, on the continent of Europe, to this subject, which has been almost totally neglected in America.

Among the numerous investigations reported, we notice the careful studies of Riegel as particularly worthy of attention (*Zeitsch. f. Klin. Med.*, B. xi. H. 2 and 3). In one year he made thirteen hundred and seventy-nine chemical examinations of one hundred and twenty-two cases, and concludes that there are four conditions of the secretion in diseases of the stomach: 1st. It is normal. 2d. Free HCl and the peptic strength is diminished or absent. 3d. The amount of the organic acids is increased, although HCl is also present. 4th. There is an excessive secretion of HCl.

He departs from the method of Leube,—who uses some irritant, as ice-water, to excite the secretion of the gastric juice,—and pursues the following plan. He gives the patient a meal consisting of a mixed diet, and, after six or seven hours, removes the *undiluted* gastric contents with the sound. Digestion should be complete after seven hours; therefore, if any portions of undigested food remain, it is a proof that the process has been abnormally delayed. The matter obtained is tested for its reaction and peptic strength, and for the presence and amount of free HCl and of the organic acids. He states that vomited material cannot be utilized for purposes of examination, a fact corroborated by our own experience. Free HCl does not normally occur in the stomach until about three hours after the ingestion of food, and vomiting usually takes place before this time has elapsed.

He claims that HCl is almost constantly absent in *carcinoma ventriculi*, and that the peptic strength is lacking. This absence of acid is the surest symptom of the disease, and where acid is present he thinks the diagnosis of carcinoma is not warrantable. During an experience of seven years he has never known this sign to fail. In certain cases also of a reflux of bile into the stomach he found HCl and pepsin absent.

On the other hand, in *ulcus ventriculi* the quantity of free HCl is usually increased. In *simple dilatation* the acid is almost always present, and is sometimes increased in amount, and the organic acids are often abundant; while in *chronic dyspepsia* there is oftener an increase than a diminution of the quantity of HCl,—contrary to the view very generally held. Lactic acid persists in this disease for a longer time after meals than is normally the case.

In some clinical observations in the *Deutsche Med. Wochensch.*, Nos. 47, 48, and 49, 1886, Korczynski and Jaworski detail the examination of fifty-two cases of ulcer or of cancer of the stomach. The function of the viscus was tested in three ways. 1st. Aspiration after strict fasting was practised. If nothing was obtained, one hundred cubic centimetres of distilled water were ingested and the operation repeated, and the gastric contents chemically tested. 2d. A modified Leube's ice-water method was employed. 3d. The digestive power of the stomach was tested by the ingestion of portions of boiled white of egg, the contents of the stomach being then aspirated after a certain length of time. Their results confirm the statement made by Riegel and others, that free HCl is absolutely essential to digestion, pepsin alone not being sufficient. This is certainly a matter to be remembered in our treatment of gastric disorders.

In twenty-four cases of *ulcer* they found the gastric secretion always increased in quantity, present even after fasting, and always containing a considerable amount of HCl.

In twenty-eight cases of *cancer* digestion was always retarded, and in many instances the stomach was found to contain remnants of food, even after fasting. HCl was present in but two patients, both under thirty years of age.

The authors conclude that free HCl is almost invariably absent in cancer, but do not agree with Riegel that this is due to the action of the cancerous juices upon the gastric secretion, rather believing that an already established mucous catarrh, with an absence of HCl, as seen in old

persons, predisposes to the development of the neoplasm.

The modified Leube's ice-water method referred to is described by Jaworski and Gluzinski in the *Zeitsch. f. Klin. Med.*, B. xi. H. 2 and 3. It consists in the administration by the sound of two hundred cubic centimetres of ice-cold water upon an empty stomach. The sound is then withdrawn, and after ten minutes reintroduced and the contents of the stomach aspirated, without the addition of more water.

Sansoni (*Rivista Clinica*, No. 10, 1886) has made a careful study of four cases of cancer, and found HCl in no instance. In numerous other cases, not cancerous, HCl was always present in men, but often absent in women, especially in hysterical subjects. He thinks this is due to a longer continuance of the food in the stomach of women, and the subsequent absorption of the acids by the peptones. He considers the absence of free HCl an important corroborative sign of carcinoma.

Many writers have disputed the statement that free HCl is absent in cancer of the stomach. Among the more recent of these are Cahn and V. Mering (*Deutsch. Arch f. Klin. Med.*, B. xxxix. H. 3 and 4),* who claim that the methyl-violet test usually employed is entirely unreliable, since other substances besides HCl may give the same reaction, and still others may hinder or conceal it, though the acid be present. They have, therefore, made accurate chemical analyses of the secretion, and reach the conclusion that both lactic and hydrochloric acids are present with a mixed diet, while with animal diet the latter alone is to be detected. They believe, too, that HCl is usually present in cases of carcinoma, although perhaps in smaller quantities than usual. On the other hand, it may be occasionally absent in fever and in severe anæmia. In this connection we may note that Ewald claims that lactic acid develops even after a purely animal diet.

Yet the greater weight of evidence goes to show that the absence of HCl, at least as indicated by the ordinary tests, is a very important diagnostic sign of carcinoma. The subject is certainly worthy of the attention of American physicians.

Regarding the tests which have been employed, Riegel advocates tropæolin, methyl-violet, and Congo paper for HCl, and Uffelmann's carbolated-iron test for lactic acid. Numerous others have been recommended. Our own experience has led us to put most faith in the methods with methyl-violet and carbolated iron. We have made no trial of Congo paper, and tropæolin and fuchsin have proved unsatisfactory. The tests are easily performed as follows:

1. To a weak aqueous solution of methyl-violet in a test-tube, add a portion of the filtered gastric contents. The violet color becomes distinctly blue if HCl be present. The test is delicate for one and one-fourth parts HCl in one thousand of the filtrate.

2. Make a mixture of an aqueous solution of the sesquichloride of iron and a very concentrated solution of carbolic acid. The quantities are best determined by experiment. An amethystine-colored fluid is produced, which becomes a bright yellow when added to the filtrate, if lactic acid be present. This test-fluid must always be freshly prepared. The reaction is delicate for one-half in one thousand.

We should not fail, too, to test the peptic strength by allowing the filtrate in a test-tube to act for a certain time upon a portion of boiled egg-albumen. This should be done at a slightly-elevated temperature, to obtain which the heat near the kitchen-range will answer if no thermostat be available.

J. P. Crozer Griffith, M.D.

NOTES FROM SPECIAL CORRESPONDENTS.

LONDON.

THE hope that some of the Erasmus Wilson bequest may be used for founding surgical research laboratories has been cherished by many of the younger generation; but few perhaps were prepared to see so unanimous an expression of opinion from old and young as is contained in a memorial addressed to the Council of the Royal College of Surgeons and signed by all the teachers of surgery in London not on the Council, with, it is said, two exceptions. The memorial points out that laboratories are sorely needed for the study not only of morbid anatomy, but also of experimental pathology, including bacteriology and experimental operative surgery. The anti-vivisectionists, perceiving an opportunity, are taking steps to

work upon the fears of the Council and to raise a popular agitation against the proposal. For the last few years, however, their efforts to put increased obstructions in the way of scientific progress have not been very successful; most reasonable laymen are satisfied that the practice of vivisection is under sufficiently severe restrictions already. It is otherwise, however, with a certain noisy knot of lay-women.

The British Medical Association meets this year in Dublin. The President of the meeting will be Dr. John T. Banks, Regius Professor of Physics in the University of Dublin. An address in medicine will be delivered by Professor Gairdner, of Glasgow; in surgery by Professor Edward Hamilton, of Dublin; and in public medicine by the senior Fellow of Trinity College, Dublin, the Rev. Samuel Haughton, physicist, physician, anatomist, mathematician, divine, and politician,—the very embodiment of the ideal cultivated Irishman and of Coleman's *five* single gentlemen rolled into one,—mentally, that is to say. The meeting begins on August 2, and ends on August 5, thus leaving a clear month before the date fixed by the International Medical Congress at Washington. It will be possible to visit Killarney, Donegal, and other places of interest in Ireland, and then to catch steamers to America at Queenstown or Lough Foyle. The Local Honorary Secretary of the Dublin meeting is Dr. George F. Duffey, of 30 Fitzwilliam Place, Dublin.

There seems to be no doubt that laparotomy is being performed in England much more frequently than was the case even a year ago. It has been resorted to in a considerable number of cases of acute peritonitis, and mention is made of cases of abdominal injury in which it has been used. For instance, Mr. Croft recently operated on a man in St. Thomas's Hospital who was admitted for abdominal injury, with blood in the peritoneum. The hemorrhage was found to proceed from a ruptured spleen; the organ was excised, but the man succumbed. It seems, however, safe to prophesy that this operation will some day be successful. Many animals have survived excision of the spleen, and a black-and-tan terrier upon which Professor Gamgee had performed the operation a good many years ago used to be a familiar visitor at the Jodrell Laboratory at University College, looking the picture of sleek health.

In another case of abdominal injury with symptoms of acute peritonitis in a man, Mr. Croft opened the peritoneal cavity and found that the small intestine had been ruptured. The peritoneum was thoroughly washed out, the two ends of the severed intestine secured in the abdominal wound, and the man has since been doing well. It is also stated that Mr. Walsham has treated a case of rupture of the bladder by laparotomy, sewing up the wound in the bladder and washing out the peritoneum. The man, it is reported, was convalescent in a few days.

Dr. Mitchell Banks read a paper recently at the Harveian Society of London in which he recommended that in operating for mammary cancer the surgeon should excise the whole mamma, with the overlying skin and subjacent parts, and should open up the axilla and tear out all lymphatic glands, whether enlarged glands could be felt before operation or not. Statistics given by Mr. Banks showed a higher mortality, but Mr. Harrison Cripps thought that this need not be the case if there were no "septic surroundings." Mr. Butlin severely criticised Dr. Banks's proposition, and quoted statistics which really seemed to prove too much,—namely, that recurrence occurred earlier after the more extensive operations. He, however, himself suggested the explanation, which doubtless is that the cases where enlarged glands cannot be felt in the axilla, and in which therefore most operators would not open the axilla, are those which are least malignant or in the earlier stage.

Professor Virchow, during a short visit to this country, was shown a number of cases of spontaneous myxœdema in man by Dr. W. N. Ord, and the "operative myxœdema" which has been noticed in monkeys after excision of the thyroid gland by Mr. Victor Horsley. From a paper which he has since published, it would seem that the great pathologist has been led by what he saw in this country to modify materially the views he expressed at the Copenhagen Congress. He is a convert to the doctrine that myxœdema and the "cachexia strumipriva" of Kocher are one and the same disease, in some way inextricably connected, in the one case with atrophy or destruction and in the other with ablation of the thyroid gland. The Clinical Society here appointed a committee two years ago to inquire into the nature of myxœdema, and so far as regards the general etiology, symptoms, and morbid anatomy, the report is almost ready. A circular has been sent to every surgeon in Europe known to have performed thyroidectomy, asking whether symptoms of myxœdema (cachexia strumipriva, *myxœdème opératoire*) have been observed to follow the operation. None of these circulars have been sent to America, because it is not known to the committee that the operation has ever been performed there; but if any of your readers have had cases, I am asked to say that Dr. Felix Semon (39 Wimpole Street, London) would be glad to have particulars of the results, and, not least, if in any of the cases thyroidectomy had been performed without resulting myxœdema.

The Clinical Society at its last meeting appointed yet another committee, consisting of Messrs. Christopher Heath, Howard Marsh, Haward, Rivington, and R. W. Parker, to re-

port on the treatment of scoliosis. The question was raised by a paper read by Mr. Keetley, in which he contended that a test case treated by Mr. Bernard Roth, who advocates a course of gymnastics as the best line of treatment, had not been improved by the method, but that, on the contrary, the curves had increased and the patient had lost in height, though she had improved in spirits and muscular strength. Mr. Roth responded with some warmth, protesting that unless his reply was also published it would be unfair to publish Mr. Keetley's paper in the Transactions. Whereupon the committee above mentioned was appointed.

Several cases have recently been reported in which chronic obstruction of the bowels has been produced by gallstones. There can be little doubt that calculi sufficiently large to produce this result must find their way into the duodenum or some other part of the intestine through a direct fistulous communication between the gall-bladder and the gut. Dr. Pye-Smith mentioned two cases at the Pathological Society's last meeting in which there had been no history of any attacks of abdominal pain or biliary colic, the first symptoms being those of gradual intestinal obstruction. In other cases the symptoms, however, are more acute, and I have heard of one, not yet published, in which laparotomy was performed, and the calculus, which was tightly grasped by an inflamed section of small intestine, was removed through an incision in the gut. The patient, unfortunately, did not recover.

During a short discussion on the treatment of syphilis at the Medical Society recently, Dr. Lauder Brunton discussed the germicide theory of the action of antisyphilitic remedies. Mercurial salts are germicides, and iodine is a germicide; but iodide of potassium, the drug which is so universally given in the later stages of syphilis, is not germicidal. His conclusion was that while it was probable—or perhaps it would be more correct to say not improbable—that mercury acted on the disease-germ, iodide of potassium acted on the diseased tissues. The iodide is a very diffusible salt, and probably its chief action is to stimulate the nutrition of the tissues, and especially of the cell-elements. It is a favorite doctrine with those who look at therapeutics solely from the chemical side that mercury and iodide of potassium ought not to be given together, because the latter hastens the elimination of the former. The theory, however, appears to assume that it is advantageous to store up mercury, to let it accumulate in the tissues; whereas the true aim is to stimulate tissue-growth by the iodide, while at the same time the injurious influence of the syphilitic poison is held in abeyance by the mercury, the hope being that the new tissue-elements produced under these conditions will be healthier than those they replace. Mr. Milner, who started the discussion mentioned above, recommended the green iodide of mercury, Donovan's solution, and iodide of sodium in the treatment of syphilis in hard livers who drink to excess, while using inunction in more abstemious persons, and in dark-complexioned people with a tendency to the tubercular form of syphilide.

Professor Victor Horsley has given a lecture at the Royal Institution, on "The Brain-Surgery of the Stone Age." It is a novel subject in this country, though the Broca Museum of Anthropology in Paris contains ten almost perfect crania and fragments of sixty others illustrating the fact that the men of the polished stone age used to trephine with considerable frequency. Clearly many of the patients survived the operation, for the majority of the crania showed pathological changes only to be accounted for on that supposition. As nearly all the trephine-holes were in the motor areas, it seems probable that prehistoric man only trephined for traumatic epilepsy: that is to say, when a fracture of the skull led to convulsions, he trephined at the seat of fracture and removed a circle from the fractured bone. The fragment thus removed appears to have been regarded with superstitious reverence, and was worn as an amulet.

By a singular piece of good fortune, Mr. Henry Morris has been able to record the sequel of a case which he published in 1879 as an example of recovery from rupture of the bladder. The man died last August, from peritonitis due to a fresh rupture of the bladder. The fundus of the bladder was attached to the rectum by a band hollow at its vesical end; the second rupture had occurred at this hollow part. A committee consisting of Messrs. Savory and Bryant, Drs. Goodhart and Kingston Fowler, reported that the bladder presented all the features which might be expected at a remote period after rupture. The treatment under which the recovery took place consisted of hot fomentations to the belly, half a grain of opium by the mouth every six hours, and the retention of a gum-elastic catheter just within the neck of the bladder. Mr. Morris thinks that the case is strong evidence in favor of treating rupture of the bladder by continuous catheterization.

Mr. W. H. Power, one of the medical inspectors for the Local Government Board, seems to have proved conclusively, so far as statistics can prove anything, that, in some way not easy to understand, a smallpox hospital in a town causes a greater incidence of smallpox in its immediate neighborhood. He has taken the statistics for a great many hospitals, and has written a number of reports to his Board on the subject. One of the most recent relates to the smallpox hospital at West Ham. He found that within an area contained by a circle described three-quarters of a mile from the hospital the death-rate

from smallpox was much higher than in other parts of the same districts; it was never less than twice, and had risen to ten times, the general rate. Mr. Power has also given statistics which tend to show that the number of cases shows a progressive decrease on passing from the immediate neighborhood of the hospital in every direction. No explanation has yet been afforded of the influence of the hospitals. It seems to be independent of the winds, and the explanation at first suggested —that it was due to clandestine or accidental communication between the hospital inmates and attendants and the neighbors—is now found to be inadequate.

England, but especially London, has been recently visited by an epidemic of severe diarrhœa, characterized by severe cramps, chiefly in the lower extremities, watery stools, and great prostration. The cases have been scattered, and no common factor has yet been discovered to account for the wide prevalence of the malady at this time of the year. Cholera has appeared in Sicily recently; but had it been a little nearer, and had the year been a little more advanced when this epidemic of diarrhœa arose, there would undoubtedly have been a scare.

There would seem to be no end to the misfortunes of Guy's Hospital. During the last five years half the physicians and assistant-physicians have died. First Hilton Fagge, then Mahomed, and then Walter Moxon; and now, last week, Dr. R. E. Carrington has succumbed to pleuro-pneumonia after only three days' illness. It is not yet many months since he completed his task of assisting Dr. Pye-Smith to bring out the "System of Medicine" which Dr. Hilton Fagge left unfinished. Dr. Carrington was a man of modest and retiring manners, and was greatly admired and beloved by the students of Guy's Hospital. Dr. Moxon used to contribute short essays to the *Guy's Gazette* ten or twelve years ago. These essays, which are always ingenious and often brilliant, were signed by the curious *nom de guerre* Pilocereus Senilis. A small volume has just been issued by Mrs. Moxon, bearing this name as title. It contains the essays from the *Guy's Gazette* and three addresses. One of the shorter pieces, "Dare quam accipere," discusses in a most humorous vein whether this motto of Guy's Hospital was not meant to apply to the stock mixtures dispensed to out-patients.

Two new special hospitals have just been started in London, where we already have too many. Some time ago, in consequence of what was thought to be the high-handed conduct of the managing committee backed by Dr. Morell Mackenzie, who is the consulting physician, the whole of the staff, with one exception, of the Throat Hospital in Golden Square resigned. A new staff was quickly got together, and the hospital has gone on as before. The old staff, however, with two new recruits, Dr. Coleman Jewell and Dr. Edward Law, who have held the post of resident medical officer at the hospital in Golden Square, have started a new hospital in Great Portland Street; Dr. McNeill Whistler and Dr. Woakes are the senior members of the staff. We have thus three special throat-hospitals in London, besides eight or nine special departments attached to general hospitals. Moreover, two journals of laryngology and rhinology are edited in this country: the one the German *Centralblatt*, by Dr. Felix Semon, the other an English journal, on much the same basis, by Drs. Morell Mackenzie and Norris Wolfenden. Why laryngology is so popular is not quite clear; perhaps the reason is that given once to me by a somewhat fastidious physician, who added it to several other accomplishments he possessed: "It is a nice clean specialty, and does not require any very elaborate instruments." My fastidious friend would have revolted if invited to take up dermatology; but this specialty is almost equally popular, and perhaps more lucrative. The second special hospital is a skin-hospital, and it has been promoted by Mr. J. Startin, who not long ago had some difference of opinion with his colleagues at St. John's Hospital for Diseases of the Skin in Leicester Square. Mr. Startin, who has been joined by Mr. Pocock, intends to place his services at the disposal of the "sick and suffering poor" at a house close to Leicester Square.

DAWSON WILLIAMS.

BOSTON.

THE Massachusetts Legislature of the present year, following the example set by one of its immediate predecessors in regard to the pharmaceutical profession, has passed a bill providing for registration of dental practitioners. All persons now actually engaged in such practice are allowed to register without any examination into their qualifications; but all henceforward desiring to commence the practice of dentistry, whether graduates of a dental college or not, are required to pass an examination before a board of five persons appointed for that purpose by the Governor; and such persons, if approved, and no others except graduates in medicine, are allowed to practise as dentists within the State. In the debate on this bill, one of the speakers produced a letter of protest against the measure from a farmer who had, without any preliminary study whatever, taken up dentistry, who said he had made more in three months than he ever did before, and who defied the legislators to stop him. The opinion expressed by another speaker that "the best dentists were bad enough" seemed to meet with general acquiescence, for the bill passed without serious opposition, though the

parent profession, general medicine, has never received like supervision in the State, every attempt to require an examination and registration of medical practitioners having been defeated under the cry of "Monopoly!" Meantime, Dr. York, of the somewhat notorious "Druidic" University of Maine, having been driven out of that State for fraudulent conduct of a medical school there, is said to be about to make his home in Massachusetts, where every one is at perfect liberty to call himself "Doctor," and to practise upon the community, who chooses to do so.

On the morning of March 14, a local passenger train on a branch of the Boston and Providence Railroad fell through a bridge at a point in the suburbs but within the limits of the city of Boston. Five cars were precipitated into the street below the railroad, a distance of thirty feet or more, and great loss of life resulted. Some twenty-six were killed outright, and eighty or one hundred others injured, many very seriously. The Railroad Commissioners of the State are now conducting an investigation into the cause of the disaster, and, though the hearings are not quite completed, it is pretty evident that the accident was due to causes which might have been prevented. The medical features of the catastrophe have been quite interesting. The earlier scenes at the wreck recalled some of the medical service in the late war. Improvised ambulances were on hand with mattresses, bandages, etc., contributed by persons living in the vicinity. Some of the bodies of the dead were greatly mangled, two having the heads severed from the body, and a third having the skull cleft down its middle and one side of the face torn off. Still others were disembowelled and had the legs torn off. One peculiarity about the bodies of the dead and those whose wounds required surgical attention was the blackness of the skin, suggesting almost the action of fire. Fortunately, however, there was no fire, and the color was shown to have been due to the comminution, the actual pulverization, of portions of the car from the violence of the crush. In one person having a scalp-wound, for instance, the attempt to cleanse the hair from this fine dirt before dressing the wound blackened several successive basins of water as if with soot. Yet that the dirt was not altogether soot from the car was shown by the detection in the washings of many little particles of splintered wood. The railroad company have assumed the medical expenses of all the injured, and will doubtless have to pay a much larger sum in damages for the dead and the living.

Dr. John S. Billings, of Washington, has been appointed for the current year Lecturer on the History of Medicine in Harvard University. It is understood that his course is to be given this spring.

Considerable attention has been attracted by statements regarding a recent outbreak of smallpox among the employees of a paper-mill at Holyoke, Massachusetts. The investigation made by Dr. Abbott, of the State Board of Health,—in company with whom the writer had the pleasure of inspecting the cases,—showed that one man who had worked at a duster in which both foreign and domestic rags were treated, and who had never been vaccinated, died of the disease. Two girls who worked in a room in which foreign rags only were sorted were taken simultaneously at about the same time as the man mentioned. These girls boarded and slept together. Neither had typical vaccinal scars. They were obliged, in going to and from their work, to pass through a room where domestic rags were sorted. In the room where they worked thirty or thirty-five women were employed, but no others contracted the disease. Statements were freely published—one of which I noticed in a valuable medical journal of your city—that the health officer had "traced the disease to foreign rags" brought into New York and bearing a certificate of sulphur-disinfection abroad. This is precisely what was not reported by Dr. Abbott, who found it impossible to conclude with any degree of certainty what sort of rags had carried the infection. As a matter of fact, it is generally impossible to differentiate between foreign and domestic rags as carriers of this infection, for nearly all mills make use of both kinds of rags. Indeed, it seems to the writer that, from what we know of the tenacity of life of the variolous poison, there is little reason for trying to make a distinction in this regard between foreign and domestic rags. If the one can bring smallpox, so can probably the other. Of course, in diseases like cholera, where the contagium is shorter lived and has rarely been carried by rags at all, it is fair to require proof, which never as yet, as I believe, has been offered, that foreign baled rags can transmit the disease before admitting that there is a danger of cholera-infection by this commodity.

An interesting dinner was given the other day in honor of Mr. Theodore Metcalf, one of the leading pharmacists of this city, in celebration of the fiftieth anniversary of his starting in the drug business here. Speeches were made by a number of more or less distinguished men, among them William Warren, the veteran comedian, and Dr. Oliver Wendell Holmes. The latter began his professional career in the same building where Mr. Metcalf kept his shop; and, as the speaker said, he used to write the prescriptions, Mr. Metcalf filled them, and the sexton, who lived opposite, was ready to contribute his part towards finishing up the affair. Many pleasant reminiscences were given of the pharmacists of half a century ago, of whom only one or two others still survive.

C. F. W.

Boston, April 5, 1887.

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA NEUROLOGICAL SOCIETY.

A REGULAR meeting of the Society was held at the Hall of the College of Physicians, February 28, 1887, Vice-President Dr. CHARLES K. MILLS in the chair.

I. N. KERLIN, M.D., read the following paper on

MORAL IMBECILITY.

When reporting to your Secretary the title of a paper to be read before you to-night, I had contemplated prefacing four illustrative cases of moral imbecility with a short discussion on the mooted question of moral insanity, but later consideration led me to reserve this for another occasion, as the illustrative cases are somewhat lengthily detailed and will consume all the time appropriated.

For this evening I present for your consideration short histories of four children,—the first, presented by my friend Dr. Carson, of Syracuse, New York, illustrative of the incipient prostitute whose mental incapacity should be her protection; the second case, the incipient burglar; third, an hereditary religious hypocrite and egotist, who if not permanently sequestered will fill a dramatic if not awful rôle in crime; fourth, a confirmed juvenile tramp and incipient confidence man. All four, in the judgment of your reporter, are cases which may be classed under the following descriptive paragraph, which appears in the Thirty-Second Annual Report of our Training-School for Feeble-Minded Children, and which was quoted by Dr. Hack Tuke in a meeting of the Medico-Chirurgical Association of Great Britain and Ireland, receiving from that learned body an equal share of favorable and unfavorable criticism. The paragraph referred to is as follows:

"It is a mournful conclusion, that has been reached after twenty-five years of experience, that in every institution of this kind, and probably to a far greater extent in our refuges and charity-schools, there exists a class of children to whom the offices of a school-room should not be applied: these are the so-called moral idiots, or juvenile insane, who are often precocious in their ability to receive instruction, but whose moral infirmity is radical and incurable. The early detection of these cases is not difficult; they should be subjects for life-long detention; their existence can be made happy and useful, and they will train into comparative docility and harmlessness, if kept under a uniform, temperate, and positive restriction. The school-room fosters the ill we would cure: in teaching them to write we give them an illimitable power of mischief; in educating them at all, except to physical work, we are adding to their armament of deception and misdemeanor."

And now, as illustrative of this particular group, I cite first the case presented by Dr. Carson [an incorrigible girl sexually insane.]*

Tom McK., aged 12, admitted November 9, 1877. When first brought to our knowledge he was described as an incorrigible boy, who had been passed from one county-home to another, through a juvenile reformatory, and at last, to prevent his own self-destruction, because of his propensity to climb the rods and water-spouts of the refuge and to ramble dangerously over its roofings, he was locked in a secure room. Excepting his under stature, nervous manner, and glittering eyes, there was nothing in the aspect of the pale-faced boy to suggest any unlikeness to normal boyhood. Indeed, his aptness in language, both usual and profane, suggested precocity. He was but little more backward in his studies than would be any neglected boy; full of mischief and deceit, he had the usual indifference of a bad boy to punishment morbidly increased. There seemed to be a moral hebetude and a causeless wilfulness that had taken the place of the fretfulness, kickings, and bitings of his earlier childhood.

The boy promptly responded to school instruction; is described in the early weeks as a "nice little boy, who I think will learn." After two years I find the following record. "Is fourteen years old; reads very well in the second part of the 'Child's Book of Nature;' spells long sentences in the *Independent;* can learn a fair lesson in geography; knows all the counties of Pennsylvania; is in fractions, understanding some of them quite well; writes in No. 3 copy-book; has excellent use of his hands; can make a mattress alone, and cane-seated a chair without help; plays the alto horn in the band; writes a good letter; is kind if his sympathies are aroused, but is cruel if left unguided."

Favorable reports continue to be made of his intellectual progress during the next two years. In 1882 he is spoken of by an indulgent teacher as "a healthy, strong, and fine-looking boy, manly and frank;" but notwithstanding these favorable reports, of which many appear on the pages of our school progress, through the seven years of his pupilage there were seizures of irritability and excitement occurring periodically, and of increasing intensity the longer he remained with us.

The inventions of his cruel nature, directed against child and brute alike, cannot be detailed. The vindictiveness with which he followed up any one against whom might be developed a temporary suspicion was satanic. The secrecy with which he could lay plots to steal from his companions, and the adroitness

* This case was published in full in the proceedings of the Syracuse meeting.

with which he covered up his tracks, were those of an expert.

This side of his character may be known to but few of our resident family, the majority being impressed with this bright-faced boy very much as was the indulgent teacher above quoted.

The period of his discharge from the institution had arrived, and Tom was restless to return to his people, and they equally determined to have him do so. Six months after his discharge I was importuned to testify in court for his release from imprisonment. In the brief period following his dismissal from the institution he had already been found guilty of two or more petty burglaries. Benevolent friends had discovered him in prison, freely confessing his offences, and weepingly imploring to be sent back again to the institution. The crimes seemed to be unaccompanied with sufficient motive to make them heinous.

After a thorough and painful review of his whole life with us and the discomforts that must follow his readmission, I was compelled to advise that the course of the law be not interfered with, but urging that an intermediary, such as that at Elmira, should enter the scheme of our penal treatment.

This incorrigible moral imbecile was the son of a man of most abandoned character, who in his paroxysms of drunkenness was a savage. I recently discovered his mother in the insane department of a county-house, one of the saddest of dements. The boy's conception, birth, and childhood—his whole history—had been laid in physical disorder, fright, and dissoluteness.

G. L., admitted July 12, 1883: a sweet-faced, intelligent, lovable boy, whose gentle manners instinctively won confidence, and made his new-found friends at the institution believe that the boy had been improperly consigned to our care by a mother too eager to relieve herself of her proper relations to her own child.

The mother's description of this lad (she withheld some points, we afterwards discovered) is so good that I quote here at length: "He is fourteen years old; large, healthy, well formed; kind-hearted, quick-tempered, very dull of comprehension; seems to lack the power of either continued study or labor; full of good resolutions and promises that are seldom kept; determined to see the inside of everything at any cost; fond of working with any kind of tool; fond of little children, and a lover of horses and dogs. A hearty hater of books: can scarcely read, though he has had at least ten months' term at school. Will listen to verbal instruction and ask questions from morning until night. The average child of eight years has better reasoning powers than he." "He is not malicious, but is destructive; is reckless of danger, not regarding consequences, and I am at a loss to decide whether he cannot or will not weigh them. He will both lie and steal, but neither are common practices. When I have found he was guilty of either, I have always found it was done on the impulse of the moment through sudden temptation. *He will not confess.*"

This interesting boy took an upper place at once in our community. Located in one of the best rooms, associated with the best group of boys, his face shining with sweetness, Guy went along swimmingly for nearly three months. Little meannesses were complained of by his associates, and we found that he had few friends among the boys. Notwithstanding his loveliness to us, he was an object of aversion to them. Instances of cruelty to the feebler children, and petty pilferings from his associates' boxes, opened by ingeniously-twisted hair-pins, made numerous counts against him, of which he was generally forgiven because of the lack of clearness in the testimony and his adroit evasions. He devoutly knelt at his bedside every night, was thoroughly up in Romans, Timothy, and the Beatitudes, and stood well in our Bible-class. His troubles with the boys found commiseration from our tender-hearted ladies, so that while in disfavor in the dormitories he was in high favor with the court.

On a quiet Sunday afternoon, when the children were scattered in their various clubs in distant parts of the grounds, excepting that to which G. belonged, our carpenter-shop was discovered in flames. The locked door had been opened by prying, a window was noticed to be partially elevated, and marks of violence upon a tool-chest in which matches were usually kept by the carpenter. Immediately after the fire an attempt was made to sift the testimony of eight or ten feeble-minded boys, the substance of which pointed to one of two or three boys as possibly involved in the incendiarism.

This preliminary examination resulted in placing G. in confinement, with the hope of eliciting from him such confession as might corroborate the circumstantial evidence that pointed to him.

Through three long weeks this sweet-faced, praying, pleading boy held out against all kindness, all persuasion, and we were well-nigh giving up the task, when finally the following letter addressed to his mother passed through our office:

"DEAR MOTHER,—I cannot be satisfied until I tell you what I have done. I am very sorry to tell you of it, but it is better for me to tell it myself. On last Sunday I thought I would like to see how the fire-machines were used, and I got into the carpenter-shop, took a match out of the cupboard, and set the shavings on fire. When the blaze got about a foot high, I hallooed 'fire' before it got too big. I cannot rest until I tell you. Every one treats me too kind to do anything like that in spite to any one. I cannot tell you

how I feel. My heart is like a lump of lead. I am so afraid that you will think I am never going to become a good man. I have asked the Lord to forgive me, and I know he will if I obey him. I have learned the fifth chapter of Romans, and I am going to be a good boy after this," etc.

I found by interrogating the police authorities of his town that he had, prior to his admission to our institution, been shut up for petty larceny, and a late admission came from his mother that he had fired her own house. With these facts before me, I placed him in the House of Refuge, where, two weeks afterwards, it was sincerely believed that the boy had been wrongfully committed, so well had he played his *rôle* of sweetness, and that the confession had been a forced one under the distress of confinement.

The etiological history of Guy is somewhat interesting. The paternal grandmother is described as a fanatic on the subject of religion; the eldest son of this grandmother thinks that he lives without sin, and his brother (this boy's father) is of the same belief, and has been at all times deranged on the subject of religion. The mother's testimony is as follows: "Practically my son might as well have no father, whose only faculties are building engines and studying the Bible. He passes through the world neither seeing, hearing, nor feeling anything that is not directly connected with either of these his two hobbies. Notwithstanding his devotion to Scripture, he is subject to attacks of brutal anger."

Frank L. is thus described on his admission to our school, March 24, 1880, by the teacher in charge: "He is 12 years old, has attended school in winter for the last two or three years, and in summer worked on a farm. Notwithstanding his limited advantages, he can read in the American Third Reader and write an intelligible letter; adds eights, sixes, and fives; can write short sentences; knows the primary and secondary colors; can tell time; draws a little. In form, knows the square, oblong, and circle. Smiles a great deal; is a little deaf. In April he is described as showing much interest in a few simple lessons in botany. Writes short letters, very well expressed. He is a good boy in school."

Scarcely a symptom of intellectual or moral infirmity had been discerned in this interesting boy, when, without known reason, he eloped, which threw our family into great distress, relieved only when writing the father upon the subject, who replied, "I can take no steps towards his recovery: I have already spent hundreds of dollars in bringing him back from just such escapades."

The boy had been committed to us by Judge Ross, of an adjoining county, who found this blue-eyed, sweet-faced lad in the cell of their county prison, beating his head violently against the wall and asserting that he "meant to make himself like his mother, who was already crazy." The sympathetic judge recognized the imbecility of the boy, and refused to pass judgment upon the trivial offence for which he had been arrested.

A few months after his elopement, a newspaper sent to us from Escanaba, Michigan, related the story of a boy who had appeared in that town and who had excited a very great interest.

The boy had been found standing on the shore of the lake, weeping bitterly and explaining to citizens that his father had just thrown himself overboard and drowned. Boat-hooks and fishing-nets were brought into requisition, and for many hours there was an earnest endeavor to recover the missing father, when a more reflecting citizen, upon close interrogation of the boy, discovered that the story was a hoax. The editor of the morning paper took a friendly interest in the boy, and carried him to his office, and explained the case the next morning at great length in a sensational column to be one of insanity from exposure and hardship. The evening paper of a political rival came out with a column protesting that the little fellow was an incorrigible waif from one of the Eastern refuges, and had hoaxed its half-witted contemporary by playing off the insanity dodge.

It proved to be our Frank, for among conflicting statements he had said that he had an uncle near Media, Pennsylvania, which resulted in the return of the boy to our institution, but for a brief season only, for, after six or eight months of diligent attention in school and workshops, and seemingly contented and happy, he suddenly, without known cause, left for parts unknown. After many months he was reported by the police authorities of Chicago, and through the courtesy of these public-spirited gentlemen and of our own police force in Philadelphia, Frank was returned, to come into the office with the same blue-eyed confidence, to settle again at the harness, and with the keenest adaptation to resume his alto horn in the band. Again, without any reason for it that could be ascertained, suddenly and as certainly as before he again eloped, and is at present somewhere within fifty miles of the institution, occasionally appearing to acquaintances quite near us, but mysteriously fading away.

(To be continued.)

NEW YORK PATHOLOGICAL SOCIETY.

STATED meeting, March 9, 1887, the President, T. MITCHELL PRUDDEN, M.D., in the chair.

NUMEROUS SMALL CALCULI IN THE SPLEEN.

Dr. W. H. PORTER presented a number of small calculi, varying in size from that of a

filbert down, which had been removed from the spleen of a man at autopsy. He had counted about one hundred. There were no infarctions and no cardiac lesions. The calculi were scattered throughout the substance of the spleen.

GALLSTONES.

Dr. PORTER also presented some gallstones in a case which suggested the propriety of removal of the gall-bladder, an operation which had been performed nine times, with a bad result in only one.

EFFECT OF ANTIPYRETIC DRUGS ON THE LIVER AND KIDNEYS.

Dr. PORTER also presented the liver and kidneys of a patient who had had a moderate attack of rheumatism. Later, antipyrine was given at rather short intervals for the purpose of reducing the temperature, but it seemed to have had little influence. When the patient entered the hospital the temperature was 105° F., and after antipyrine was given it rose to 107°. Antipyrine was omitted and salicylic acid was given, when the temperature fell to 103°. Antipyrine again being given, the temperature again rose. Antifebrine was also given, but the temperature rose higher and higher, and the patient died with a temperature of 109° or 110° F. In looking over the literature he had found that some men who had experimented with such antipyretic drugs as antipyrine, antifebrine, thalline, etc., had observed the appearance of casts and albumen in the urine, and at the autopsy extensive metamorphosis of the liver and kidneys; but they claimed that this was of no practical importance. Some had also observed that in patients treated with antipyretic drugs, especially typhoid-fever patients, the duration of the disease was longer,—forty-two days instead of about thirty-two days, as was observed when baths and antipyretic measures other than these drugs were resorted to. One writer had said that by the use of antipyrine he had succeeded in getting the highest death-rate, but he was inclined to think that the patients were more comfortable while they lived. In studying the condition of the kidneys and liver in cases in which these antipyretic drugs had been employed, Dr. Porter had noticed in the history that the temperature had been higher than in cases in which such drugs were not employed, and he found a much greater degree of granular and fatty metamorphosis in the liver and kidneys. He had therefore come to believe that antifebrine, antipyrine, and thalline were not as safe drugs as we had been taught. The effect of the increased temperature occurring at some period of the disease after their use was to cause this marked metamorphosis of the liver and kidneys,—primarily of the liver, secondarily of the kidneys.

SYPHILITIC SALPINGITIS.

Dr. H. J. BOLDT presented the tubes and ovaries of a woman illustrating what he believed to be syphilitic salpingitis, as there was no history of gonorrhœa or other cause of the trouble. She had a chancre, and at the time of the operation had well-marked general secondary lesions of syphilis. The intense pelvic pain disappeared after the operation.

PROLAPSED CYSTIC OVARY.

Dr. BOLDT also presented the tubes and ovaries removed in another case for cystic degeneration of the ovaries in a patient who suffered severely from a number of symptoms,—headache, dyspepsia, pain in the back, hypogastric and inguinal pains, dysmenorrhœa, and troublesome cardiac palpitation. It was nearly three months since the operation, and all the symptoms had disappeared except the palpitation, which was somewhat ameliorated. Other treatment had been resorted to before the operation, but without avail.

CARCINOMA OF THE BLADDER.

Dr. FRANK FERGUSON presented the bladder of a man, 61 years of age, who had never had gonorrhœa nor stone in the bladder. He had lost flesh. Micturition was painful and frequent. The steel sound was grasped in the prostatic portion of the urethra. The prostate gland was enlarged. The urine was alkaline, 1014; contained a trace of albumen, and mucus and pus.

The autopsy revealed a tumor at the base of the bladder, involving the entrance of both ureters. The tumor appeared slightly raised above the mucous membrane; was circular in outline, one and one-quarter inches in diameter. The ureters were greatly dilated, and their entrance into the bladder could scarcely be traced through the tumor. The pelvis of the kidneys was dilated. There was chronic diffuse nephritis. The rectum and seminal vesicles were invaded by the carcinomatous growth.

INJURY OF THE BRAIN—RECOVERY.

Dr. JOHN A. WYETH presented the drawing of a piece of fence-rail, measuring in its different diameters two and three-fourths inches, three-fourths of an inch, and one-half an inch, which about four years ago was removed by Dr. Cross, of Alabama, from the brain of a negro, having penetrated the supraorbital plate. The injury occurred from a fall from a moving train. The patient was unconscious after the accident. The eyeball was thrust out upon the cheek. About one teaspoonful of brain-substance was lost. The eye was removed, the patient recovered, and showed no mental symptoms.

Dr. W. M. CARPENTER referred to two similar cases seen by him in the country in boys, both of whom recovered without mental

symptoms remaining, in one the eye being entirely lost, in the other the ball being saved, but sight lost. In both cases the injury was from the kick of a horse.

RECURRING GROWTH BELOW THE EAR.

Dr. DUDLEY presented a small specimen removed from a woman, 28 years of age, who gave the history that about three years ago a physician removed a small growth from below the ear, which was said to be a simple encapsulated fibroid. A year later another physician removed a growth from the same region, consisting of the old cicatricial tissue and some fatty tissue. About one year later Dr. Dudley was called upon to remove the present growth, which seemed to be a simple cyst with its capsule spread throughout the surrounding tissue, closely adherent to the large vessels. It was referred for examination.

LARGE FIBROID OF THE UTERUS—HYSTERECTOMY.

Dr. DUDLEY also presented a solid fibroid tumor of the uterus weighing nine pounds, to which were attached the uterus and its appendages. The patient had complained only of a dragging weight in the back and swelling of the right leg, but an abdominal tumor was not suspected until ten days before its removal, when Dr. Dudley first examined the patient. The operation was performed yesterday. The temperature was below 100° F.

MISPLACED KIDNEY.

Dr. I. VAN GIESON presented the right kidney removed at autopsy from the body of a man, aged 30. It lay in the hollow of the sacrum, its superior apex being on the level of the pelvic brim. Its internal border followed the median line of the body.

GREATLY-ATROPHIED KIDNEY.

Dr. VAN GIESON also presented a greatly-atrophied kidney, the capsule and cortex measuring from two to three millimetres, the cortex consisting largely of glomeruli.

GENERAL TUBERCULOSIS IN AN INFANT.

Dr. W. P. NORTHRUP presented specimens from the body of a mulatto child, aged 2 years, which had been returned to the asylum by the nurse two days before death. It had suffered from repeated convulsions. No diarrhœa; no vomiting. The autopsy showed tuberculosis of the brain, lungs, mesenteric glands, etc., but the spleen escaped. In the cerebellar structure was a large tubercular tumor. The mesenteric glands were very much enlarged, as were also the bronchial. Peyer's patches were considerably ulcerated.

A NEW STAIN FOR MICRO-PHOTOGRAPH SPECIMENS.

Dr. ROOSEVELT presented microscopic specimens illustrating the value of a new stain for micro-photograph work. It was, as far as he was informed, new. It could be made of about one ounce of water to which were added thirty-five drops of a saturated solution of ferrous sulphate. To this add about fifteen or twenty drops of a saturated solution in alcohol of pyrogallic acid. After a while the color becomes a peculiar brownish gray.

NEW YORK ACADEMY OF MEDICINE.

A STATED meeting was held March 17, 1887, the President, A. JACOBI, M.D., in the chair.

BACTERIA IN ICE, AND THEIR RELATIONS TO DISEASE, WITH SPECIAL REFERENCE TO THE ICE-SUPPLY OF NEW YORK CITY: AN EXPERIMENTAL STUDY.

Dr. T. MITCHELL PRUDDEN read the paper, which was based on experimental study by the new method of water-analysis which had to do with its living contaminations: the so-called biological analysis. It was not to be inferred that this method was intended to supersede the chemical. They were in most cases mutually supplementary; but so far as a certain class of diseases which might be transmitted by water, such as typhoid fever and cholera, was concerned, it was safe to say that the biological method was by far the more important. The method was very simple, but it required for its execution considerable patience, care, and experience. The method was briefly described. The following was a summary of his investigations:

If he had accomplished the primary purpose of the paper, he had shown that by the biological analysis of water and of ice we could detect with great certainty the presence of bacteria some species of which could give rise to serious disease, but that, when we had determined the number of bacteria present in water or ice, a careful consideration of other conditions was still imperative in order to determine whether the water or ice was fit for use.

He had shown that the popular impression that water purified itself in freezing was only partly true so far as the bacteria were concerned. The partial purification from bacteria was accomplished not by their expulsion from the water, but by the death of a certain proportion of them; so that, if the bacterial contamination of the water was extreme, or was largely made up of the more hardy species, the ice formed from it, even though quite transparent, might still contain a large number of the living germs.

He had shown that different species of bacteria possessed different degrees of vulnera-

bility to the action of low temperatures. Certain species which were capable of causing serious and even fatal diseases in man—the bacillus of typhoid fever and the common bacteria of suppuration, for example—were capable of resisting a prolonged low temperature with the destruction of a part only of the individuals thus exposed. In the case of the typhoid-fever germs the exposure had lasted seventy-seven days.

He had shown that the resisting capacity of the different species varied with the vitality of the individuals, the degree of temperature, and the time of exposure, and that alternate freezings and thawings sufficed to exterminate completely in a short time all species experimented on, even those which could endure for a long period a sustained low temperature. Data had been gathered which seemed to justify the conclusion that in the freezing of natural waters there might be a purification from bacteria amounting to as much as ninety per cent. We had learned that the effect of freezing on water containing bacteria was comparable to that of filtration, but with this vital difference: that whereas by filtration all forms of bacteria were removed in approximately equal ratio, by freezing, which acted as a sort of selective infiltration, some of the most dangerous forms might be retained while others were destroyed.

He had shown that New York City ice came from a series of naturally excellent lakes and ponds, and from a great tidal river rich in sewage-pollution. He had shown that while the conditions in the upper Hudson did not seem during the ice-forming season to be such as would favor purification from organic matter by oxidation, they did seem to be theoretically—and were shown to be practically—favorable to a considerable degree of spontaneous purification from bacteria by sedimentation; but the limits and extent of this purification were yet to be made out.

Coming to the actual analysis of the ice from both the river and the lakes and ponds, he found a much greater number of bacteria in the snow-ice than in that which was clear or moderately bubbly. He found that the species of bacteria were much more varied and abundant in the river-ice than in that from other sources, while in both there was a considerable proportion of the relatively harmless water-bacteria. He found that while the number of living bacteria varied greatly, not only in different parts of the same block of ice, but also in ice in different parts of the river and from different lakes and ponds, the average number was considerably greater in ice from the river than from lakes and ponds, even when Albany ice, which was worst of all, was excluded from the estimate. He had shown also that the average number of bacteria in ice from all sources taken together was far beyond the general standard which even a moderate degree of purity would allow.

The measures which might be adopted in view of the present condition of affairs were of two kinds: first, such as would come under the supervision of health officers; second, those which belonged in the province of individual consumers.

In the first place, it would seem necessary that the State Board of Health or some other authorized body should be placed in charge of the ice-harvesting fields, and, by a system of inspection not less strict than that which should exist in the case of the ordinary water-supply, determine which, if any, of the sources of ice-supply were so situated as to imperil the health of consumers of ice. In view of what had been seen, this would appear to be comparatively simple in all cases except that of the Hudson River. Here it would be necessary to establish by a most thorough scientific examination the distances from all sources of sewage-pollution at which it might be safely assumed that the water had freed itself from bacterial and other impurities sufficiently to form safe ice. It might in this way be possible to remove any chance of danger by permitting the questionable or bad ice to be sold only for cooling purposes, if such a classification were practicable, and thus not materially interfere with the interests of the ice-companies. A compulsory system of disinfection of excreta in infectious diseases might be instituted.

When we consider the precautions which the individual consumer might adopt, it is evident, from what has been seen, that if he could be certain that his supply came only from the lakes and ponds he would secure for himself a fair degree of immunity from danger. He might avoid ice cut in the vicinity of Albany. Snow-ice should be used only for cooling purposes. A variety of devices might be adopted in the use of ice for the cooling of drinking-water, such as pitchers containing receptacles for the ice, in the cooling of the water in refrigerators, also by making ice artificially from pure water.

REVIEWS AND BOOK NOTICES.

A Text-Book on Surgery, General, Operative, and Mechanical. By John A. Wyeth, M.D., etc. New York, D. Appleton & Co., 1887. 8vo, leather. Pp. 777.

This handsome volume, clearly printed and freely illustrated, is a valuable contribution to the literature of operative surgery. The sections on Amputations, on Ligations of Arteries, and on Hernia have unusually large diagrams of dissections, in which the vessels are colored red and blue to distinguish them more readily. In the chapter on Anæsthesia the preference is given to ether over chlo-

roform, and etherization by the rectum is condemned. Nothing is said about other agents in use for general anæsthesia, such as ethyl bromide, chloral hydrate, or even alcohol. The method of Bonwill by rapid inhalation, and hypnotism for surgical purposes, also deserve consideration. In naming the remedies to be used to resuscitate patients apparently dangerously affected by the anæsthetic, the author omits the use of faradism, nitrite of amyl by inhalation or injection, and ammonia. The contraindications to the use of these anæsthetics, to which Paget and others have directed attention, should also have received consideration, and the preliminary use of atropine to sustain the respiratory function during prolonged operations should be mentioned. The sections upon Regional Surgery are most satisfactory. The last section is devoted to a brief exposition of the clinical and microscopical character of tumors.

A Century of Electricity. By T. C. Mendenhall. Boston and New York, Houghton, Mifflin & Co.; Philadelphia, Porter & Coates. 12mo. Pp. 229.

This book gives a concise history of the development of the galvanic battery, the induction coil, and the main results of the discovery by Oerster of the relationship between electricity and magnetism. One of the best chapters in it is that on "Who Discovered the Electric Telegraph?" and due credit is given to *all* who contributed to the evolution of the instrument, instead of assigning the glory to Morse, as is too often done,—to the detriment of Henry, in particular.

A singular fault in the description of the phonic apparatus is the omission of any reference to Blake, whose transmitter is in general use on all systems.

A condensed description of the development of arc and incandescent lighting and the transmission of energy by electric motors closes the volume. The work is a good one for general readers.

Nervous Diseases and their Diagnosis. A Treatise upon the Phenomena produced by Diseases of the Nervous System, with Especial Reference to the Recognition of their Causes. By H. C. Wood, M.D., LL.D., Member of the Academy of Science. Philadelphia, J. B. Lippincott Company, 1887. Pp. 501. 8vo, cloth. $4.

This timely work upon the semeiology and diagnosis of diseases of the nervous system has its proper field indicated and prepared in the minds of its readers by an introductory section, in which the relation of over-exertion or exhaustion of nerve-cells to organic disorder and physical bankruptcy is insisted upon. Neurasthenia is not, therefore, to be looked upon as a separate disease, but as the result of a strain which is excessive in its relations to the organism which has to bear it. In some it is the expression of premature old age, in the opinion of the author. The various functional and organic Paralyses are discussed in the first section, followed by Motor Excitements in the second. The third chapter is devoted to a consideration of the Reflexes, and the fourth to Disturbances of Equilibration. Trophic Lesions, Sensory Disturbances, Disorders of Memory, of Consciousness, and of Intellection, complete the eleven chapters composing the book, which is replete with information gained from a peculiarly favorable clinical experience and a wide range of reading. The work, however, is not a mere labored compilation, but shows the hand of the skilled diagnostician and experienced physician. It is a compend which should be in the library of every physician.

MISCELLANY.

Jefferson Medical College. — The Sixty-Second Annual Commencement was held April 5, 1887, at noon. Professor J. W. Holland, M.D., delivered the valedictory. There were one hundred and eighty-seven graduates in medicine who had the degree conferred upon them. At the Alumni meeting, on the evening preceding the Commencement-day, Professor Hunter McGuire, M.D., of Richmond, Virginia, delivered the annual oration, and was honored by a reception at the Hotel Bellevue.

The Medico-Chirurgical College held its Sixth Annual Commencement exercises on the 7th instant, Professor P. D. Keyser, M.D., delivering the Valedictory Address to the graduates, who numbered fifteen. The Alumni Oration was delivered by Professor Dudley S. Reynolds, M.D., of Louisville, Kentucky, who was the guest of the Association at a banquet of two hundred covers at the Colonnade Hotel.

State Medical Society of Pennsylvania.—The attention of those members who intend reading papers at the Thirty-Eighth Annual Meeting, to be held at Bedford Springs in June, is directed to the fact that in order to secure a place on the programme it will be necessary to send the titles of their communications as early as possible to the Secretary. Railroad facilities will also be furnished upon application.

"The American System of Gynæcology and Obstetrics," edited by Drs. M. D. Mann, of Buffalo, and B. C. Hirst, of Philadelphia, in four very handsome octavo volumes, will appear shortly, according to the announcement made by the publishers, Lea Brothers & Co., Philadelphia.

JOUSSET, a leader among European homœopaths, gives the following expression to a belief that is in him: "Homœopathy cannot take the place of palliative medication; nor of surgical medication; nor of antidotal medication in cases of poisoning; nor of parasiticide medication whenever clearly demanded; nor of medication by mineral waters; nor of hydrotherapeutic medication; nor of medication by electricity; nor even of empirical medication. Homœopathy is not everything, and liberal medication must include all collateral modes of treatment."—*Medical Age.*

THE GUILD OF ST. LUKE, Evangelist and Physician, has been organized in this country among physicians and medical students who are communicants of the Protestant Episcopal Church. Its chief objects are declared to be to encourage a higher Christian life, to discourage wickedness and vice in the profession, and by avoiding profanity and unclean conversation to encourage reverence for sacred things; also to promote and defend the faith, and to aid in the support of medical missionaries. The entrance-fee is one dollar; annual dues, fifty cents. W. Thornton Parker, M.D., of Newport, Rhode Island, is Provost; Rev. W. F. Morrison, Chaplain U.S.N., is the Secretary.

MEDICAL DEGREES FOR LONDON STUDENTS.—A large meeting of the students of the London Hospital was recently held to discuss the scheme for providing medical degrees for London students. Dr. Langdon Down, in the chair, was supported by Mr. Treves, Dr. Francis Warner, and Mr. Munro Scott (Warden). Mr. F. Treves proposed, and Mr. J. Moore seconded, "That a committee be formed to draw up a petition to the Royal Colleges, praying that they use their best endeavors to obtain the power of granting a degree in medicine, and that this committee take such steps as they may think fit to support this petition." Dr. Warner spoke in support of the proposition, which was carried unanimously. Messrs. H. Smith, Watts, Moore, Taylor, and Rayner were elected on the committee, the latter to act as secretary. The meeting was enthusiastic throughout.

ANTISEPTIC COLLODION.—The *Journal de Médecine* of December 26 contains an account of a new kind of "collodion" which is antiseptic and promotes cicatrization. It does not cause inflammation, and may be substituted for collodion made from gun-cotton in the treatment of wounds and bruises. Like traumaticine, it is efficacious in relieving neuralgic pains and acute or chronic rheumatism. The affected parts should be sponged with it every twenty-four hours, and in serious cases every six hours. If strips of linen or silk be soaked in this collodion, an excellent sticking-plaster is obtained, which quite equals English court-plaster. The following is the formula: Mastic in globules, three grammes; balsam of Peru, one gramme; narcotine, one gramme. Each ingredient should be ground separately, and five grammes of chloroform added thereto.

ADOPTION OF NON-RESTRAINT IN THE STATE LUNATIC ASYLUM AT UTICA.—Dr. G. A. Blumer, the new superintendent at Utica, has inaugurated his official course by abolishing mechanical restraint, resort to which had been steadily decreasing in frequency for some years, under the late Dr. John Gray.

OFFICIAL LIST

OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U.S. ARMY FROM MARCH 27, 1887, TO APRIL 9, 1887.

CAPTAIN JOHN VAN R. HOFF, ASSISTANT-SURGEON.—Ordered for duty at Fort Reno, Indian Territory. S. O. 43, Department of the Missouri, April 4, 1887.

CAPTAIN W. H. CORBUSIER, ASSISTANT-SURGEON.—Granted leave of absence for one month. S. O. 35, Department of Arizona, March 29, 1887.

CAPTAIN HARRY O. PERLEY, ASSISTANT-SURGEON.—Ordered for temporary duty at Fort Maginnis, Montana Territory. S. O. 23, Department of Dakota, March 18, 1887.

CAPTAIN H. G. BURTON, ASSISTANT-SURGEON.—Ordered to Plattsburg Barracks, New York, for temporary duty. S. O. 78, A. G. O., April 5, 1887.

CAPTAIN L. A. LA GARDE, ASSISTANT-SURGEON.—Ordered for duty at Fort Assiniboine, Montana Territory. S. O. 78, A. G. O., April 5, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U.S. NAVY FOR THE WEEK ENDING APRIL 2, 1887.

PASSED ASSISTANT-SURGEON J. R. WAGGENER.—Commissioned a Surgeon on the 18th of March, 1887.

PASSED ASSISTANT-SURGEON H. B. FITTS.—Ordered to the Receiving Ship "Vermont."

ASSISTANT-SURGEON E. C. TRACY.—Detached from the "Vermont" and ordered to the "Atlanta."

PASSED ASSISTANT-SURGEON A. C. HEFFINGER.—Detached from the "Atlanta" and ordered on special duty in connection with construction of hospital at Widow's Island, Maine.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U.S. MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDING APRIL 9, 1887.

URQUHART, F. M., PASSED ASSISTANT-SURGEON.—To assume charge of Cape Charles Quarantine, March 29, 1887.

NORMAN, SEATON, ASSISTANT-SURGEON.—To report for duty at Cape Charles Quarantine, April 2, 1887.

BAILHACHE, P. H., SURGEON.—Detailed as chairman Board of Examiners, to meet in Washington, April 25, 1887. April 4, 1887.

PURVIANCE, GEORGE, SURGEON.—Detailed as member Board of Examiners, to meet in Washington, April 25, 1887. April 4, 1887.

GODFREY, JOHN, SURGEON.—Detailed as recorder Board of Examiners, to meet in Washington, April 25, 1887. April 4, 1887.

IRWIN, FAIRFAX, PASSED ASSISTANT-SURGEON.—To proceed to Baltimore, Maryland, on special duty, April 8, 1887.

PETTUS, W. J., ASSISTANT-SURGEON.—To proceed to Norfolk, Virginia, for temporary duty, April 4, 1887.

PHILADELPHIA, APRIL 30, 1887.

ORIGINAL LECTURES.

CLINICAL LECTURE ON RETENTION OF URINE.

Delivered at the Hospital of the University of Pennsylvania

BY JOHN ASHHURST, JR., M.D.,

Professor of Clinical Surgery, etc.

(Reported by WILLIAM H. MORRISON, M.D.)

GENTLEMEN,—I bring before you today a case of retention of urine, in which I have found it necessary to afford relief by the method described by Mr. Cock as "tapping the urethra at the apex of the prostate gland." I shall take this opportunity of making a few remarks on the subject of retention of urine. Retention must, in the first place, be distinguished from suppression. The latter is a much graver condition, and depends upon some fault in the kidney, either from organic disease or from sympathy with some other portion of the body. As a result the urine is not secreted, and the waste matters remaining in the blood soon give rise to symptoms of uræmia. In retention the urine is secreted but is not passed, and accumulates in the bladder. If there be free secretion of urine, and only retention, the patient may live almost indefinitely, particularly when the retention is of a chronic character, such as we meet with in the case of old persons with enlargement of the prostate. In these cases, retention more or less complete may last for many months. Some years ago a patient presented himself at this hospital, with the statement that his urine was running away all the time. He had been under treatment for paralysis of the bladder. On examination the bladder was found to be greatly distended, the vesical tumor reaching to the umbilicus. There was a certain amount of dribbling, but the bladder had remained full of urine for at least a year. The whole trouble was due to enlargement of the prostate.

Retention of urine may be due to several conditions. It may be the result of spasm. If a person is obliged to hold his water for an unusual length of time, it not unfrequently happens that when he attempts to empty the bladder he finds that he is unable to do so on account of spasm at the neck of the organ. Retention may also depend upon certain general conditions of the system: thus, in typhoid fever retention of urine is a common occurrence. There it is due to the fact that the nervous system, being under the influence of the poison of the disease, fails to recognize the necessity of emptying the bladder. The bladder, under these circumstances, may become much distended and great harm result.

Among the conditions that more commonly come under the observation of the surgeon is what has been termed spasmodic stricture, which is a condition very similar to the spasm at the neck of the bladder already referred to. A person may become chilled from exposure to cold, and when he attempts to pass water finds that he is unable to do so on account of spasm. There is another condition, which is termed congestive retention. Under such circumstances there is probably always some organic change, some stricture, which under ordinary circumstances gives no annoyance; but, as a result of some cause, congestion takes place in the tissues around the stricture, and retention of urine ensues. This appears to have been the condition in the present case. The patient has had a stricture for many years; then, as a result of exposure, there was increased congestion, he was unable to pass his water, and it was found impossible to pass an instrument.

The most important causes of retention of urine are, however, true or organic stricture of the urethra and enlargement of the prostate. It is necessary to distinguish between these, as their treatment differs. Retention from stricture is a more dangerous condition than retention from enlarged prostate. If the patient be a young man, it is probable that the difficulty is not due to enlargement of the prostate, though there may be an acute protatitis following gonorrhœa which may be accompanied by retention. The ordinary form of prostatic hypertrophy is to be looked for in those past middle life. It rarely occurs before the age of fifty years, while stricture is more common between the ages of twenty and fifty years. The age of the patient may therefore enable the surgeon to form an idea as to the cause of the retention. If the retention be not complete or constant, some information may be obtained by observing how the patient

passes water. In stricture, although the urine may be passed in a narrow stream, it is passed with a certain amount of force. The propulsive power of the bladder is not impaired, and the urine may be projected through the stricture even more powerfully than under normal circumstances, in accordance with the law of hydraulics that the force of a stream is increased in proportion to the diminution of the calibre of the tube through which it flows. If there be enlargement of the prostate, the urine will dribble from the end of the urethra instead of being passed in the ordinary parabolic curve. In this condition, the cause of the obstruction involves the propulsive power of the bladder.

The use of an instrument is, of course, the most satisfactory method of determining the cause of the retention. If the instrument be arrested in front of the prostatic portion of the urethra, the obstruction is due to stricture, but if it be stopped in the prostatic portion we know that there is enlargement of the prostate gland. The distance at which the prostate is reached varies in different cases, but the average is six inches. If the obstruction be found at less than six inches from the meatus it is probably due to stricture, but if the distance be more than six inches the prostate gland is probably at fault. As I have already said, it is important to make the distinction between these two conditions, for not only does the treatment vary, but the urgency is also different. If the retention be due to enlargement of the prostate, you may temporize to a certain extent. There is not likely to be such acute distention as will cause rupture of the bladder, and the patient may with safety be allowed to go a certain length of time without active treatment. In stricture, however, the patient is in more imminent danger, and, unless relieved, rupture of the urethra may occur. Rupture of the bladder does not often result from retention due to stricture. If the bladder be distended and the patient receive a blow over the pubes, rupture may occur, and the urine may escape into the peritoneum, exciting peritonitis, or it may be extravasated into the pelvic cellular tissue. If there be simply distention without violence, it is usually the urethra that gives way. The patient, after a violent straining effort, suddenly feels a sense of relief, the urine passes into the cellular tissue, and after a time gives rise to sloughing and gangrene, requiring free incisions to evacuate the effused fluid.

In retention from enlarged prostate it is usually possible to introduce an instrument without much difficulty, if a proper instrument be employed. The physician is apt to use the catheter found in the pocket-case, which, while sufficiently long for ordinary use, is not long enough to reach the bladder in many cases of prostatic obstruction. I have been called some distance into the country to empty the bladder in a case of retention from enlarged prostate, where the whole difficulty was due to the fact that the instrument employed had been too short. Sometimes there is enlargement of the prostate without obstruction. This occurs when the third lobe is not involved. In almost all instances, if the catheter be sufficiently long and of the proper curve, the retention can be relieved. A good plan is to have one of these long English catheters kept constantly over-curved. The catheter must not only be long, but it must be more than ordinarily curved. In order always to have one in readiness, it is well to keep the stilette over-curved. When the wire is withdrawn, the instrument will retain sufficient curve to pass the obstruction. Another good plan is to mould the catheter to the desired curve by placing it in hot water, and then fixing it in this position by immersing it in cold water. It will then keep the curve sufficiently long to permit the obstruction to be passed. There are special catheters made for these cases of enlarged prostate. Some are made with a large curve, while others have a short angular beak, as in this Mercier's or elbowed catheter. This instrument is straight for nearly its whole length, and then has an acute bend. This is sometimes useful, as the sudden rise of the beak enables it to slip over the obstruction.

If you are unable to introduce an instrument in a case of enlarged prostate, it becomes necessary to resort to some operative procedure. Tunnelling the prostate has been recommended. This consists in taking a solid instrument, directing it in what is considered the proper direction, and then forcing it through the prostate gland. This is a dangerous procedure, and apt to be followed by hemorrhage. If you have to resort to any operation, the best plan is to tap the bladder. If the prostate be not large this can be done

through the rectum, but if the prostate be much increased in size it is safer to tap above the pubis. This may be done very conveniently with the aspirator, but this has the disadvantage that the operation will probably have to be repeated as often as the bladder refills. It sometimes happens, however, that within a few hours after a patient has been relieved he is able to pass his water in the natural way. This also occurs after the use of the catheter, and the patient may go a considerable time without again requiring its aid.

Where the obstruction is due to stricture, and it is found impossible to pass an instrument, the urethra may be opened behind the point of obstruction. In this case I tapped the urethra at the apex of the prostate gland. Stricture, as you know, never involves the prostatic portion of the urethra, but is usually seated at the junction of the bulbous and membranous portions. If therefore an opening is made in the urethra at the apex of the prostate gland, you are certain to get behind the stricture. Such an operation is of course not adapted to retention due to enlargement of the prostate, although even there it may be employed to facilitate the introduction of a catheter. In performing the operation, an incision about three-quarters of an inch in length is made in the median line of the perineum, beginning half an inch in front of the anus. The forefinger of the left hand is introduced into the rectum and placed at the apex of the prostate, which can be readily recognized. The knife is then inserted into the incision, with its back towards the anus, and, guided by the finger in the rectum, is pushed onward until its point reaches the apex of the prostate gland. Having reached that point, you cut forward. This opens the urethra, which is at once known by the gush of urine. The knife is then withdrawn and a grooved director passed into the bladder, when, if the opening is not found to be sufficient, it may be cautiously enlarged. An elastic catheter is next introduced upon the director and secured.

The operation was performed in this case five days ago. We shall now remove the tube for the first time, and insert a clean catheter. The urine is beginning to escape by the side of the tube, and in a few days we shall dispense with it entirely. In the course of another week the urethra may be in such a condition as to permit the passage of an instrument, although when the operation was performed this was impossible. If a sound can be passed, we shall be able to cure the stricture by simple dilatation. If we are still unable to pass the stricture, I shall submit to the patient whether he desires an operation for the cure of the stricture, or whether he is satisfied to pass his water through the perineum. Many patients prefer the latter alternative, which is attended with no particular inconvenience. The sphincter power of the bladder is of course preserved, so that there is no incontinence. The only inconvenience is that in urinating the individual must assume a sitting posture. I have had patients who have submitted to an operation for the relief of the stricture, but, finding a tendency to recontraction requiring the constant introduction of instruments, have preferred to abandon the urethra and pass water through the perineum.

The operation which I have described is adapted to cases of retention of urine due to stricture, and not to those due to any other condition. When the retention is due to enlarged prostate, and a catheter cannot be passed, the bladder must be opened either behind the prostate or above the pubis. For the simpler forms of retention from spasm, it is usually sufficient to put the patient in a warm bath and give an anodyne. If this is not successful, a remedy which was formerly much employed may be tried. This is the tincture of the chloride of iron. This has the effect of relieving spasm, and has been found to be very successful. Where you can do it, however, it is always better to relieve the retention at once by the use of the catheter, a soft instrument being preferred. It is not desirable to have the retention last even a few hours, for there is always a certain amount of damage done to the ureters and kidneys even in this short period.

[NOTE.—The perineal tube was permanently removed two days subsequently, and on the thirteenth day a small sound with Thompson's curve (No. 7 of the French scale) was passed through the stricture with very little difficulty, and without causing any discomfort. The patient therefore can, no doubt, be cured by the ordinary method of dilatation, and the perineal wound will close of itself when the calibre of the urethra is restored.]

ORIGINAL COMMUNICATIONS.

REPORT OF A CASE OF INNOMINATE ANEURISM TREATED BY SIMULTANEOUS DISTAL LIGATION OF THE RIGHT COMMON CAROTID AND SUBCLAVIAN ARTERIES—RECOVERY.

Read before the College of Physicians of Philadelphia, March 2, 1887,

BY H. R. WHARTON, M.D.,

Assistant Surgeon, Hospital of the University of Pennsylvania.

I BEG to report the following case, which was operated upon by Professor John Ashhurst, Jr.

Andrew C., aged 42 years, who was born in Scotland and served for a time in the British army, and whose present occupation is that of a gardener, presented himself at Professor Pepper's clinic at the University Hospital with the following history. Eighteen months before his admission to the hospital he began to experience pain running from the throat to the right shoulder and arm, and this continued to be noticed at intervals until six months ago, when he began to be troubled with shortness of breath, and complained of a paroxysmal cough and difficulty in swallowing; at this time he noticed a swelling appearing above and a little to the right of the sternum.

From this time he suffered much from the symptoms above described, and had also great difficulty in sleeping in the recumbent position, and spent large portions of his nights in the sitting posture. The patient had never had syphilis, and the only thing to which he could attribute his present condition was a severe fall upon the right shoulder which had occurred two years previously.

The result of the examination by Professor Pepper was as follows. The patient presented a swelling above the sternum, extending from the middle line two inches to the right along the line of the clavicle. Inspection showed decided pulsation in the swelling, and palpation revealed its expansile character. Auscultation detected no bruit or thrill in the tumor, but the heart-sounds were heard over the area of swelling with great clearness; no murmur was detected over the right carotid or subclavian arteries; examination of the heart showed that its sounds were clear. There was noticed great venous suffusion of the face with distention of the venous trunks when the patient leaned forward. The left pupil was large, the right of moderate size; the right pupil promptly responded to light, the left one acted sluggishly. The radial and other accessible arteries were soft to the feel, so that there was no evidence of wide-spread arterial disease.

As the result of his examination, Professor Pepper was of the opinion that the patient was suffering from an aneurism of the innominate artery.

The case was referred to Professor Ashhurst, and was admitted to the surgical ward.

Professor Ashhurst, after a careful examination of the patient, concurred as to the diagnosis of innominate aneurism, and decided that the treatment by simultaneous distal ligature of the right common carotid and right subclavian arteries was that which offered the most hope of a cure of the aneurism, or at least of benefiting the patient's condition.

On November 13, one week after his admission to the hospital, the patient was etherized, and Professor Ashhurst cut down upon and ligated the common carotid artery just above the omo-hyoid muscle with a catgut ligature; the right subclavian artery was next exposed and ligated in its third part just outside the anterior scalene muscle with a ligature of the same material. The wounds were closed with silver sutures, drainage-tubes being introduced, and were dressed with oiled lint, the whole right arm being wrapped in cotton.

No immediate effect was noticed in the aneurism from the application of the ligature, nor were there any cerebral symptoms. The patient did well after the operation, and upon the succeeding day the temperature and color of the right arm were good. The wounds did well, and in the course of a few days it was noticed that the tumor at the root of the neck had become smaller and firmer and that its pulsations had diminished in force, the dyspnœa and dysphagia had also diminished very markedly, and the patient was able to sleep comfortably in the recumbent posture. Up to the time of his discharge from the hospital, repeated examination failed to discover any pulsation in the radial artery. After this time the patient's improvement was continuous, and he was discharged from the hospital on January 13, just two months after the operation, at which time he was examined by Professor Osler, who made the following report:

"Inspection shows no pulsation visible; right sterno-clavicular articulation prominent. Palpation reveals systolic shock at right sterno-clavicular articulation, and upon firm pressure a feeble pulsation can be felt; this is also noticeable when the finger is placed in the sternal notch. Percussion gives a clear sound beneath the first bone of the sternum until you approach close to the clavicle. There is a small area of dulness beneath the area of prominence. Examination of the heart shows the apex-beat visible just below the nipple; feeble cardiac pulsation felt on deep pressure. No increase of heart-dulness; heart-sounds clear at apex; at second right

interspace, first sound feeble, second sound loud and ringing. Accentuated second sound over first bone of sternum. Over the swelling at right clavicular articulation, first sound is dull, free from murmur, and the second sound is loud. The accentuation of the second sound is heard as far as the middle of the right clavicle; most careful examination fails to discover any indication of murmur."

The treatment of innominate aneurism by the consecutive or simultaneous application of distal ligature to the right common carotid and subclavian arteries has been employed in a sufficient number of cases, and the results following the operation have been of such a nature that it is now established as a well-recognized surgical procedure in the treatment of this affection.

The *rationale* of the treatment of innominate aneurism by the distal ligation of the right common carotid and subclavian arteries is as follows. By the occlusion of the right common carotid and subclavian arteries, if both be tied simultaneously, the amount of blood passing through the aneurismal sac is diminished about two-thirds, and there is a proportionate slowing of the circulation of the blood through the sac; the circulation continuing through the aneurism is, probably, about one-third of the usual amount, representing the blood sent to the large branches given off from the first part of the subclavian. By means of this diminished and retarded circulation we have, in favorable cases, consolidation, to a greater or less extent, of the aneurism, either from the formation of a laminated clot on the inner wall of the sac, or from the extension backward of a thrombus which starts at the site of the distal ligatures upon the carotid or subclavian arteries.

If the ligatures be applied consecutively to the carotid or subclavian arteries, the circulation of the blood-current through the aneurismal sac is diminished to a less degree upon the application of the first ligature. In cases which terminate favorably after this operation, the aneurismal tumor diminishes in size and becomes firmer, the pulsation becomes less distinct, and the pain and pressure-symptoms, if they had previously existed, disappear; that pulsation at the site of the aneurism is seldom entirely wanting is accounted for by the fact that a certain amount of blood still finds its way through the sac to supply the vessels given off from the first part of the subclavian.

The question as to whether it is better to practise simultaneous or consecutive ligation of the carotid and subclavian arteries in this form of aneurism is one upon which the highest surgical authorities hold some diversity of opinion. Mr. Barwell, whose successful cases and writings upon this subject have given a great impetus to the treatment of innominate aneurism by distal ligature, is of the opinion that the most rational form of treatment consists in the application of simultaneous distal ligatures to the carotid and subclavian arteries in properly selected cases.

He opposes the application of consecutive ligatures unless in exceptional cases; and in this opinion he is sustained by Mr. Erichsen, on the ground that by tying one vessel only, time is allowed for the gradual dilatation of the collateral vessels given off from the first part of the subclavian artery, thus rendering the application of the second ligature less effective in diminishing the amount of blood passing through the aneurismal sac.

He concludes that the result of tying the right carotid artery alone for innominate aneurism is not satisfactory, as this vessel has been ligated for innominate or aorto-innominate aneurism thirty times, with twenty deaths; and in case of aortic or aorto-innominate disease it has been tied seven times, and in only one instance has it proved beneficial. He concludes, therefore, that in low innominate aneurism, which almost always involves, to a certain extent, the aorta, it is safer to tie simultaneously the carotid and subclavian arteries than to tie the carotid alone.

Mr. Holmes, upon the other hand, looks with more favor upon the consecutive application of the ligatures; he considers the carotid ligature most important, and recommends its application first, and reserves the ligation of the subclavian for a subsequent period. He is in favor of ligating first the vessel in the direction in which the aneurism exhibits the greatest tendency to spread. He also believes that the distal ligature is efficacious in the treatment of innominate aneurism which is of the mixed variety, which is associated with marked aortic disease; in this opinion controverting the previous teaching that innominate aneurisms associated with aortic disease are unfavorable cases for

distal ligation. In this latter opinion he is supported by the favorable results following the ligation of the left carotid artery for aortic aneurism, as suggested by Mr. Cockle.

So far as I am able to ascertain, consecutive double distal ligation of the right carotid and subclavian arteries has been practised for innominate aneurism (as diagnosed) in eight cases, with three recoveries and five deaths, although there was temporary relief in one of the fatal cases.

I have been able to find the records of thirty-two cases of simultaneous double distal ligation of the right carotid and subclavian arteries for innominate aneurism (as diagnosed), in which the operation was followed by recovery in twelve cases, by death in sixteen cases, and by temporary improvement in four cases. It will be seen that the results of both methods of treatment as regards the number of recoveries is nearly equal, but it must be remembered that the number of cases in which consecutive ligation was resorted to is very small in comparison with that in which simultaneous ligation was employed. I think, therefore, that at the present time the weight of surgical opinion is in favor of the views of Mr. Barwell, that in innominate aneurism the simultaneous double distal ligation of the right carotid and subclavian arteries is both a more efficient and safer procedure than the consecutive ligation of these vessels.

REVIEW OF THE PROGRESS OF MEDICAL AND SURGICAL ELECTRICITY.

BY WILLIAM R. D. BLACKWOOD, M.D.,
Neurologist, Presbyterian Hospital.

ELEVATION OF TEMPERATURE BY LOCALIZED ELECTRIZATION.

At a recent meeting of the Biological Society of Paris, M. Quinquand reported the results of a series of experiments on localized electrization in animals. He claims to have caused decided elevation of general temperature by this method, and so great was the result in certain instances "in increasing the central temperature as to kill the dog in a short time." The form of current used, the strength or duration, were not given (special correspondence to *British Medical Journal*), nor did he state upon how many experiments his deductions were based. Careful repetition of his method has failed in our hands to corroborate the assertion of this gentleman, under any strength of current, either galvanic or induced, within reasonable bounds, whether in man or animals. The *local* rise was of course observed, but under all circumstances the elevation was transient. No general or central heightening was at any time noticed. The applications to animals were possibly not of value, as cruelty was studiously avoided; but in patients, and particularly in personal applications, the utmost bearable limit was reached with the results noted.

A tabular statement of the effect of electricity, both galvanic and faradic, in *lowering* abnormal temperature was included in a review in this journal not long ago,* the experiments being made by the writer.

According to M. Quinquand, the venous blood returning on the side treated contained less sugar than that of the opposite group of muscles: hence he argues that localized electrization would be a therapeutic method of increasing temperature generally, and that many physiological phenomena could thus be studied experimentally. This phase of the matter has not been investigated by the writer as yet, for lack of time, but it will be taken up shortly.

ELECTRICITY IN URINARY DISEASES.

Dr. W. E. Steavenson, electrician to St. Bartholomew's Hospital, contributes an article to the *British Medical Journal* in which he advocates galvanism in nocturnal incontinence of children and in relaxed sphincter of adults. Cystitis also has been benefited by the constant current in his practice, and the ordinary cases of undue frequency of micturition are much relieved by galvanism.

Dr. W. Bence Clarke also gives his experience in similar cases, and adverts to the treatment of gleet by electricity. The reporter called attention to the method five years ago in these pages, in which article the opinion was expressed that electricity is of service in treating inflamed surfaces such as exist in gleet, aside from the fact that stricture almost invariably coexists with chronic gonorrhœa. Dr. Clarke always uses the negative in the urethra, but, al-

* Philadelphia Medical Times, July 10, 1886.

though the writer does so usually, now and then he employs the positive internally. Under such circumstances the urethral rheophore is kept moving slowly from point to point to prevent caustic effect.

GALVANISM IN CHRONIC ULCER OF THE TONGUE.

Meyer recently gave an account of a case in *Berliner Klin. Wochen.* of a badly ulcerated tongue which had resisted treatment for nine years. It was originally caused by biting it during labor. The acute sensitiveness precluded all but liquid diet. One hundred and ninety applications were made prior to cure,—a very large number indeed, when the case is contrasted with those of leg ulcer, which are amenable to treatment in a fifth of the time noted.

In a recent case of the writer's, which resisted strapping, cauterization, and local depletion, with innumerable astringent and other lotions, ten sittings completely cured the patient. The force was twelve to fifteen milliampères.

Since writing the above, a much worse case has promptly recovered under galvanism. The patient was unable to attend to any duty from the pain of the ulcer, but is now on her feet for twelve or fourteen hours daily, although the varicose veins persist.

INDUCTION OF PREMATURE LABOR BY ELECTRICITY.

Dr. Green quotes from Walcher a case needing premature delivery from contracted pelvis, in which a current from ten elements was used,—the positive over the fundus, the negative in the cervical canal. Pains came on at every sitting, and in eleven séances labor set in. Bayer also reports four cases, and Baird, of Albany, reports two hundred and twenty cases. This gentleman employed faradism. He advocates electricity: 1, to modify the pains of labor; 2, to favor more rapid dilatation of the os; 3, to promote more vigorous uterine contractions; 4, to add tone to the abdominal muscles and to increase their working force; 5, to shorten the duration of labor; 6, to insure firm contraction, and thereby prevent post-partum hemorrhage, shock, and exhaustion; 7, to prevent undue expenditure of nervous force in debilitated cases, and thus invite prompt convalescence.

Several years ago the writer called attention to the use of electricity in obstetrics in the *American Journal of Obstetrics*, in which article the above points, with others, were considered and illustrations given of favorable results in inducing labor, in shortening the second stage, in controlling hemorrhage, and in securing rapid involution after delivery. We have found electricity superior to any other method of inducing premature labor from about the thirtieth week in a number of cases in which we assisted professional friends, and induction-currents were always preferable for this purpose. No pains were taken to exclude the fœtal head from the circuit, as Baird asserts to be necessary, because we do not believe that the current takes a straight line between the rheophores, but passes *around* the child through the better-conducting tissue of the uterus, the membranes offering considerable resistance.* Further, we do not believe that, except with extraordinarily skilled practitioners, the vaunted abdominal palpation is of much value, the result of our observations being that in most cases quite prominent gentlemen were mistaken in their diagnosis of the position, as finally proved by the accouchement. Moreover, no current of either galvanism or faradism can injure the child unless it exceed anything bearable by the mother.†

GALVANISM IN SCIATICA.

Dr. W. E. Steavenson gives a *résumé* in the *London Lancet* of sixty cases of sciatica treated exclusively by galvanism. Thirty-seven were cured, eleven were improved, two had returns which were then cured, nine did not continue treatment long enough for a fair test, and one still was ailing. From six to fifteen applications were required to complete the cure.

GALVANISM IN RECTAL STRICTURE.

Mr. Whitmore read a paper on this subject before the West London Medico-Chirurgical Society recently, giving notes of several cases thus treated, and he expressed great satisfaction with the results. One instance, in which two years' dilatation with bougies failed to alleviate, and in which the symptoms were alarming, was cured in three months under electricity. The method of operating was not stated.

It is singular that this has hitherto been untried in this affection, in view of the

* Medical Bulletin, May, 1885. † Ibid.

great service resulting from electrolysis in urethral stricture. How galvanism will act in stricture of the œsophagus is probably unknown: at least the writer is not aware of any reported cases. In the only one tried by himself the current could not be borne by the patient,—a delicate though not nervous lady,—even as low as three milliampères.

GALVANISM IN EXTRA-UTERINE PREGNANCY.

Dr. A. H. Goelet gives in the *New York Medical Journal*, December 6, 1886, notes of a case of extra-uterine gestation in which arrest of the pregnancy and dispersion of the resulting foreign body were produced by galvanism. The operation was done by Dr. Rockwell at three months, and was repeated twice more. Twenty cells were used (current-strength unknown), and for ten minutes each time. Relief from the characteristic suffering was secured at once at the first sitting, and in five months thereafter the tumor was scarcely perceptible to the touch. Galvanism was repeatedly used during this time, to insure absorption. The diagnosis appears from the description to be assured, and Dr. C. C. Lee coincided with Drs. Goelet and Rockwell in this view, after several consultations.

Dr. Aveling, senior physician to the Chelsea Hospital for Women, gives in the *British Medical Journal* notes of a case of extra-uterine gestation treated by faradism at the third month. Gaiffe's apparatus was used on four succeeding days, the tumor being clasped between an intra-vaginal rheophore and another over the abdominal parietes. The duration of each application was only ten minutes, and the current-strength was comparatively small, except during the last thirty seconds. The case was seen by Mr. Wrench, a surgeon of Baslow, and Sir Spencer Wells, and the diagnosis was confirmed by each. Two months afterwards the tumor was deemed encapsuled, but it was not reduced in size. Menstruation had been resumed, and the signs of pregnancy had disappeared.

Another case of ectopic gestation was reported in the same journal by Dr. Richard Petch, physician to the York Infirmary, in which galvano-puncture was employed.

In the debate upon the subject before the Obstetrical Section of the British Medical Association, at which a number of cases were referred to, Mr. Lawson Tait admitted his inability to diagnosticate extra-uterine pregnancy prior to rupture of the sac, and denied the ability of any one to make the discovery; but he was promptly met by our distinguished friend Dr. H. A. Kelly, of this city, who instanced one of his own cases in which a subsequent laparotomy confirmed the diagnosis. Now that the efficacy of electric treatment is abundantly manifest in rescuing the unfortunate mother from an almost certain death, despite the croaking of malcontents, claims of priority in thus operating are springing up all over the continent; but there is no doubt that Dr. Allen, of this city, was the first to demonstrate the procedure practically, just as Dr. Kelly has clinched the question of ability in the way of diagnosis. Philadelphia doctors are coming to the front, as their *confrères* the lawyers did some time ago.

With the experience gained from the treatment of five successful cases, I am surprised that any distinguished teacher should consider the diagnosis impossible or even difficult, or that doubt as to the method of operating should exist. That the strongest faradic currents obtainable from medical coils, when confined to the necessarily small area of the pelvis required, can injure the mother is to me inconceivable, yet the tetanization of the fœtal mass and its disintegration by the rapidity of the interruptions of current would inevitably destroy it. To do this also we must rely upon powerful currents *long continued*, and not risk the grave chance of rupture by spreading the treatment over a week, as is often done. *So much* current will destroy the embryo. Give *that much at once*, and keep it up for an hour at least. When assured of the fœtal death, then rely upon galvanism to disperse the tumor, which is an assured success, so far as I know from careful study of all recorded cases and knowledge of some not yet reported.

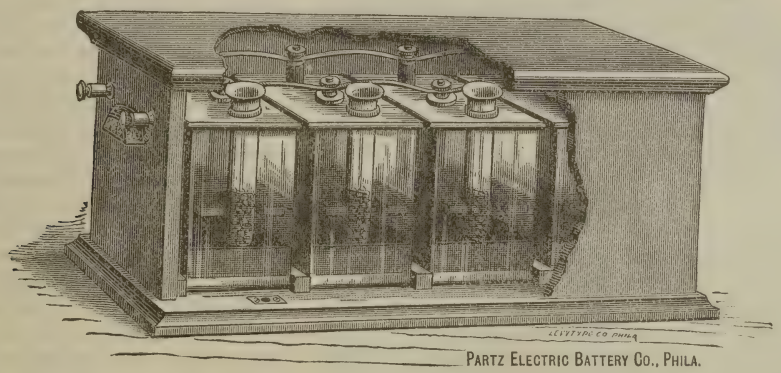
The case reported last summer by myself is now entirely well, and the mass was undiscoverable by the most careful examination after four months. Galvanism was used two or three times a week during this time.

FARADIZATION IN JAUNDICE AND HEPATIC TORPOR.

Dr. Henri Secretan stated to the Geneva (Switzerland) Medical Society the history

of a child affected with catarrhal jaundice. Before employing electricity various cholagogues were tried without avail, and the flow of bile was induced in three sittings of ten minutes each. One rheophore was applied over the site of the gall-bladder, and the other in the rectum.

In a series of articles on "Electricity in Abdominal Disorders,"* I have called attention to the efficacy of both galvanism and faradism in torpidity of the portal circulation, and a reference was made to the use of static electricity in sluggish liver. Since that time many cases have been treated by static electricity, and I am now of the opinion decidedly that no better agent exists as a cholagogue. Those who do not possess a static machine can depend upon faradism, however, and it is unnecessary to traverse the length of the bowel, as above stated, with any form of current. By applying the rheophores so as to include the liver in varied axial lines, thorough stimulation is insured, provided, of course, that patency of the ductus communis exists. Relief to many cases of congested hemorrhoids has thus been assured.



PARTZ ELECTRIC BATTERY CO., PHILA.

ELECTROLYSIS IN LUPUS VULGARIS.

Gärtner and Lustgarten have reported ten cases of lupus treated as follows, with good results. Instead of using needles for puncture, as usually done, they employ a flat silver rheophore, slightly curved and encircled by a vulcanite ring. The plate is recessed a trifle, in order to keep it from touching the sound skin, and the elevated nodules alone are pressed upon. This arrangement is attached to the negative pole, and the other to any near indifferent point. Up to ten milliampères is directed for fifteen minutes or so, and the part is dressed with iodoform. The leathery scab falls in about fourteen days, and leaves a flexible pigmented cicatrix. The procedure is painless. A better material would be zinc in place of the silver, as its caustic effect is greater.—*Wiener Med. Wochenschrift*, xxvii., xxviii., 1886.

GALVANO-PUNCTURE IN CERVICAL ADENITIS.

The galvano-cautery has been used by Professor Dumenil, of Rouen, in a number of cases of scrofulous enlargement of the cervical lymphatic glands. A platinum wire was heated after introduction, without anæsthesia, and little scar resulted. Suppuration ensued in a few cases, and all were rapidly resolved by the measure. As caseous cervical glands are foci for further involvement of visceral glands in tuberculosis, the destruction of them is not only a question of relieving deformity, but an important prophylactic measure.

GALVANO-PUNCTURE IN GYNÆCOLOGY.

Apostoli formulates as follows in gynæcological operations by electricity:

1. In treating either the uterine parenchyma or the periuterine cellular tissue, great care is needed to avoid the peritoneum in the puncture.
2. Drainage should be facilitated if suppuration ensues or is anticipated.
3. The punctures should not exceed five or ten lines in depth.
4. The bladder should be avoided carefully.
5. In all cases of lateral or posterior puncture the localities of arterial pulsa-

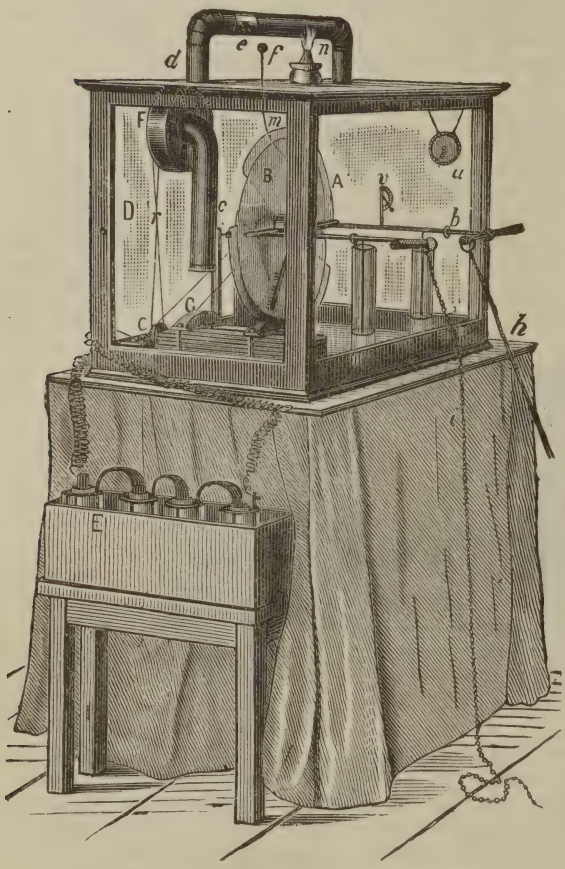
* Medical Bulletin, October, November, and December, 1884.

tion should be accurately determined and all large vessels avoided.

6. Rest in bed must be enforced for several days in all cases.

7. Antiseptic injections precede and follow all operations, and iodoform gauze tampons are habitually applied to all punctured points until complete closure ensues.

8. Sexual intercourse is prohibited until the cure is thoroughly assured.



Static Electrical Machine, with Hot-air Attachment.

GALVANO-CAUTERY IN HAY-FEVER, SNEEZING, AND ASTHMA.

Dr. F. De Haviland Hall describes a series of cases in the *London Lancet*, in which this method of treatment was successful. One lady, who had previously aborted whilst pregnant from uncontrollable sneezing, was carried safely to term by reducing a hypertrophied mucous membrane over the right inferior turbinated bone. Two cauterizations a fortnight apart sufficed. Dr. Hall also found a similar procedure serviceable in hay-fever, and anterior hypertrophies of the Schneiderian membrane in some cases of asthma. Local anæsthesia by cocaine was employed in all cases satisfactorily. We have found, during the summer, good results in two cases of the so-called "rose-cold" from light searing by the electric cautery.

NEW AND IMPROVED APPARATUS.

In our notice of the improvement in gravity cells by the Partz Electric Company in the *Times* of November 13, 1886, pressure on our columns permitted the introduction of one cut only. The cell illustrated was one with slotted cathodes, and is that intended to substitute the Leclanche, but the reference was to the new acid gravity, which is shown on page 501.

An ingenious method of insuring prompt action of static machines in murky weather is that now a favorite in France, where much more attention is paid to this form of electro-therapeutics than is done with ourselves. The air within the case is not only kept dry, but it is *warmed* to any desired temperature by maintaining its circulation through a tube in connection with a rotary fan-wheel. The two ends of the tube are within the case, but at a part which is exterior to it an alcohol-lamp heats the air as it passes. The fan, together with the rotating plates of the machine, is driven by an electro-motor, which is in turn energized by four Bunsen cells. Messrs. J. W. Queen & Co., of Philadelphia, are agents for the apparatus.

A NOTE ON THE IRRADIATION OF MOTOR IMPULSES.

Read before the College of Physicians of Philadelphia, March 2, 1887,

BY N. A. RANDOLPH, M.D.,
Professor of Hygiene in the University of Pennsylvania.

ABOUT two years ago this question arose in my mind: If a man perform work with the muscles of (*e.g.*) his

right hand exclusively, and to the point of fatigue, can he thereafter perform as much work, of the same nature, with the left hand as he could if the right had not been previously exercised?

It will be seen that this question relates in no wise to a comparison of the work of the two hands, but to an examination of the work which may be accomplished by one hand, as conditioned by the previous exercise or non-exercise of its fellow of the opposite side.

It is evident that the answer to this query is dependent on intracranial processes solely, and that such answer would throw some light upon the functional independence or interdependence of the two halves of the brain.

In order to answer the question just stated, certain conditions are prerequisite. The subject of experiment must have no conception of the object of the investigation, or he will unconsciously become a partisan of one or the other hand. He must also have a very strong inducement to exercise his volition to the utmost.

These conditions were fulfilled in the persons of some intelligent and vigorous convicts in the Eastern Penitentiary in this city. The stimulus was a money-prize to the man who accomplished the most work in a given time. In the prosecution of these experiments I am under obligation to the courtesy and assistance of Dr. W. D. Robinson, physician to the Penitentiary.

In the first series of experiments rubber-bulb syringes, identical in all their measurements, were used, and the amount of water which the men could transfer from one vessel to another in a given time was accurately measured and taken as proportionate to the work performed. Some forty observations were made by this method, with the uniform result that either hand could do more work when its exercise preceded than when it succeeded the similar exercise of its fellow of the opposite side. It was found, however, that the muscular effort could not be entirely restricted to one side of the body in this method, as great fatigue was always accompanied by a grimacing and writhing which implicated the muscles of both sides of the face and trunk.

A Morse telegraph was next used, the muscular movements in this case being restricted to an up-and-down motion of one finger of each hand, the number of such movements made in a given time being recorded on the usual long and narrow strip of paper as dots or dashes in accordance with the celerity of contraction and relaxation of the flexors of the finger. The results of this series of experiments were uniformly confirmatory of those before obtained, but the method had to be abandoned as productive of great eye-strain in counting.

I then had made the instrument which is here shown. It consists simply of the clockwork and dial of an ordinary gas-meter, to which a lever is adapted in such wise that each flexion of the finger is recorded by an appropriate motion of the index on the unit-dial. The apparatus is fixed in a box, upon which the hand and forearm may conveniently rest. The lever projects through an aperture in the lid, and a glass plate in the side permits the records on the dial to be easily read off and noted. Six healthy prisoners, supplied with the incentives of cash and competition, were repeatedly examined by this means. To each fifteen minutes were given to make the best record he could with (*e.g.*) the right forefinger, and thereafter the left forefinger was similarly exercised for the same time. On the following day the same process was repeated, always commencing, however, with the finger of the hand which had been used second on the previous occasion. No hand was ever thus employed twice on the same day.

The results were practically uniform. The man who for fifteen minutes flexed and relaxed his right forefinger with the greatest speed possible to him would, on the following day, accomplish on an average nearly ten per cent. less work with that finger when its exercise was consecutive to a similar exercise of the forefinger of the opposite side than when its work was initial.

Usually, more work could be accomplished by the simultaneous exercise of the two forefingers than by their exercise one after the other. In such exercise of both hands at once, and apparently from some unconscious effort at rhythm on the part of the subject, it was noted that the movements of the left forefinger were generally more active and rapid than when used alone, although in both instances the greatest effort at speed was evidently made. I am told that some pianists have a similar experience, inasmuch as they find it pos-

sible to exercise the fingers of the left hand more rapidly when the right is similarly engaged than when the right is inactive.

The relation of these facts to the observations of Dr. S. Weir Mitchell and Dr. Morris Lewis is largely supplemental in its nature. These observers, as is well known, showed that the knee-jerk is reinforced by any voluntary movement in any part of the body, and that this reinforcement was apparently due to such an irradiation of motor impulse from the active centres to other similar centres as placed them and their related muscles in a condition of heightened responsiveness to external stimuli. My studies not only tend to confirm these observations, but to show that the fatigue of one centre may induce a sympathetic fatigue in other centres.

These observations are of interest, inasmuch as they suggest that the centres for volition, attention, and co-ordination (or one or more of these) are not, in their functional activity, bilaterally symmetrical and independent, — that is, that these functions have not attained complete differentiation into right and left will, attention, or co-ordination; that probably the first effect of the voluntary activity of a portion of one cortical motor area is a stimulation of the corresponding portion of the other hemisphere, a stimulation that may result in its slightly premature fatigue; that apparently more work can be effected through the voluntary simultaneous exercise of two such portions of the motor apparatus than by their independent exercise, one after the other.

CASES PRESENTING PECULIAR MANIFESTATIONS OF MALARIA.

BY V. M. REICHARD, M.D.

IN the following cases the curability by quinine is considered as proof of the malarial nature of the disease. The cases belonging to the first series were treated in February and March, 1886; they were characterized by a peculiar temperature-record.

Case I.—Male, æt. 10. Health previously had always been good: now complained of what was considered a bad cold. Saw him on the second day in the evening, when his temperature was 101.5°. He had a harsh, irritating cough, with no expectoration; râles were heard over both lungs; pulse full and bounding; eyes injected, and lids somewhat swollen; bowels sluggish, and tongue slightly coated. Prescribed cathartic and nauseant expectorant. Next morning his temperature was 101°; the other symptoms were unchanged, except that the bowels had been pretty freely opened. So he ran on for several days, but without improvement. On examining his tongue more closely, I thought I noticed a condition which I have learned to associate with malarial fevers. The tongue was pretty well covered with a tough, white coating, except near the end, where it had very little if any coating. Through this the papillæ stood out prominently. Having failed signally in treating the "cold," I concluded to try the effect of quinine, and accordingly gave him twelve grains in solution; next day, ten; third day, five; continued at this daily dose for a week. After the first day his temperature remained normal, and he was up and about on the second day.

Case II.—Mrs. W., mother of Case I., æt. 35, of phthisical tendency. In the spring of 1884 she had a severe attack of catarrhal pneumonia, which left a slight impairment of left apex. The day her son first got up she went to bed, with pain in left mammary region and a temperature of 101°. Her cough was severe, with some mucous expectoration. I thought that I detected crepitant râles and beginning dulness over lower lobe of left lung, and instituted appropriate treatment. Saw her in the evening in very much the same condition: temperature still 101°. On the next day, as I could not find any adequate chest-symptoms, in lieu of something better I gave her twenty grains of quinine, with the result of clearing up the case. Under the regular use of quinine she made a perfect recovery, and has been in better health ever since than she had been at any time after February, 1884, though she was under great mental excitement while convalescing.

Case III.—E. W., youngest son of Mrs. W., æt. 4, was a bright, robust lad, who spent most of his waking hours out of doors, the type of a healthy country child. Went to bed the day his mother began to convalesce; saw him at 9 A.M. Except slight nervousness, he did not seem to be at all sick, and it was remarked by his parents and the nurse that it was his wish to be in bed with his mamma more than illness which kept him in. Ordered a mild laxative. At 4 P.M. he was taken with a convulsion, the most terrible it has ever been my lot to witness. Consciousness did not return until 10 P.M. He passed a moderately good night. Next morning the temperature was 102°, an uncontrollable diarrhœa set in, and he died in the evening, less than forty-eight hours after his first complaining. No post-mortem.

Case IV.—H. G., male, æt. 3, for several

weeks had been affected in an anomalous manner, now better, now worse; at no time much fever, and *at no time any periodicity*. This latter fact was noted in all this series of cases. There was not as much variation of temperature as in an ordinary case of typhoid fever. After having exhausted my resources and the patience of the family, I gave him quinine as an antimalarial, and the result was all that could have been wished.

Case V.—Male, æt. 12; was ill for several days. Evening temperature never above 103.5°; morning, never below 103°. In the light of the preceding cases, put him on quinine. As his stomach was irritable, mixed it up with an equal weight of chocolate. The case also promptly recovered.

These cases all occurred within a period of ten days, and all within a radius of one-eighth of a mile. Aside from the peculiar aspect of the tongue I have mentioned, there was nothing to indicate a malarial *element*, to say nothing of a malarial *cause*. Above all, there was no element of *periodicity*, which is regarded as so essential a feature of the continued malarial fevers.*

The next series of cases was also peculiar.

Case I.—J. W., male, æt. 4. When two years old, several lymphatic glands in the neck suppurated and were discharged. Was well up to August, 1886; then had enlargement of the cervical and submaxillary lymphatics. Put on treatment, with negative results. Seemed to be some periodicity in his malaise, but no distinct febrile exacerbation or remission. He was cured at once by quinine. Never had malarial fever.

Case II. and *Case III.*—Were sisters, who had long been subjects of malarial paroxysms, though they had had no attack for nearly a year. About the same time both were affected as Case I.,—decided glandular enlargement without any tendency to suppuration. It yielded at once (within thirty-six hours) to quinine. Both ladies were of strumous type.

Case IV.—M. T., female, æt. 20. About four years before, a horse had fallen on her and injured her left tibia; afterwards she had considerable trouble with it. In December, 1884, I had incised it, evacuating a small amount of pus, with the result of putting the leg in better condition than it had been since the accident.

In December, 1885, she began to have severe pain in the limb. Counter-irritation relieved it for a time. Pain would recur in spite of all treatment. As the attacks of pain seemed to recur at regular intervals, I put her on large but gradually diminishing doses of quinine. Recovery perfect. About six months afterwards had slight recurrence, but did not see her; she sent for some of the solution of quinine and was relieved. At no time was the temperature above 99.5°. Had never had malarial fever.

The only explanation of these cases I am prepared to offer is that the dose of the malarial poison was too small to cause a distinct outbreak. As a chain is no stronger than its weakest link, so the weakest local point in all four of these cases was the first to suffer. This is the only way in which I can conceive of these cases being malarial, but that they were so I am fully convinced. Cases II. and III. expressed a belief that they had malaria, knowing the sensation from prolonged experience in former years. None of the last series had a temperature above 100° during their treatment.

Fair Play, Maryland.

* Sternberg's "Malaria and Malarial Diseases," p. 209. (William Wood & Co.)

TRANSLATIONS.

Iodoform in the Treatment of Gonorrhœa.—In an interesting communication to *Le Progrès Médical* of March 5, 1887, M. Thiéry extols in high terms the use of iodoform in the abortive treatment of gonorrhœa. He states that he feels a certain timidity in presenting a new therapeutical agent for this most troublesome disease after so many others have been tried, accepted, and rejected; and yet, impressed with the fact—based upon the researches of Neisser and others—of the microbian origin of the disease, he was surprised that among all the antiseptics employed, such as corrosive sublimate, carbolic acid, boracic acid, resorcin, etc., iodoform should not have been included,—an antiseptic used daily in the practice of surgery.

Corrosive sublimate coagulates the albuminoids, forms non-antiseptic bases with them, and thus exerts but a passing and superficial influence upon the germs. Nitrate of silver acts upon the microbes, but at the same time seriously affects the mucous membrane. Iodoform, besides its antiseptic value, is readily absorbed wherever the mucous membrane is denuded, and is also decidedly analgesic,—two important qualities which adapt it specially to the treat-

ment of gonorrhœa. Its odor can easily be disguised by a little oil of eucalyptus, vanilline, etc.

The purpose of the abortive treatment of gonorrhœa at the present time is to destroy the gonococcus. This accomplished, the inflammation will readily subside with appropriate measures. In an examination of thirty-eight cases it was found that in the pus passed during the period from the first to the fifth day the gonococci were comparatively few in number. They increased from the fifth to the fifteenth day. The maximum was attained from the eighth to the tenth day, while after the fifteenth day they began rapidly to decline, sometimes remaining, however, as late as the end of the third week. These figures are important as showing the most favorable time for the use of the antiseptic injection. Antisepsis will be best accomplished during the first four days.

M. Thiéry reports six cases treated with the iodoform injection with the most gratifying results. In his *résumé* he states that as to iodoform-intoxication it seems impossible. In the employment of iodoform alone, its elimination can easily be verified by an examination of the urine. In one case only did the patient complain of the taste of iodine in the mouth. Its presence in the saliva could never be detected by means of the test. In its use there were no other uncomfortable sensations, and yet as many as twenty-nine injections had been given in a period of twenty-eight days. On the other hand, its action is safe, rapid, and positive, the microbes quickly disappearing, sometimes being entirely absent by the eighth day.

As failure in the treatment of gonorrhœa occurs usually on account of the patient's ignorance in managing the injection, M. Thiéry recommends that the physician always attend to this part of the treatment himself. He uses as the injected material iodoform *porphyrized* as completely as possible, and simply suspended in the oil of sweet almonds. Before making the injection, the urethra should be gently washed out, to remove as much of the pus as possible. Micturition just before the injection is the best means of accomplishing this result and avoiding any backward flow of the pus into the bladder. The olive-shaped nozzle of the syringe should be introduced just within the meatus. About two grammes of the liquid is then thrown into the urethra, and retained there by the patient holding his finger over the meatus for about twenty minutes. A strict and temperate diet should be used during the period of the injections.

Some Recent Studies upon the Bacillus Typhosus.—At a recent meeting of the Société Médicale des Hôpitaux, M. Chantemesse presented some interesting statements of the result of his studies, in company with M. Widal, upon the bacillus typhosus—the bacillus of Eberth and Gaffky. It is enlarged at the extremities, extremely mobile, and offers strong resistance to the usual modes of staining. It can be developed in meat-broths, better in gelatin, but best of all upon the potato, upon which it shows itself as a moistened thread after three days, sometimes not until after fifteen days. Slowness of development is specially characteristic of this bacillus. Reproduction takes place readily in pure water, especially if the water be sterilized. It resists cold, and will endure a temperature of 45° C. without perishing. It is destroyed by a temperature of 80° C., as well as by boiling for several minutes. It increases more rapidly in a moist than in a dry soil. As to the action of antiseptics upon its vitality, a $\frac{1}{20000}$ solution of corrosive sublimate will prevent its culture; a $\frac{1}{800}$ of sulphate of quinine will produce the same effect; while the $\frac{1}{400}$ of carbolic acid will have no effect at all upon its multiplication in a culture-fluid. By adding a two-per-cent. solution of hydrochloric acid to the culture the growth of the bacillus is retarded, but it does not die, for, on dropping a little of the fluid containing it into an alkaline broth, it will begin again to multiply with all its original vitality.

A propos to this subject, it is to be noted that M. Dujardin-Beaumetz read a report before a recent meeting of the French Academy of Medicine, in which, after stating the methods of M. Pecholier to jugulate the course of typhoid fever simply by means of quinine and tepid baths, he expressed the hope that the day would soon come when, after a better knowledge of the bacillus typhosus, we shall be able to possess an attenuated virus, permitting us to realize all the expectations now founded upon the proceedings of Pasteur.

PHILADELPHIA
MEDICAL TIMES.

PHILADELPHIA, APRIL 30, 1887.

EDITORIAL.

RECTAL INJECTIONS OF CARBONIC ACID GAS FOR PULMONARY DISEASES.

WHEN a new remedy is brought forward or a novel treatment advocated for that opprobrium of medicine, pulmonary consumption, there have never been wanting in its support the reports of cases which have had cough and expectoration reduced, night-sweats checked, and appetite improved, and which have experienced a proportionate gain in flesh and strength. That such results have been actually obtained from various and very diverse plans of treatment cannot be controverted: the files of medical journals contain hundreds of such reports contributed by men whose names are sufficient warrant for accepting the facts just as they are stated. It follows, then, logically, that the beneficial action which is claimed for each, but is exerted by all, cannot be the exclusive property of any. The influence of the mind over the body, especially the therapeutic value of hope, has a better field for demonstration in phthisis, probably, than in any other disease. Moreover, in instituting any plan of treatment the intelligent physician, as a matter of course, also corrects to a greater or less extent the hygienic faults in the mode of life, and this in reality is often of greater remedial value than the medicines which he prescribes with such confidence.

We make these remarks because we consider that these facts should be kept in mind when any new expedient is submitted to the profession for the treatment of consumption. Owing to a peculiar combination of circumstances (in which politics was not entirely absent), reports of the Bergeon method of treating phthisical subjects, which had been for a short time on trial at the Philadelphia Hospital, were prematurely published, with some embellishments, in the daily press, and it was widely heralded as a specific for consumption. Public interest was immediately excited to a remarkable degree, and it at once became a popular and all-absorbing topic for conversation in ball-room and barber-shop, in parlor and kitchen. It percolated into the country papers, and inquiries began to pour in with regard to the so-called "Philadelphia treatment" of consumption. Even the Sunday papers contain large illustrated advertisements of the manufacturers of the new apparatus for the administration of gas. There is evidently now a popular craze upon the subject, which will doubtless be utilized by some members of the profession so as to reap a rich harvest from it while it lasts. But we have sufficient confidence in the intelligence and honesty of the mass of the profession to believe that extravagant hopes will not be encouraged, and that patients will be told that, while some of the symptoms may be relieved by carbonic acid gas, the method is still in its experimental stage, and is by no means a specific, or even certain in its beneficial action. The results which have been claimed for it can be obtained and have been obtained by other means of treatment which have stood the test of experience and are already the property of the profession. Moreover, advices from Paris inform us that the interest there is declining, and that Germain Sée has abandoned this method because the results have not been satisfactory.

The evil following from the manner in which the treatment has been brought before the public is evident in two directions. In the first place, the impression is given that the profession would not so eagerly seek a new treatment if the methods in common use hitherto yielded satis-

factory results. When the reaction comes, —as soon it must,—the confidence of the public in our therapeutical resources will therefore be severely shaken. In the second place, phthisical patients now are not satisfied that everything has been done in their behalf unless they have had their bowels *secundum artem* inflated with gas. If the judgment of the physician condemns this procedure and he refuses to employ it, he runs the risk of either offending his patient or seeing him go to the specialist of the syringe, whose scruples do not interfere with his practice. Would it not be well if our medical societies would take up the ethics of this practice for consideration?

SO-CALLED SURGICAL SCARLATINA.

SINCE Paget in 1864 called the attention of the profession to the scarlatinoid eruptions which occur after injuries and surgical operations, these exanthems, long before observed and occasionally referred to in medical literature, have been the subject of especial study. In England, Jonathan Hutchinson, Hilton, Bryant, Sterling, Goodhart, and others; in France, Trélat, Germain Sée, and Tremblay, have reported cases. In this country, Atkinson made these rashes the subject of an admirable paper read before the American Dermatological Association last year. This observer regards the following conclusions as justified by the facts thus far accumulated:

1. Unprotected persons who have suffered injury or have undergone surgical operations are rather more liable to scarlatina than the unprotected healthy. This increased liability is probably due to diminished power of resistance to disease, and will probably hold with regard to other specific fevers. Scarlet fever is more apt than the other exanthemata to attack such persons, because its influence is usually more wide-spread, and because it varies within such wide limits that it often escapes the attention of those who readily detect other infectious disorders and provide against them.

2. When an epidemic tendency on the part of these eruptions to prevail after injuries and operations is shown, it may be concluded that true scarlatina is present.

3. Septicæmia is occasionally accompanied by a scarlatiniform rash which does not depend upon the scarlatinal poison.

4. Medicinal eruptions, especially those caused by cinchona and its preparations, not infrequently follow injuries and operations. These rashes are often erroneously attributed to true scarlatina and septicæmia.

Quite recently, Hoffa, of Würzburg (*Volkmann's Klin. Vorträge*, No. 292), has gone over the whole subject with great care, both from the clinical and from the bacteriological point of view. He concludes that if the term surgical scarlatina is to be retained at all, it must be restricted to those cases in which the scarlatinal infection has actually taken place by the way of a wound, and that all the other forms of erythema occurring after injuries and surgical operations, which have nothing in common with scarlatina but their color, and which comprise a very large group of the cases, must be designated according to their etiology. In the absence of the concomitant symptoms of scarlet fever, isolation is not required.

THE MECHANICAL TREATMENT OF LUMBAGO.

IN no class of cases is the aid of physiological or so-called mechanical therapeutics more welcome to physicians than in the treatment of chronic muscle- and joint-affections, which are the despair of ordinary therapeutics. Massage, hydrotherapeutics, gymnastics, have a field of usefulness that is second to none in the

relief of disorders of nutrition. It is with pleasure, therefore, that we direct attention to a lecture* which we have just received, in which the successful treatment of lumbago by systematic exercise is demonstrated, and descriptions with illustrations of the simple forms of apparatus employed are given. Dr. Schreiber claims that his experience has shown that every case of lumbago, acute as well as chronic, can be completely cured by mechanical treatment. On the contrary, rest and antiphlogistic applications intensify the affection, increasing the pain and the functional disorder. The apparatus required for the treatment is easily made, and the want of it should not be allowed to interfere with a trial of this method in any given case. Of course the tendency to return will remain, but it cannot become developed if the ordinary means for the prevention of so-called muscular rheumatism are employed by the patient. Among the prophylactic measures of most value we may name due attention to the renal functions, systematic exercise, and the wearing of the abdominal flannel bandage, or "cummerbund," which we have found especially useful.

As some cases of myalgia have been shown to be due to trichinosis, it is important that in any given case a correct diagnosis shall be made before promising the complete cure which Dr. Schreiber assures us from his mechanical treatment.

Professors Nathan S. Davis, M.D., of Chicago, Dudley S. Reynolds, M.D., of Louisville, Kentucky, Henry H. Smith, M.D., of Philadelphia, and Dr. W. S. W. Ruschenberger, formerly Medical Director of the United States Navy, had the degree of Fellow of the Medico-Chirurgical College conferred upon them by the Trustees of that institution at the annual commencement, held in Philadelphia April 7.

* "Die Mechanische Behandlung der Lumbago," von Dr. J. Schreiber, Aussee-Meran. *Wiener Klinik*, März, 1887.

NOTES FROM SPECIAL CORRESPONDENTS.

PARIS.

Surgical Clinics at the Hôtel-Dieu.—Professor Reclus, the eminent surgeon and eloquent speaker, has been giving a series of very interesting clinical lessons on the usual subjects, and also on some that are new and original. These are so well worthy of attention that we can only regret not being able to communicate them in full; but we will try to give the substance of a few of them. First, we may report one on

Molluscum Fibrosum of the Ano-Rectal Region.—He said that the group of tumors of this region called syphilitic, or condylomata, seems on the increase, and if one does not consider them hemorrhoids, polypus, or cancer, he is apt to regard all these cases as syphilomata. He had observed four patients lately in whom it was impossible to make this specific diagnosis from the history, and so he proposes to class them apart and call them "Molluscum Fibrosum." Professor Fournier, speaking of ano-rectal syphilomata, said that the tumor is characterized by a rigid thickening of the intestinal walls, and that this hyperplasia may be as much as ten millimetres in thickness. The mucous membrane is hard, uneven, and raised by vertical columns which invade the region of the sphincters, and which are replaced by a hard cylinder on the margin of the anus. This sort of tumor is indolent, dry, and hard, and is variable in form, while the growths are so regular that they have been called the "condyloma bouquet." This description is no doubt correct, and he holds syphilis responsible for these narrow, thick tumors which are combined with inflammation of the rectum; but he does not think that certain other tumors that are seen in this region are of the same nature: the latter are those Dr. Reclus ventured to name as above. They surround the rectal orifice in the form of a series of excrescences of different forms, some of them like the half of a pea stuck on the skin, and others larger, with a pedicle; others, again, are flat; but no ulceration is seen. Above the sphincter ani are two tumors as large as small cherries; their pedicle is large and long, allowing the neoplasm to leave the intestine during defecation. The margin of the anus resembles the Marguerite daisy with its petals spread out, while the centre is represented by the two polypus-looking tumors. These tumors obstruct the anal orifice, but the mucous membrane is normal; it is not ulcerated nor hardened, nor is the orifice narrowed, as the finger readily enters. The obstacle, however, is painful, and provokes an alternation of constipation and benign dysentery. It would seem from experience that these tumors often

follow a history of anal fissure and dysentery, though not of syphilis.

Dr. Reclus related one of the cases in full, and went on to say that the name of condyloma is an expression which is very uncertain, as it has been employed in so many different diseases. For some authors it implies syphilis; for others it simply means a sort of modified hemorrhoids. Therefore he has adopted the name of "molluscum" for these tumors, owing to their analogy to those of the skin, and both clinical facts and the pathological anatomy of these tumors warrant the name. They are in fact a sort of prolongation of the mucous membrane, soft, and either pendent or round, resembling an empty bag or a grape from which one has taken the seed. The prognosis is not serious, as they mostly remain stationary.

As to treatment, ablation is advised, or, if they are small, the elastic ligature,—both after local anæsthesia with cocaine; this to be followed by cauterization of the base after the tumor has been removed or has fallen off. If they are very large and inserted high up, a more radical operation is needed, such as rectotomy and destruction of the tumors with the thermo-cautery, or perhaps it would be sufficient to make forced dilatation of the rectum and burn them out with the heated platinum wire.

Cystic Disease of the Breast.—Under the name of "La Maladie Kystique des Mamelles," Dr. Reclus designates a cyst of the female breast which he has found to be quite a common disease, although until his writings in 1883 it was but little known; even now it has not reached the modern surgical text-books. Of course, cysts of the breast are extremely common; all the benign and malignant tumors may give rise to such sacs, and the pathological tissues may form cavities of which the volume and nature vary; but the above-named disease, although frequent, has not as yet received a special description.

This form of cystic disease presents two well-defined characters. First, the cysts are in large number and occupy the whole gland. In the usual cysts this is not so; on the contrary, they form a single cyst, which develops in the middle of a sarcoma or a carcinoma, and leaves the rest of the breast healthy. The second character of this newly-described disease is that it is bilateral, both breasts being attacked. It is well known that the other neoplastic growths are only quite exceptionally placed in both breasts. The following is one of the cases which he described: it will serve as a type of the others, of which so far some thirty have been observed.

A lady of 35 years consulted the Professor for a tumor which she found in her left breast, near the lower and inner portion. It was about as large as a pigeon's egg, round, and very hard, and it was difficult to isolate from the tissue around it. About this principal swelling a careful examination showed a number of small nodes, and these were found all over the gland, but in greatest number near the centre, which seemed full of them, like small lead-shot. Pressure gave no pain, and only from time to time was there a dull shooting ache in the gland. The ganglia in the axilla were healthy and not swollen. Broca, Verneuil, Terrier, and others have seen these tumors, and usually diagnosticated malignant growths, and have advised operation at once. The sensation of a number of little, hard portions around the central swelling, giving an idea of bird-shot, is peculiar to this disease. Operation has not been followed by a return of the tumors excised. Dissection of the removed gland shows it is full of cysts, some fifteen to thirty. In some cases the tissue around them was still strong and of the normal color and structure. The color of the fluid contents varies from yellow to coffee-color. M. Mallassez has made a careful histological examination of this tumor. Is it a benign disease? So far the clinical facts answer yes. One lady operated on some six years ago remains well, and others at various dates show no signs of a return; but the pathological anatomists seem to look upon it as malignant, and do not hesitate to pronounce it a form of true cancer, so that the prognosis must be reserved. On the other hand, the clinical facts lately caused Dr. Reclus not to interfere in a case of a young woman who has this disease in a slight form in both breasts, as he did not like to extirpate both breasts, which he felt was the only radical cure.

While on the subject of breast-tumors, we would like to direct attention to the fact, as shown in this clinic, that these glandular tumors may very often be extremely hard, even wooden in feeling, and without fluctuation, and yet not be malignant in character. To determine the nature of such swellings, it is always best to introduce the needle of a small hypodermic syringe and draw off a little of the contents. This operation is painless as a rule, and innocent if the needle be made aseptic by heating it first, while it will often surprise the operator to find the supposed tumor to be simply mastitis or some much slighter form of disease than he feared, no matter how hard it may seem at first.

Tuberculous Infection by the Genital Passages.—Dr. Reclus said that ever since tuberculosis has been classed with the contagious diseases which are inoculable and parasitic in character every one has tried to determine the road that the bacilli take in penetrating the tissues. These *portes d'entrée* must be numerous, including all the solutions of continuity, both traumatic and ulcerous, of the skin, all loss of substance, and all the epithelial desquamations of the digestive and pulmonary tracts. These modes of invasion can-

not be denied since the hypodermic injections made by Professor Villemin and the experiments of Chauveau upon the injection of tuberculous matter. Can this figured element, the bacillus of Koch, also penetrate the organism by the genital passages? Cohnheim and Verneuil asked this question in 1883, and Dr. Charles Fernet has read several papers before the medical societies in late years in which he tries to establish the proposition that primitive genital tuberculosis can probably be caused by direct contagion in sexual intercourse. Professor Reclus asks, Is this possible? Ought we to accept this doctrine without question? Primitive genital tuberculosis undoubtedly exists, as Cruveilhier, Velpeau, and Reclus have given statistics to prove it. In some thirty recent cases on which autopsies were made, pulmonary tuberculosis and the genital form existed in twenty cases, but in the other ten the lesions were found *only* in the sexual organs. The question is, Can these last cases have a local origin? Can it be communicated as in syphilis for instance, where the sexual organ which is infected contaminates the sexual organ that it penetrates or is penetrated by?

M. Verchère, in a late thesis, and M. Fernet both bring up observations trying to prove the affirmative, but in fact their cases only show one thing, and that is that caseation of the sexual organs can be primary; but they do not in any way prove that the hypothesis of direct inoculation by the genitals is correct, while M. Reclus brings a number of cases to prove the contrary. One of these observations was that upon an infant whose epididymis was found infiltrated with tubercular formation. Verneuil also relates such a case. Lloyd saw the cheesy tubercles in a child of three, Dufour in one of eighteen months. Giraldès adds that in children from six to twelve genital tuberculosis is not at all rare. Professor Guyon also found it in female children. It cannot be pretended that at these ages coition is practised.

To return to M. Reclus's statistics: two of his phthisical patients never had had sexual connection; five others were married, but their wives had not been inoculated from their husbands' genital caseation. To pass by the clinical facts and follow Cohnheim and Fernet in their hypothesis on this form of infection, one must admit that Koch's bacillus exists in semen, which is not at all proved, although it is stated that it has been found in urine. In any case, this inoculation should take place in the vagina or at the mouth of the uterus, and it is well known that tubercular ulcerations are extremely rare in those situations, for it is mostly the mucous membrane of the uterus itself and the ovaries that are attacked. M. Reclus cannot believe that the poor, ill spermatozoid can travel so far as this, for it is said that the white globule when infiltrated with germs loses its amœboid movements, and it must be the same for the figured element of the sperm: so tubercular metritis, salpingitis, ovaritis, etc., can hardly be caused in this way. In men's inoculation by women the conditions are not even so favorable: the great length of the urethra from the glans to the parts usually infected, and the fact of frequent passage of urine cleaning out any stray bacilli that may have wandered in, oppose this idea. There is only one possible theory, and it applies to all cases and explains the tubercular affections of children as well as those of adults and very old people; also the lesions found in the spleen, liver, brain, eye, articulations, and bones.

We first must admit that the bacilli penetrate by some fissure in the skin or by some loss of substance from ulceration of the respiratory or digestive tract. They may stop at this point and form a colony; but mostly they get into the vessels, and are carried on either by the lymphatics or the blood itself, and they enter no doubt in the state of spores, for the anærobic bacilli cannot live except in globules charged with oxygen. Sometimes they leave the circulation, owing to the rupture of some vessel which pours them into the web of the tissues, or else the leucocytes carry them out with them by diapedesis. They are often sterile, or at least they fall into the middle of vigorous anatomical elements that are able to defend themselves against these attacks; but should the tissue in question have the slightest taint or organic fault, an active proliferation takes place at this point, which becomes the seat of primitive or primary tuberculosis, that may remain local, or, later, invade other parts of the organism.

Chlorate of Potash in Cancer.—We must mention, in closing this account of M. Reclus's clinics, that some very remarkable results are being obtained there in the treatment of cancer by chlorate of potash. The matter is still under investigation, however, and it will most likely be treated upon at length by the professor before long, when we will give further details.

Professor Potain on Treatment of Reflex Disturbances of Gastric Origin.—"The different forms of gastralgia determine quite often a series of troubles that should be well understood in order to treat them rationally. Among the organs that are most often affected are, first of all, the heart and the lungs. It will be readily understood that the distention of the stomach after a copious meal can push up the diaphragm, diminish the capacity of the thoracic cage, and interfere with the functions of the organs which it contains, while at the same time the large quantity of liquids thrown into the circulation during digestion fills up beyond measure the circulatory system, and forces the heart into an excess of work which it cannot attend to. One can also well be-

lieve that these disturbances have a chemical origin. All know that the stomach is a vast manufactory where a number of chemical products are produced. When digestion is normal and regular, these substances which it gives birth to have no disturbing action, as they are absorbed and act exclusively in repairing the losses of the organism; but if the digestion be abnormal it permits the absorption of substances which are not fully elaborated, and which are sometimes toxic: such are the leucomaines. Dilatation of the stomach with paresis of its muscular tissues, which has been so well shown by Professor Bouchard, is also a powerful cause of this defective elaboration of the alimentary products, and this has for effect an irritability of the nervous system which produces the reflex phenomena which your dyspeptics will complain of so often. A third and most important cause is the reflex influence exercised by the mucous membrane of the stomach by contact alone of the aliments. The appearance of phenomena at the very moment of ingestion of food in small quantity, before any fermentation has taken place, is of itself quite sufficient to prove this and demonstrate the reality of the influence. The appearance of the reflex pains should not surprise us, as they are first of all quite normal. The tension of the blood is augmented by the liquids of digestion which are thrown into the circulation, and then these in a reflex way give notice, as it were, to the system to receive an influx. All have noticed the redness of the face that accompanies digestion. This is caused by the dilatation of the peripheric vessels to receive the overplus of liquid in the circulation. Suppose, then, an exaggeration of this normal reflex, and then that it should extend to the brain. Migraine, amblyopia, and vertigo would be among the consequences. If it goes to the lungs, then the respiration is interfered with. These normal reflex actions can be diminished as well as augmented. For instance, they are not seen at all when the mucous membrane is the seat of serious lesions, such as ulcer of the stomach, cancer, etc. In regard to the direction that these reflex pains may take, there must be an individual predisposition, either congenital or acquired. Each us of has certain parts of the body more sensitive than others, a *locus minoris resistentiæ*, and it is this point that first comes under the influence of the reflex. Some of these manifestations can be ranged under those inhibitory acts which have been so much spoken of since they were indicated by Brown-Séquard. Take the case of a man who loses his memory in the middle of a meal, and another who after a good dinner becomes impotent, and so on: inhibition can explain but few of these phenomena, for the larger part of them depend on vaso-motor disorders, and these, again, may affect either the vaso-constrictors or the vaso-dilators: indeed, it is a delicate question, often, to say which, in any given case. But as to treatment of these painful maladies: as they are caused by the stomach, its treatment is first of all to be attended to. If the pathological irritation be produced by the presence of some vitiated secretion or badly-digested aliments, then use emetics, washing of the stomach, or purgatives. The alimentary régime is important: order little and often of very digestible substances, and no large meals at any time; watch out for the dentition, as many dyspeptic accidents have as a cause insufficient mastication; give in certain cases milk only as food, to diminish the excitability of the gastric mucous membrane, and absorbing powders, such as prepared chalk, charcoal, phosphate of lime, etc. As the nervous system is often at fault, bromides are suggested, but they are often badly supported by the stomach. They can, however, be used per rectum, in which case hydrobromate of ammonium is the best. One gramme of this salt in a half-pint of water may be injected twice a day, and it will give great relief. Where there is a tendency to nervous depression, valerian in large doses is to be preferred. When the suffering is very intense, for a few days hypodermic injections of morphine hydrochlorate may be used. Then, as to the organ in which is the seat of reflex pain, there is no reason why local medication, by derivation or refrigeration, should not be tried, combined with repose; also the cramps of the calf of the leg may be treated by friction or massage. Pains resembling those of angina pectoris can be cured often by simply putting the hands in warm water, or by giving saturated chloroform-water internally; but, as a rule, great care must be taken not to give preparations of digitalis (which are so often employed for palpitations that are of gastric origin), for this is almost always useless, and it will not calm the pains; most of you know that real heart-pains do not exist. Digitalis may, however, be used in those serious cases of gastric origin where the cardiac dilatation has attained a high degree and it has lasted for a long time; but even here it must be used with caution, much more so than when it is given in heart-diseases which are primarily endocardiac."

When is the Proper Time to give Medicines?—Professor G. Sée made some practical remarks at his clinic to-day that are quite different in some respects from the teachings of the books, and also from custom; but, as they are the results of his nearly forty years' experience in hospitals, they can be followed with certainty. "When is the exact moment to give drugs so that the system will best accept them? There are a few that may be given any time you like, but these are the exception."

Cod-Liver Oil.—"What causes absorption of this oil? The action of the pancreatic and hepatic secretions. Given fasting, it will

most likely cause vomiting, as the juices are not present; for secretion only commences when there is something in the stomach. Children take it well, and the reason is that in them the sense of taste is imperfect. It must be given, then, so that it will pass quickly on to where it can meet the pancreatic juice: so give it *at meals, just after taking soup;* and it can also, curious to say, be well digested without any 'returns,' if taken the last thing at night on going to bed. Cod-liver oil contains fatty acids, more so than any other oil, and absorption proceeds better with it, as an emulsion is not so much needed as in other oils."

Emetics.—"When the intention is to have only mucus vomited, give these fasting; but in indigestion, etc., exhibit *after* eating, so that there will be something to vomit."

Purgatives.—"Here there must be a division. Carlsbad, Hunyadi János, and such like purgative waters should be given at once on rising, and always in *hot water*, to precipitate the elements; if given cold they are often vomited. Magnesia salts, on the other hand, require time, and should be taken at night. Next we come to purgatives that must *never be given fasting:* these are the drastics, such as jalap, aloes, etc." (Here Dr. Sée tells a funny story of his young days, when patients were few and far between, and he got one to whom he ordered a compound aloes pill, with other things, and ordered it to be taken before each meal, with the result that the unfortunate patient had a vomiting-fit each time, and sent at once for the doctor's bill and requested him not to call any more.) "These, then, should be given 'in the middle of a meal;' don't say *during*, for, like *before* a meal, many people want to know the exact moment, and don't understand if you mean an hour before meals or at meals: so be very precise."

Mineral Waters.—Dr. Sée condemns the usual custom of putting these into the wine which is drunk at table, and he says they spoil both the wine and the digestion. He calls attention to the fact that at Vichy, and all the mineral-water stations, the water is always given fasting and some time before a meal. The object being to increase the secretion of the gastric juice, they must be given before meals,—and not just before, but *at least half an hour before.* Vichy, administered in this way, gives better results than when it is used to turn red wine into a sort of ink.

Bitters, cinchona wines, etc., are what are called tonics, on account of the tannin that exists in them: these and acids should be taken *just at dessert*, when the meal is almost over; certainly never before meals.

Iron.—It will precipitate the gastric juice taken before meals, therefore take it when there is something in the stomach to prevent this. It is not known how it gets into the circulation, because it is not seen to go out. In any case, give it *with meals.*

Pepsine.—In supposing that there is some virtue in pepsine, which has not been proved, it should be given just at the end of a meal to assist the digestion of it.

Antiseptic Powder as given for Intestinal Antisepsis in Typhoid Fevers in Paris.—

℞ Naphthalin.,

PARIS, March 28, 1887.

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA NEUROLOGICAL SOCIETY.

FEBRUARY 28, 1887.

(Continued from page 487.)

DISCUSSION ON MORAL IMBECILITY.

DR. H. C. WOOD: Whether we call these cases examples of moral imbecility or give them some other name, we must recognize that there is a depravity which is the result of heredity or some imperfect development of the nervous system. I recently had under my notice a case which parallels those reported by Dr. Kerlin. A woman belonging to a respectable family went astray at a very early age and became the mistress of a married man, bore eight children, and died a drunkard in the gutter at the age of twenty-eight. Of the eight children, all, with the exception of one, perished in infancy. At the death of the mother, this child, a very young girl, was taken by a friend, who endeavored to train her in a respectable manner. The attempt seemed to be successful until the age of thirteen was reached, when, three months before the appearance of menstruation, she ran away and was found in a house of prostitution. Since then her history has been a constant effort to save her and a constant return to bad sexual habits. It finally became necessary to place her in the House of Refuge. There was no tendency to drink in this instance, so that the love of liquor had no part in the precocious, overpowering sexual desires.

Dr. E. N. BRUSH: I was much interested in the graphic description of these cases. I had the opportunity of seeing one of them at the institution at Elwyn. The history of the young woman brings to mind a case which had gone, as Dr. Kerlin says they may do, a little farther. The girl not only became a public prostitute, but had passed into a condition of marked insanity. The mental disturbance was as

much in the line of moral obliquity as anything else. She was very active in causing mischief among the attendants and other patients at the asylum. At one of the visits of a committee of inspection she trumped up a story that the engineer, the apothecary, and one of the physicians had come to her room at night and violated her person. She got one old gentleman very much interested in her case, but before he got through with his investigation she disgusted him by making a similar charge against him.

Dr. CHARLES K. MILLS: I believe that the term moral imbecility is a good one to apply to a certain line of cases, as it has a distinctive meaning. From my experience outside of institutions I could give at least a score of cases similar to those described by Dr. Kerlin. Some of these cases have been in asylums, some have been in prisons or houses of refuge, and some have been in both. I recall one case, now in the Eastern Penitentiary, which has been in three asylums and in three or four penal institutions. A case recently sent to the Pennsylvania Hospital for the Insane by Dr. Wood and myself presents some of the elements which have been mentioned by Dr. Kerlin,—some of the peculiarities seen in the first case reported by him, although not to the same degree. In addition, she had actual spells of mental excitement, possibly a mild form of mania. In the case of a boy recently seen, as in this case, there was a distinct history of neurotic conditions and of insanity in other members of the family. Almost all cases of this kind show a marked element of heredity.

As I have stated, I am a believer in moral insanity as I understand the term, although I do not consider this term a good one, especially for medico-legal purposes. I have been asked on other occasions to produce the cases. Dr. Kerlin has produced four to-night. I think that the members of this Society could bring forward a large number of other cases. The question is not whether or not these subjects have any intellectual aberration at all, but whether or not the moral aberration vastly predominates. If so, the cases should be classed under moral imbecility or moral insanity, whether or not these terms are the best for technical purposes.

Dr. JAMES HENDRIE LLOYD: I unfortunately heard only a small portion of Dr. Kerlin's paper. I think that in the discussion of this question, especially in its practical bearing upon the cases that come before the courts, medical experts are in danger of confounding depravity with insanity. There is a decided distinction between these two. I have always maintained that the mere metaphysical abstraction of moral insanity was an unphilosophical one. Practically we never find a case of a pure moral lesion. There is always an intellectual defect, and frequently a marked congenital defect of the whole brain-organization. We unfortunately know very little of the physical basis of thought, and, until we do know more about this, it seems to me that it is futile to try to make abstract distinctions between moral insanity and depravity. This tendency was probably inherited from the pseudo-psychologists who combated the idea of Locke in regard to the action of the human understanding. I myself do not believe in true moral insanity. In the last case reported, if there were no evidence of mental defect it seems to me a misnomer to call the boy an imbecile. If the boy was full of depravity, and if he had committed a crime, it would be difficult to acquit him before an intelligent jury. I suppose Dr. Kerlin would not claim that he was without intellectual defect.

Dr. FRANCIS X. DERCUM: I think that Dr. Lloyd is correct as regards the unphilosophical character of the term moral imbecility or moral insanity as used in the *abstract* sense. At the same time I can conceive of cases such as Dr. Kerlin has reported. As man ascended from the savage state, the moral faculties were the last developed. Their highest development is inseparably connected with the more intimate social relations demanded by civilization, and is therefore of comparatively recent origin. Now, I can conceive of a child in whom the reasoning powers and the other faculties were developed to an average degree, just as in the savage, and in whom the moral faculties were undeveloped. I believe that in these cases there is a structural and incurable defect,—a morphological defect.

Dr. HARRIET BROOKE: There is in the Woman's Insane Department of the Philadelphia Hospital a young woman, sixteen years of age. She is intellectually very bright. She works efficiently about the ward, and visitors are surprised to learn that she is insane. She has, however, a most violent temper, she steals, she is untruthful, she is cruel, and, when she is crossed, becomes so violent that she takes anything within her reach and throws it at those around her. At such times she is perfectly irrational. When brought to the hospital by her mother and her sister, the latter volunteered the statement that on the father's side there was no insanity, but that the mother of the girl was the only one of the mother's family that was not insane. The sister had herself been insane twice. This case seems to belong to this group of moral insanity.

Dr. ISAAC N. KERLIN: We will be more grateful to Dr. Lloyd if for the terms moral insanity and moral imbecility he will give us expressions defining any better the conditions which we find in a large percentage of so-called feeble-minded persons in many of the commitments to houses of refuge, and in a larger proportion still of those found in such institutions as the Reformatory at Elmira, New York.

Is not the difference between those who argue for and against moral insanity a disagreement about a name, rather than about the existence of a condition accepted by most Germans and many English writers on psychiatry, and supported by Ray, Spitzka, Bannister, and many others in America?

During the past few years there seems to be a growing advance in sentiment among our profession and in the public mind with reference to this subject. Seven years ago a paper read at Lincoln, Illinois, reporting several cases of moral imbecility under the title "Juvenile Insanity," was so thoroughly misunderstood that a discussion followed showing that the gentlemen present had applied the phenomena of *excitable idiocy* to the suggestions of the paper. The idea of a congenital incapacity to receive and act upon moral impressions in any other than the lowest grades of intellectual idiocy was not comprehended. Two years ago I wrote to the non-medical superintendent of one of our houses of refuge, sketching a few of our moral imbeciles, and asking if there were cases corresponding with these in that institution. The question was studiously avoided by that gentleman until an experience had with a case recently sent to him from our Elwyn institution, whereupon I received an ample reply confirming the impression I had formed. A medical officer of the same refuge, within the last few days, examined critically the inmates of the latter institution, and is of the opinion that not a few are moral imbeciles. Dr. Brockway, of the Elmira Reformatory, states that he discovers among his prisoners only six per cent. in whom the moral sense is normal. He prefers to speak of many of his cases as moral imbeciles. It is true that we are using this term for the want of something better; but it certainly defines to the common understanding a class of individuals in whom there is a lack of self-control, a weak volition, and failure in, if not an absence of, the higher elements of a full cerebral development, for which we know no more suitable appellation than moral imbecility.

Adopting these views, their practical application soon comes, in a sequestration of many whose liberty now is only a vicious license. The tendency at our own institution is towards life-detention of all such cases. We refuse for them the ordinary routine of education, because we believe that in educating moral imbecility after the current notions of education we are training experts who may afterwards figure in the rôle of so-called moral insanity; that by giving such subjects any considerable *school* education we are only arming them for more serious exhibitions of evil. It is a radical, often inherited, condition, just as incurable as inherited forms of idiocy or intellectual imbecility. When we shall arrive at this definite conclusion about cranks, habitual drunkards, and the like, and fully apply it, and when we introduce the indeterminate sentence for crime, such sequestration of the morally and socially unfit will be brought about that our human stock will be improved by keeping out of the national blood some terribly bad strains.

It is a noteworthy fact that in most, if not all, the cases which we have determined to be moral imbeciles, there is a neurotic history in the family antecedents; epilepsy, monomanias, inebriety, crime, are frequently the correlative exhibitions in families from which proceed these children of keen intellectual precocities, but inveterate tendencies to vagrancy, prostitution, and lawlessness.

Dr. JAMES HENDRIE LLOYD: With reference to inventing another name for moral insanity, I would say that I do not believe that the condition exists, and therefore I cannot name it. In the last case described by Dr. Kerlin I believe that there is something more than a moral defect. There is something wrong with the intellect. The term moral insanity I consider a misnomer. Guiteau was said to be the subject of moral insanity. The name that I should apply to him would be criminal. As I did not hear the paper, I do not wish to be considered as criticising it. I refer to the subject in general, especially as it concerns the insane and those who are claimed to be insane.

Dr. CHARLES K. MILLS: Dr. Kerlin in his remarks very clearly brought out the strong points in this question; but I believe that Dr. Lloyd's remarks show that he is astray as to the origin of the facts which some of us have been studying. There may be some who believe in this moral imbecility or moral insanity from the stand-point of the pseudo-psychologist, but I do not know these false theorists. The point that I make is this: that Dr. Kerlin, who for twenty-five years or more has been among idiots and imbeciles, and who has studied them in the concrete,—who has seen scores or hundreds where others have seen units,—has come to his conclusions from a different stand-point. Another point in Dr. Kerlin's remarks was in regard to the question of control. Perhaps the very best legal criteria of responsibility that have ever been given are those formulated by Sir Fitz-James Stephens. Among these, certain have reference to the ability to distinguish between right and wrong, not only in the abstract, but in the particular instance; and a higher criterion, which is gradually coming to be included by others,—namely, that a person who does a homicidal or criminal act has lost the power of controlling his actions. I believe that some of his acts are just as much beyond the control of the moral imbecile as are the acts of the hallucinatory lunatic who cannot resist doing that to which he is bidden by a hidden voice. I believe that any one who studies closely many of these cases will come to the same conclusion.

The next paper, by W. A. WILMARTH, M.D., Assistant Superintendent of the Pennsylvania Institution for Feeble-Minded Children, was on

THE PATHOLOGY OF IDIOCY.

The following is an abstract of the paper:

The literature of idiocy consists of scattered reports of post-mortem examinations in institution reports and incidental notes in treatises on disease of the nervous system. I have drawn the material for this evening's paper largely from our own post-mortem records, illustrating the cases presented by photographs and actual specimens of lesions and malformations described, and introducing such facts as I have been able to glean from the above-mentioned sources.

Among the causes which may produce mental defect may be mentioned destruction or non-development of a considerable portion of the cerebral cortex; absence or destruction of important commissural tracts; destruction of the organs of special sense or of their ingoing tracts, preventing the reception of impressions from without; disease of the cerebral vessels, with consequent interference with the nutrition of the ganglionic cells, so necessary for their proper functional activity; atrophy and hypertrophy of the brain, and pressure from cerebral effusion.

ANALYSIS OF FORTY CASES.

Anomalies of the Skull.—Hypertrophy of the skull was seen in five instances, while the bone was unusually thin in three cases. Deformity of the base, especially about those portions of the ethmoid and sphenoid bones which go to make the base of the skull, exists in nearly all congenital cases. This is regarded by Ireland more as a proof of misdirected formative power than as bearing any distinct relation to the mental hebetude.

Adhesion of the membranes, with or without apparent thickening, and varying in extent from a very small localized area to a complete adhesion, exists in forty per cent. of our cases. The post-mortem records at Longenhagen, Hanover (thirteen cases), describe this lesion as existing in 84.6 per cent. of cases.

The average weight of the forty brains was thirty-seven ounces; of the cerebrum, thirty-one ounces; of the cerebellum, 4.40 ounces; of the pons and medulla, a little less than one ounce. The weight of the cerebellum bears a relatively high proportion to the weight of the cerebrum, but bears no relation to the mental state of the individual. Whenever early and extensive paralysis had existed, the cerebellum was generally small.

The frontal lobes very generally appear small, especially in cases of the congenitally feeble-minded. This is evidenced by the short proportionate length of thin lobes measured along its superior border, and by the frequent exposure of the insula by the imperfect development of its lower convolution.

Defect of the commissural system is common. In the corpus callosum it was found in three instances; in the middle commissure in four cases. The posterior and optic commissures were absent in one case.

Irregular arrangement of the fissures and convolutions, consisting of a decided departure from their usual plan, is occasionally seen; confluence of the principal fissures, and more frequently still of the secondary fissures, is common. In about ten per cent. of our forty cases a strong tendency of the fissures to assume a vertical position is shown; the Sylvian or superior temporal convolution may be prolonged to the superior border of the hemisphere, or long, deep fissures may be found in unusual places, where all the fissures whose natural direction is vertical become strongly marked. All these appearances are most marked in children of a low grade of intelligence, and may probably be regarded as an evidence of misdirected formative growth. In two cases of "Mongolian" type of imbeciles the cerebrum in each case was found well developed in its relative proportion, the cerebellum smaller than usual, while the pons and medulla reached only about half the usual weight. No microscopic examination has as yet been made.

General atrophy was found in one case, and internal hydrocephalus with flattening of the convolutions from internal pressure in one instance.

Among the *microscopic appearances* found in idiocy were relative sparseness of ganglionic cells, disproportionate thickness of the outer barren layer, and the presence of nuclear bodies surrounded by a little granular protoplasm, and contained in clear, round spaces in the neuroglia, described by Spitzka. Degenerated and abortive ganglionic nerve-cells, increased density of the neuroglia with abundance of small round cells, thickening of the walls of the blood-vessels, which are sometimes dilated in places, again contracted or occluded. Sclerosis of all degrees of progress. Atrophy of nerve-fibres of the white substance. In at least three cases such destruction of the ganglionic cells in portions of the cortical substance, with condensation of the connective tissue, and in one instance deposit of crystals from absorption of effused blood, that it seems doubtful if any functional activity remained in the affected parts.

Specimens were shown illustrating atrophy of convolution from pressure of bony plates in the dura mater, with malformation of occipital lobes; destructive lesion of frontal lobes, with non-development of the insula and other portions of the hemispheres; also a microcephalic brain, with arrested development of convolutions and general atrophy; another, a fairly well formed brain from an idiot of the lowest grade, where apparent non-development of the cortical substance of portions of both hemispheres existed.

DISCUSSION.

Dr. FRANCIS X. DERCUM: This is certainly a remarkable and interesting paper. I notice that in one of the specimens sent around there is a convolution which I have not seen in any of the brains which I have examined, and this is the inferior internal *pli de passage*. This brings to mind a speculation of my own. It occurred to me, Why should we have a convolution such as the internal *pli de passage?* It is found in monkeys of low grade. Why should we find this convolution recurring in the human brain? It seemed to me that if there be some inherent defect in the power of development of the cerebral vesicles, that defect must make itself most manifest along certain lines. Thus there will be a tendency to absence of certain portions. This defect would be made more evident if the cranium ossified too soon. In such case we should expect the appearance of transverse and perpendicular fissures corresponding to what is found in the brains of monkeys. The question then arises, Why is it that we have ape-like convolutions present? It seems to me that if any one part be suppressed, the brain being a balanced whole, some other part must be developed, and, therefore, ape-like convolutions are necessitated by ape-like fissures.

Dr. CHARLES K. MILLS: The work at the Pennsylvania Institution for Feeble-Minded Children is of great value, not only for what it is, but for what it will lead to and suggest. I have always said that as much can be done towards settling the problems of localization in an asylum for idiots as by experiments on animals or by any form of experimental work, although I do not by any means disregard the value of such experiments. The facts brought out in a general way by this paper show the possibility of our eventually getting at a wider and fuller differentiation of the faculties or so-called faculties of the brain beyond mere motor and sensory localization. As Dr. Wilmarth referred to Dr. Benedikt, it may be interesting to state that about eight months ago I received a letter from Dr. Benedikt, in which he says that he does not advocate the idea that there is an absolutely fixed type of criminal brain, but his observations tend to show that peculiarities of fissures and convolutions occur in low-type brains, and special peculiarities in certain cases.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

A STATED meeting of the College of Physicians was held March 2, 1887, the President, S. WEIR MITCHELL, M.D., in the chair.

DISCUSSION ON DR. RANDOLPH'S PAPER (page 502).

Dr. S. WEIR MITCHELL: The remark that with fatigue comes an increasing tendency to convulsive or useless acts of facial or other muscles is interesting. It seems to show that with feebleness comes increasing waste by overflow of motor energy on to distant ganglia. Perhaps in all states of weakness there is more or less of this tendency. Admitting the accuracy of Dr. Randolph's facts, their explanation is difficult. It may be that the overflow of energy on to symmetrically related centres, or on to others, is competent to weaken them without being strong enough to cause motion; and whether this occurs as regards the opposite hemisphere, or only as regards opposite spinal centres, is hard to say.

(As an illustration, we may by a key close the current of two batteries, A and B, each competent to set in motion a mechanism. Resistances on the one circuit, A, so interfere as to lessen the flow of energy below what will move the mechanism. Meanwhile, the other battery, B, runs to exhaustion. At last we call on battery A for a repetition of the full work done by B, and find A unable to effect the same work as that done by B, on account of having been partially disabled by its previous ineffective waste of energy.

We are free to speculate as to the relative failure of one hand, the last in use, as due to there being but one centre originative of will-signals to the lower ganglia, and itself capable of fatigue. If, however, we entertain any such view, it might be in a measure tested by exacting work from a non-symmetrical pair of limbs, as a foot and hand.

I incline towards the use of the overflow theory to explain the lowered capacity for work by one hand after exhaustion of the other. It would explain why in consentaneous use of two symmetrical parts more work is done than when they follow one the other. The overflow would be in this case valuable, and not damaging or wasteful. This leads me to relate an experiment which Dr. M. Lewis and myself left out of our paper on knee-jerk, but of which I am now sure enough to speak. When we use the maximum power of one hand on a dynamometer, the coinstantaneous use of the other hand adds nothing to the result; and this form of experiment has been commonly used as a test of the reinforcing capacity of the opposite member. If, however, using two fingers or the grip of the thigh adductors on the bulb of a mercurial dynamometer until great exhaustion occurs, and we then make a new effort at the moment of violent use of another member, the mercury leaps quite to the level attained during the first effort by unfatigued muscles. It does not seem easy to explain this fact except by assuming that the overflow of energy usually wasted is in this case made efficient.

The question of muscular, and indeed of ganglionic, tone is brought forward in an interesting way by this experiment. When we strike the patellar tendon, a sudden, distant,

voluntary act adds reinforcement. What is it that happens to the muscle or ganglion so influenced? Is it made more sensitive to impressions, or with this is there a slight flow upon it of motor energy? And if so, can we measure the effect, and thus influence what we conceive of as muscular tone?

For some time I have been engaged in discovering if these reinforcements do cause motion,—*i.e.*, a slight preparatory muscular contraction, making the subsequent volition or other excitatory activity more potent in its results.

I have been able so far to prove that in some spastic cases distant muscular effort, such as a grimace, really causes distinct and measurable movement in the extensors of the thigh, and presumably elsewhere. This interesting discovery has been confirmed in New York and at Harvard. Whether in *normal* man remote motion is thus capable of causing slight shortening of all other muscles does not as yet seem clear. In my own experiments I obtained what seemed to be the same but slighter results than such as were seen in spastic paralysis, and hope very soon to solve doubts and to be able to state my conclusions in more decisive shape. Upon what these may be will depend much of our hope as to realizing clearly the true nature of muscular tone.

We often speak of nerve-power as if there were a common stock from which are drawn the supplies needed by every active organ, and reason that it is unwise to try to carry on at once two functions which exact large expenditures, as digestion and intense thought, or digestion and exercise. Practically, the difficulty may be one chiefly of blood-supply. This is illustrated in the not rare fact that some feeble people cannot digest except when at rest. These facts suggest the idea that perhaps Dr. Randolph's cases would lose ten per cent. of mechanical capacity after a period of exhausting mental labor or during digestion.

Dr. H. C. Wood: The old theory which was used to explain the principle of counter-irritation was that there is a certain amount of nerve-force in the system, and that when, by means of counter-irritation, the nerve-force is drawn to a distant point, it is removed from the inflamed part. Modern science does not recognize the truth of this theory, but it looks to me as though there is a certain amount of truth in it. Every one who has worked in a gymnasium will recall the fact that he cannot use the two hands simultaneously with the same force as he can when the two hands are used separately. A man who can put up a fifty-pound dumb-bell with the right hand and a fifty-pound dumb-bell with the left hand cannot at one time put up a fifty-pound dumb-bell with each hand. This shows some relation between the nerve-centres which we have not as yet gotten at. Dr. Randolph's contribution is an important one looking towards a final solution of this question, but I think that it has not gone far enough to enable us to form any theories with sufficient grounds on which they may rest to hope that the theories are correct.

I believe that when we use our muscles vigorously two kinds of fatigue are produced. There is a local fatigue and a general fatigue. If a man uses the right arm vigorously, he fatigues not only the right arm, but also the whole body. I believe that if these investigations are continued it will be found that after prolonged use of the leg there will be loss of power in the arm, perhaps as great as after previous use of the other arm.

Of course there is a temptation to speculate upon these facts, but the matter must be carried further before speculation will amount to anything. As suggested by Dr. Mitchell, the relation between muscular exertion and mental exercise should be studied. Every one knows by personal experience that when mentally fatigued he is incapable of performing the usual amount of physical labor. This is probably independent of any question of overflow, and goes back to the higher cerebral centres and their relation.

Dr. Charles K. Mills: It seemed to me, while listening to the reading of this paper, that certain well-known clinical facts in cases of brain-disease have some relation to the subject under consideration. For instance, an old hemiplegic, if examined carefully, will be found to have not only the decided loss of power and accompanying conditions resulting from the lesion on the opposite side of the brain, but also a certain diminution of strength in the limbs of the other side, a condition which is not entirely due to the general loss of physical power present. The phenomena which are exhibited by certain spastic cases, or certain cases of unilateral spasm, also seem to me to have some relation to this subject. I have carefully studied the histories of certain cases of spasmodic infantile hemiplegia. In some of these cases the autopsy has subsequently shown the existence of an irritative, destructive lesion in one hemisphere of the brain. If these cases are carefully studied, it will be found that in not a few the spasm has first appeared in one limb, or in a portion of one limb, or in the muscles of one side of the body. After the lapse of months or years, the spasms increase and involve the whole of the original side, and after a time the other side.

We have other illustrations of the same idea in cases of dural spasm, of which there is at the present time an instance in Blockley Hospital, where the spasm was shown by operation to be due to irritation of the dura mater. In this case, and in another on which trephining was performed, the spasms were at different times unilateral and bilateral. Any number of illustrations of this kind could be

adduced from clinical experience. They show that a lesion strictly local, involving only one hemisphere and only a limited portion of that hemisphere, will give rise to local spasms, and after a time to general spasms, the other hemisphere never becoming involved in any direct pathological process. Radiation of irritation from lower centres may, however, explain some of these cases.

Dr. H. HARTSHORNE: I have given some thought to this interesting subject, looking at it from rather a different point of view from that presented so far to-night. The experiments of Dr. Randolph seem to confirm the conclusions of Drs. Mitchell and Lewis quite distinctly, but there is, I think, a great deal more than that in them. They show that there is not that differentiation of centres which has been asserted,—that there is not an insulation, as we may say, of the centres. I should say there is co-ordination and unity more than mere sympathy, especially of those of the two sides of the brain and of the spinal cord. With regard to the brain, we are all aware that our consciousness attests this unity, which is perceptional and volitional. Some simple evidence on this point is familiar to us. How is it that, with the eyes shut, we can place any finger of one hand against the corresponding finger of the other hand? This must be done solely under central guidance. With reference to Dr. Wood's illustration, it seems to me that the inability to lift two heavy weights at the same time is due not to the greater difficulty in the use of the muscles, but to the physical inconvenience owing to the structure of the body. It is awkward. The experiments of Dr. Randolph certainly point the other way. There is another curious experiment which I have frequently repeated. If you write on a blackboard with both hands at once, I believe that you can write your name more readily and certainly backward with the left hand than when the left hand is used by itself. You do not need to pay more attention to one hand than to the other. Here is an example of bilateral unity of volition.

The first result of Dr. Randolph I should explain very much as is done by Dr. Wood: that is, that there is a certain amount only of available dynamic energy at any one time and place, and if that is drawn upon the general sum of dynamic energy, and especially the energy in that particular part, is diminished. When one hand has done all that it can do, the sum of the energy is lessened, and if there is a repetition of the work by the other hand, the amount is less than it would have been if there had been this consumption of power.

The second result is even more interesting, and I think involves psychical factors as well as those which are purely physiological. It does not seem to me that intracranial processes include all in explaining these results. The energy belonging to the spinal centres has to do with forming the sum total of available energy at the time. In explaining the fact that the two hands working together perform more work without exhaustion than when they are used one after the other, there seem to be two other factors, attention and voluntary inhibition. We all know that fatigue is caused by attention. Dr. Randolph spoke of eye-strain; that is also brain-strain. It is said that those who, in working the submarine cable, translate the messages by watching the flash only of light from a mirror, are able to work one hour at a time. The physical effect of attention is shown by a curious experience which has been published in the journals: that is, that if a light be placed near enough to the eye to affect the pupil, yet allowing the subject to see beyond, it was repeatedly observed that if the attention was directed to the light the contraction of the pupil was decidedly greater than when the attention was directed to something beyond. There are also some curious results reported not long ago by Raggi. In experimenting with faint sounds, such as the ticking of a watch in a room where all was silent, he found that there were intervals when no sound was heard. These periods were as long as from seven to twenty-two seconds. The period during which there was audition was from seven to fifteen seconds.

Taking the view which I have already expressed in regard to the unity or co-ordination of the cerebral and spinal centres of the whole cerebro-spinal axis, it may be that the natural and spontaneous method of volition is for the impulse to descend and distribute itself symmetrically to the two sides, and that attention is necessary to prevent this and to make its direction oblique and concentrate it upon one side, and as a result of this effort of attention fatigue is induced.

I am not a believer in the normal functional inhibition of nerves, although this view is held by most authorities. It is apparent that we have three kinds of inhibition: one of the lower centres by the higher, the spinal axis by the brain; another form is pathological, of which there are many instances; and the third form is voluntary inhibition. I need say nothing more in the way of illustration than to refer to the great fatigue or strain which is induced by the effort to restrain strong emotions. There are some circumstances under which it is the hardest thing possible to keep still. That is what I mean by voluntary inhibition. If it be true, as I have conjectured, that there is this normal symmetrical mode of volitional action from the brain downward through the spinal cord to the two sides rather than to one side, there is need to restrain the one not allowed to act. This effort to restrain one side is a draft upon the cerebro-spinal energy, and this involves some fatigue, and thus there is less power if

one act follows the other than if both acts are performed at the same time.

It seems to me that the greatest importance of such observations consists in their effect in modifying the idea which was formerly held as to the meaning of the term "nerve-centre." Long ago Flourens suggested that there is an equivalence of function for all parts of the brain. This view, of course, cannot be held. Later, Brown-Séquard formulated the idea that one hemisphere might do all that the whole brain could do, not in power and endurance, but in function. There has been published within a year a work by Luciani and Seppili on cerebral localization, in which they very clearly point out that a centre is not a point or a cell, or a collection of a few cells; but the idea might be illustrated by our use of the terms "centre of business," or "centre of fashionable residences:" while the business may be conducted largely in one locality, still it is not confined to that part. In one of the diagrams of the authors mentioned, the visual centre is shown by a dark place, the central portion of which is the darkest. This view explains many experiments where the destruction of what is called a centre does not prevent the performance of the function belonging to that centre. It seems to me to be an important advance in nerve-physiology to get rid of the idea of the insulation of centres.

Such experiments as those of Dr. Randolph are of great interest in connection with pure physiology, and also in connection with psycho-physiology, which has now almost displaced the old psychology in the schools, and which occupies a large part of the attention of both physiologists and psychologists.

Dr. Francis X. Dercum: The thoughts that suggest themselves to me have in a large part been embodied in what Dr. Wood has said and in the latter part of the remarks of Dr. Hartshorne. I think it extremely probable, and have so expressed myself in a paper read before the American Neurological Society, that the nerve-centres are not centres defined with anatomical and mathematical precision. The centre is simply the point of greatest functional activity. Take, for instance, the centres for motion, and the sensory areas in the cortex; these are nothing more than the points where the various motions and sensations are focussed. These points are to me nothing more than the gateways of ingress and egress to the general cortex. It also seems to me that, the nervous system being a whole, if any one part acts it must necessarily tire the whole. If one part acts, all the other parts must be fatigued; and the evidence is all the time increasing that the interdependence is so great and intimate that this can be held not simply as a mere speculation, but can be regarded as a fact. To such conclusions does the work of Dr. Randolph, and that of Drs. Mitchell and Lewis, incline.

NEW YORK PATHOLOGICAL SOCIETY.

A STATED meeting was held March 23, 1887, the President, T. Mitchell Prudden, M.D., in the chair.

EXTREME CIRRHOSIS OF THE LIVER AND CHRONIC PHTHISIS.

The President presented two sets of specimens, the first being from a woman who had suffered from the symptoms of cirrhosis of the liver and nephritis. She gave a history of alcoholism. The autopsy revealed two distinct sets of lesions. There was marked cirrhosis of the liver, with chronic diffuse nephritis. There was also chronic miliary tuberculosis and tubercular peritonitis. The symptoms from which she had suffered were due to the cirrhosis rather than to the tuberculosis.

MULTIPLE ADENOMATA OF THE KIDNEYS.

The second set of specimens presented by the President illustrated multiple adenomata of the kidneys in a man who died of an injury. He presented the specimens not because adenoma of the kidneys is so exceedingly rare, but also because in this case the tumors were multiple, which was not so very common; they occurred in both kidneys, which again was not very common. They illustrated the two forms in which adenomata occurred,—the alveolar and the papillomata. They were sharply circumscribed, and varied in size, showing the progress of the growth. Some were brown, some white, the difference in color being due to the deposit of pigment in the brown ones.

PNEUMONIA AND PLEURISY OF SEPTIC ORIGIN IN AN INFANT.

Dr. J. Lewis Smith presented the lungs and related the history of the case of a child which died at the eighth month. It had been healthy, and even at death was not much emaciated. About five weeks ago a cellulitis was noticed in front of the ear. After it had continued about a week the physician discovered fluctuation and lanced the abscess, about two drachms of pus escaping. The discharge from the opening nearly ceased in two or three weeks. This abscess seemed to sustain an etiological relation to the disease of which the child died. Two weeks before its death the child became suddenly very feverish and restless; it vomited several times during the first day and night. The temperature on the first day, he was told, was a little more than 104° F. Throughout the disease there was more than the usual amount of cerebral symptoms seen in pneumonia. Dr. Smith saw the case in consultation, and discovered a small amount of dulness at the apex of the right lung. He saw the child again after about a week, when there was complete dulness over the entire left lung, it being the

percussion-note of pleuritic exudation. The respiratory sounds were indistinct and distant, perhaps slightly broncho-vesicular in character. The apex-beat of the heart could not be detected. The pulse was 180, the respirations 70 to 80. The temperature had been constantly high, at one time 105.5°.

At Dr. Smith's second visit the temperature had fallen to 102°. He was inclined to believe that, in addition to a pleuritic exudation, there was also pericarditis. The autopsy showed a nodule of pneumonia at the upper part of the right lung. There was a little fibrinous exudation along the free border of the upper lobe on this side. Cutting into this portion of the lung, they found as many as eight points of necrosed lung. On the left side about two and a half ounces of serofibrinous exudation escaped; the whole of this lung was covered with pleuritic exudation. The lower lobe was almost completely hepatized. The lower superficial portion of the left lung seemed also to be in a condition of commencing necrosis. There was no pericarditis. Dr. Biggs had made a microscopic examination. Dr. Smith thought the pleuritic and pneumonic inflammation were septic in origin, the point of infection being the abscess on the face.

REMOVAL OF THE UTERINE APPENDAGES.

Dr. JONES presented the ovaries and tubes in about eight cases removed for disease and severe symptoms. The histories of several of the cases were read, together with remarks upon the title of the operation.

BULLET-WOUND OF THE LIVER.

Dr. JACKSON presented the liver of a man who attempted suicide with a pistol (calibre thirty-two). The ball entered three-quarters of an inch below the ensiform cartilage, half an inch to the left of the median line. The patient walked across the room to a bed after the injury, and was doing well in the afternoon, when Dr. Sands probed the wound a distance of four and three-quarter inches. The ball was felt beneath the skin, below the right scapula. The question of laparotomy was raised, and was left for the family to decide. They preferred that it should not be performed. The expectoration of a little bloody mucus was the only symptom of note. A small area of hardening of the lung was present in the neighborhood of the bullet. About a month after the injury the patient's mental symptoms returned: he attempted to jump out of the window. He lay comatose the last five days of his life. The autopsy showed that the ball had traversed the left lobe of the liver and passed through the diaphragm and posterior mediastinum. No hollow viscera were penetrated. There was no general peritonitis, and no hemorrhage into the peritoneal cavity. There was some broncho-pneumonia in both lungs. Death seemed to have been due to the acute mania.

Dr. W. H. PORTER had, last winter, made an autopsy in a case in which a bullet passed directly through the right lobe of the liver, just to the right of the gall-bladder; yet there was absolutely no hemorrhage into the peritoneal cavity. The man lived two or three days after the injury, and seemed to have died from septic infection arising from the entrance of air into the retroperitoneal tissue. He remembered another case in which no hemorrhage followed the passage of a bullet through the liver. He also recalled the case of a man who had quite an extensive rupture of the liver without hemorrhage.

DANGER ATTENDING MOVEMENT OF THE BOWELS CONFINED SOME DAYS AFTER LAPAROTOMY.

Dr. DUDLEY reported further on the case of hysterectomy the specimens of which he presented at the last meeting. The patient had no untoward symptoms, and was doing well, until the sixth day, when he caused the bowels to move. The fact that she had been doing so well was one reason why he did not move the bowels sooner. Soon afterwards serious symptoms developed, and the patient came near losing her life. She was now, however, doing well. This was the second or third case which he had seen in which serious symptoms had followed movement of the bowels confined six or seven days after laparotomy: in one death occurred, and the autopsy revealed a ruptured abscess beneath the stomach. He thought it was a serious mistake to allow the bowels to remain confined so long a time after the operation.

REVIEWS AND BOOK NOTICES.

VON ZIEMSSEN'S HAND-BOOK OF GENERAL THERAPEUTICS. In Seven Volumes. Vol. V. General Orthopædics, Gymnastics, and Massage, by PROFESSOR FRIEDRICH BUSCH, M.D., of Berlin (Translation edited by NOBLE SMITH, F.R.C.S. Edin.); Hydro-Therapeutics, by Dr. W. WINTERNITZ (Translated by F. W. ELSNER). Illustrated. Pp. 624. 8vo, cloth.

The tendency of modern practice of medicine to settle down to routine prescribing of formulæ, more or less stereotyped, for the relief of physical disorders is due to the superficial and hasty teaching of our schools. Men graduate in medicine without any knowledge of the therapeutics of gymnastics, without having ever listened to a lecture on massage, and without any acquaintance with hydro-therapeutics other than a dim idea that it is a variety of irregular practice. Noting the importance of the subjects discussed in

the present volume of this classical series of therapeutic hand-books, we have found our interest stimulated by the able and scientific treatment of them by Busch and Winternitz, who are recognized as pioneers in this department. A valuable bibliography is contained in each section of the volume.

A Practical Treatise on Impotence, Sterility, and Allied Disorders of the Male Sexual Organs. By Samuel W. Gross, A.M., M.D., LL.D., etc. Third Edition, thoroughly Revised. With Sixteen Illustrations. Philadelphia, Lea Brothers & Co., 1887. 8vo, cloth. Pp. 172.

This handsomely-printed monograph upon disorders in the treatment of which the author has a well-earned reputation now appears in a third and thoroughly revised edition; it has also been honored by a Russian translation. In its four chapters Impotence, Sterility, Spermatorrhœa, and Prostatorrhœa, and their various forms, are discussed from a clinical stand-point especially, with judicious remarks upon pathology and treatment. The relation existing between strictures of large calibre with masturbation on the one hand and impotence on the other is brought out prominently in the histories of several cases, which without urethral examination would have been classed as psychical impotence.

Medical Electricity. A Practical Treatise on the Applications of Electricity to Medicine and Surgery. By Roberts Bartholow, A.M., M.D., LL.D., etc. Third Edition, Enlarged and Improved, with One Hundred and Ten Illustrations. Philadelphia, Lea Brothers & Co., 1887.

The present edition has been enlarged by the additions chiefly in the sections upon therapeutics, and a fuller account is given of the appliances for electrical illumination and the apparatus used in galvano-cautery. Galvano-faradization and electric baths have also received fuller consideration. No practising physician can afford to use electricity without informing himself as to its scientific applications, and to those wishing a good manual upon the subject this handsomely printed and illustrated treatise will prove very acceptable.

Manual of Treatment. A Concise Presentation of the Modern Methods of Treating Disease Employed by the best Authors, Teachers, and Practitioners, arranged with special reference to the Needs of American Practitioners. By C. F. Taylor, M.D., and William F. Waugh, M.D. Published by the Medical World, Philadelphia, Pennsylvania, 1887. Cloth, 8vo. Pp. 532.

This manual of practical therapeutics is in the popular and convenient form of an encyclopædia, the subjects being alphabetically arranged for convenience of reference. The practical recommendations of many physicians, both European and American, are given in the treatment of the principal diseases, the style being direct and to the point. Great industry has been displayed in collating so many authorities, but greater editorial skill is shown in the careful condensation of the paragraphs on treatment. We think that this book will meet with a large sale, and will more than satisfy those who purchase it.

NEW REMEDIES AND CLINICAL NOTES.

Waking Numbness.—Dr. Andrew H. Smith, in the April number of *The American Journal of the Medical Sciences*, describes under this title a heretofore undescribed neurosis, and reports four cases, from a study of which it appears that the numbness is something added to the normal condition. It is a purely subjective condition. There is no paralysis of motion or sensation; the tactile sense is unimpaired; there is no change in the temperature of the affected part; the surface is not blanched or mottled; there is no tenderness on pressure. These characteristics separate this condition widely from those known under the name of night-palsy, local asphyxia, digiti mortui, Raynaud's disease, erythromelalgia, and from the various paræsthesias and acroneuroses heretofore described.

Doubtless the conditions upon which the numbness depends are present during sleep, but the sensation is not sufficiently strong to arouse the sleeper, and he first becomes conscious of it when awakened by some other cause.

The cause of this condition is probably central, since the effect is usually symmetrical. It would seem to be connected with the lowering of the circulation which takes place during sleep, and to disappear when the circulation returns to the waking condition, whether the return be spontaneous or the result of rubbing, etc. As to the latter, it is doubtful whether it has any other effect than that upon the general circulation which the muscular exertion would necessarily produce.

As for treatment, in the only case in which the condition existed by itself, and independently of more serious conditions, ergot, digitalis, strychnia, and aconite were tried at different times, but without result. The inconvenience produced by the affection was so slight that no treatment was carried out efficiently, so that even these negative results were of no value. In each of the other cases there was a diseased condition present to which the numbness was subordinate, and which afforded the indications for treatment. In proportion as the treatment of the underlying condition was successful, the numbness disap-

peared. If it be true that the cause is central, no local treatment is likely to be of service.

TYPHO-MALARIAL FEVER.—Dr. J. Edward Squire, in a study of typho-malarial fever, which appears in the April number of *The American Journal of the Medical Sciences*, maintains that this disease is not a subdivision of enteric fever, but a form of malarial fever, and defines it as "a malarial fever which has assumed that adynamic type which is present in enteric fever." He gives a concise account of its history, symptoms, pathology, diagnosis, and treatment.

MISCELLANY.

MATERNAL INJURIES REPRODUCED UPON THE FŒTUS.—There was a very curious case of medical evidence offered recently in a court in Mercer County, Pennsylvania, which is thus stated in the *Albany Law Journal:*

"Some weeks ago, a young woman named Scott, who was soon to become a mother, appeared before a justice of the peace and swore out a warrant for the arrest of a young man named William Bloodgood on a charge of assault and battery. The young woman swore that, two weeks previously, the prisoner had come to her house, and as she objected to his remaining he had choked her until she was almost unconscious, and had twisted her left wrist, almost dislocating it. She said the marks of his fingers and thumb were visible on her throat for several days, and her wrist had remained crooked for some time. She had no witnesses of the assault. Bloodgood admitted having been at the young woman's house, but denied the assault. The justice held him, however, for trial.

"The case came on for trial. The complainant appeared, carrying her three-weeks-old baby. She swore to having been assaulted by the prisoner, as she had sworn before the justice of the peace, and that she was the mother of the child in her arms. Her lawyer then offered to show the baby to the jury. After examining it the judge allowed this, and the prosecuting lawyer took the infant to the jury, and, uncovering its throat, revealed to them the distinct marks of four fingers on one side of it, and the plain and unmistakable impression of a thumb on the other. After the remarkable birthmarks had been examined by the jury, the lawyer uncovered the baby's left wrist. It was twisted out of shape and swollen, as if it had been suddenly wrenched. These marks on the throat and the twisted wrist corresponded exactly with the injuries the baby's mother swore, more than a month before it was born, to having received at the hands of the prisoner Bloodgood. After this startling and most extraordinary evidence was presented, the prosecution rested its case. The prisoner was convicted."

The facts of the case were taken from newspaper articles, and not from official reports, so that there may be chance for some inaccuracy; but the case is certainly a most remarkable one.

It will be noticed that the woman was far advanced in pregnancy, when it is usually considered that physical effects upon the fœtus are not probable. There does not seem to have been any expert medical testimony produced to connect scientifically the birthmarks with the alleged assault, and yet it is certain that little baby presented to the minds of the jury the strongest corroborative evidence of fact of the assault.

A LIBELLOUS EPITAPH.—It is generally considered a mean and despicable trait to speak ill of the dead, but the question whether a person could libel a dead person has only been recently passed on. In an English court the following very curious funereal inscription came up for discussion. It was an epitaph proposed for the statue of a deceased person: "In Honour of John Batchelor, a Native of Newport, who early in life left his country for his country's good; who on his return devoted his life and energies to setting Class against Class; a Traitor to the Crown, a Reviler of the Aristocracy, a Hater of the Clergy, a Panderer to the Multitude, who, as First Chairman to the Cardiff School Board, squandered funds to which he did not contribute; who is sincerely mourned by Unpaid Creditors to the Amount of Fifty Thousand Pounds; who at the close of a wasted and misspent life Died a Demagogue and a Pauper, this Monument, to the Eternal Disgrace of Cardiff, is erected by Sympathetic Radicals. 'Owe no man anything.'" An epitaph like this certainly comes very close to the libellous grade; but the court held that there could be no libel strictly against the dead, and, as this epitaph contained nothing reflecting on the living, it was decided that nothing could be done.

A short time since a case came up for trial in Missouri where a father, believing that his son had been drowned by some playmates, placed this statement on the gravestone. He was obliged to pay heavy damages for the exercise of his spite against the living. In the first case given, that of the Cardiff gentleman, there seemed nothing reflecting on the living, so the judge was compelled to dismiss the case.

THE DIRECT ACTION OF ATROPINE, HOMATROPINE, HYOSCINE, HYOSCYAMINE, AND DATURINE ON THE HEART OF THE DOG, TERRAPIN, AND FROG.—Dr. H. G. Beyer, from an experimental study of the action of these drugs, which appears in the April number of

The American Journal of the Medical Sciences, reaches the following conclusions:

1. Atropine, homatropine, hyoscine, hyoscyamine, and daturine are stimulants of the sympathetic nerve apparatus of the heart.

2. The vaso-motor portion of this nerve apparatus is affected by comparatively small doses of these drugs, giving rise to either acceleration or augmentation in the heart's action.

3. The inhibitory portion is excited by large doses only, giving rise to slowing of the heart's action, and, finally, causing diastolic arrest.

4. The muscular substance of the heart is greatly excited by atropine, homatropine, and daturine, and only slightly so by hyoscine and hyoscyamine.

5. The vaso-motor nerves and their ganglia are the first to become exhausted, the inhibitory nerves and their ganglia are the next, and the muscular substance is exhausted last of all.

6. The slowing of the heart's action which follows the administration of these drugs in the intact animal may be sufficiently accounted for by their influence on the inhibitory nerves and ganglia of the heart itself.

7. The acceleration following the administration of certain doses of these drugs cannot be sufficiently accounted for by their action on the accelerator nerves and ganglia within the heart, but is principally due to causes resident outside this organ.

The Association of Genito-Urinary Surgeons will hold its first annual meeting at Lakewood, New Jersey, May 17 and 18. An interesting programme has been issued. Dr. E. L. Keyes, of New York, is Temporary Chairman, and Dr. R. W. Taylor, of New York, Temporary Secretary.

The Penn Mutual Life Insurance Company of Philadelphia has appointed Drs. Clara Marshall and Anna Broomall examiners for a special class of risks among women.

The American Climatological Association will hold its Fourth Annual Meeting in Baltimore on Tuesday and Wednesday, May 31 and June 1.

NOTES AND QUERIES.

OBITUARY.

Professor James Stewart Jewell, M.D., a prominent physician in Chicago, died on the 18th inst., after suffering with a complication of disorders for more than five years. He was born at Galena, Illinois, September 8, 1837, and after pursuing the regular course of medical studies at the Chicago Medical College, he was graduated from that institution in 1860. Four years later he was elected to the vacant chair of Anatomy in the faculty of his Alma Mater, which he filled for five years. In 1872 he was elected Professor of Nervous and Mental Diseases, which connection he retained for many years, and at the time of his death he was Professor Emeritus. He rendered substantial service to the cause of neurology in this country, both by his teaching and writings, and by establishing the *Journal of Nervous and Mental Diseases*, of which for several years he was chief editor. He was also one of the organizers of the American Neurological Association. A few months ago he began a new journal, the *Neurological Review*, but it was soon suspended, owing to his increasing ill health. By those who had the good fortune to know Dr. Jewell he was highly esteemed, and he was respected by all.

OFFICIAL LIST

OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U.S. ARMY FROM APRIL 10, 1887, TO APRIL 23, 1887.

Lieutenant-Colonel J. R. Smith, Surgeon. — Detailed as member of board to meet in Washington, D.C., April 28, to prepare rules and regulations for the government of the Hospital Corps of the Army. Par. 8, S. O. 92, A. G. O., April 21, 1887.

Major Morse K. Taylor, Surgeon.—Relieved from duty at Fort Sill, Indian Territory, May 10, 1887, to proceed home, San Antonio, Texas, preparatory to retirement. Par. 20, S. O. 92, A. G. O., April 21, 1887.

Major Charles L. Heizmann, Surgeon.—Detailed as member of board to meet in Washington, D.C., April 28, to prepare rules and regulations for the government of the Hospital Corps of the Army. Par. 8, S. O. 92, A. G. O., April 21, 1887.

Captain Fred. C. Ainsworth, Assistant-Surgeon.—Detailed as member of board to meet in Washington, D.C., April 28, to prepare rules and regulations for the government of the Hospital Corps of the Army. Par. 8, S. O. 92, A. G. O., April 21, 1887.

Captain Edward B. Moseley, Assistant-Surgeon.—Ordered for duty at Whipple Barracks, Arizona. S. O. 89, A. G. O., April 18, 1887.

Captain John J. Kane, Assistant-Surgeon.—Resigned April 13, 1887. S. O. 85, A. G. O., April 13, 1887.

Captain Chas. Richard, Assistant-Surgeon.—Granted two months' leave of absence, on surgeon's certificate of disability. S. O. 82, A. G. O., April 9, 1887.

First-Lieutenant Freeman V. Walker, Assistant-Surgeon.—Ordered from Fort McIntosh, Texas, to Post of San Antonio, Texas. S. O. 45, Department of Texas, April 11, 1887.

First-Lieutenant Julian M. Cabell, Assistant-Surgeon (recently appointed).—To proceed to Fort Omaha, Nebraska, and report in person to the commanding officer of that post for temporary duty. Par. 19, S. O. 92, A. G. O., April 21, 1887.

Appointments.—To be Assistant-Surgeons, with the rank of First-Lieutenant, to date from April 14, 1887: Charles E. Woodruff, Julian M. Cabell.

The Army Medical Board, New York City, New York, is dissolved. S. O. 82, A. G. O., April 9, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U.S. NAVY FOR THE TWO WEEKS ENDING APRIL 23, 1887.

Passed Assistant-Surgeon S. H. Griffiths.—Detached from the U.S.S. "Lancaster," and waiting orders.

Passed Assistant-Surgeon C. T. Hibbett.—Detached from duty on iron-clads, City Point, Virginia, and waiting orders.

Passed Assistant-Surgeon E. H. Marsteller.—Ordered to duty on iron-clads, City Point, Virginia, the 20th inst.

Passed Assistant-Surgeon A. C. H. Russell.—Ordered to duty at Naval Laboratory, New York, May 2, 1887.

Passed Assistant-Surgeon A. C. Heffinger.—Ordered to Widow's Island, Maine, to superintend building a naval hospital, wharf, and other improvements, under instructions of the Surgeon-General of the Navy.

Assistant-Surgeon Charles E. Woodruff.—Resignation accepted, to take effect April 8, 1887.

PHILADELPHIA, MAY 14, 1887.

ORIGINAL LECTURES.

ON THE TREATMENT OF SCARLET FEVER.

BY FRANK E. WAXHAM, M.D.,

Professor of Diseases of Children in the College of Physicians and Surgeons, Chicago, Illinois.

Reported by WILLIAM WHITFORD.

GENTLEMEN,—We will consider today the therapeutics of scarlet fever, and, as indicated in our last lecture, the treatment of the disease will be preventive, hygienic, and medicinal.

Preventive Treatment.—In the prevention of the contagious diseases there is a wide field for investigation. We have no specific preventive of scarlet fever as we have of smallpox. The virus of the disease has been inoculated into animals, but its severity has not been modified, the subjects almost invariably dying within a few days from the violence of the malady. It is barely possible that future investigations will prove that the virus, by repeated cultivations, may be so modified that it may be safely inoculated into the human subject, but as yet our preventive measures are limited to isolation, ventilation, disinfection, and the application of antiseptics to the body of the patient.

Perhaps I should refer, in this connection, to certain remedies that have been brought forward from time to time as useful in the prevention of this disease. Belladonna is perhaps the most favorably known in this respect. It has been approved frequently by authorities, and recommended as a remedy which when given previous to an attack of the disease will prevent its occurrence. Boric acid has been more recently advocated for the same purpose, but it is extremely doubtful whether we have any remedy which, administered internally, will prevent an attack of scarlet fever.

Isolation perhaps is our most important preventive measure. Too frequently, indeed, we see cases treated in luxurious apartments, where there are richly upholstered furniture, Brussels carpet, and heavy lace curtains, all of which retain the poison of the disease for weeks or even months. Too often the physician enters the house of a patient sick with scarlet fever, and, removing his overcoat and leaving it upon the rack, goes to the sick-room, and perhaps examines his patient carefully for half an hour, collecting all the poison possible upon his person. Then, after leaving the apartment, he puts his overcoat on again, thus carrying with him the germs of the disease to be distributed to the next family that he visits. This is all wrong. The conscientious physician will take every precaution possible towards the prevention of this dreaded disease of childhood. The moment we are suspicious of an attack of scarlet fever and are called to see a patient, and find the rapid pulse characteristic of the disease, together with occasional vomiting and sore throat,—when we observe these symptoms we should at once isolate the patient, and then if we have made a mistake no harm certainly will have resulted, but if the case proves to be one of scarlet fever other lives may be saved by this precaution. There are two methods of isolation,—viz., (1) we may place the patient in a spare room alone, with an attendant or nurse; (2) we may send the well children away from home, to the friends, neighbors, or relatives of the family. But here we often meet with the remark that they have no friends, no neighbors or relatives to whom they can send their well children. In Chicago I know there is no place where well children can be sent: there is no public institution or hospital where well children, under such circumstances, can be taken and cared for until the danger has passed and until they can return safely to their homes. In every large city there should be a hospital or refuge where such children can be carefully watched and cared for until they can be safely taken home. If possible, we should take the patient to a large room and there isolate it with a nurse; the meals should be taken to it; and the nurse, whenever she leaves the room, especially to mingle with the other members of the family, should thoroughly disinfect her hands and face and change her clothing. The child should remain in the apartment not only until the disease has subsided, but until desquamation has completely taken place. The discharges from the nostrils and mouth should be collected on old cloths and should be burnt; the discharges from the bowels

should be passed in some antiseptic fluid and destroyed. (For instance, we may use a solution of eight ounces of sulphate of zinc, one ounce of carbolic acid, and three gallons of water; or, in preference to this solution, we may make one of one pound of chloride of iron, an ounce of carbolic acid, and three gallons of water. This makes an excellent antiseptic solution.) The bedding, sheets, and clothing of the child worn during the sickness should not be removed from the room until they are thoroughly saturated with the first antiseptic solution mentioned: they may then be removed and boiled in water, which will effectually kill the poison. After complete desquamation has occurred and the skin has returned to its natural suppleness and softness, the child should be anointed with some carbolized ointment and fresh, clean clothes placed upon him, and then allowed to mingle with other members of the family. After the patient has left the room a pound or three pounds of sulphur should be saturated with alcohol and burned, and the fumes should remain several hours in the apartment, then the windows should be opened and the room thoroughly ventilated. If in addition to these measures the room be repapered or recalcimined, then there will be little danger of its being a medium of contagion. I should have remarked also that all superfluous furniture should be removed from the room, the curtains taken down, carpets taken up and removed, leaving nothing behind that cannot be thoroughly disinfected. The wood-work around the room should be scrubbed after the recovery of the patient. In case this is impossible, and the crowded condition of the people will not permit of complete isolation in the home, you can place the patient in a corner of the room on a bed, keep the well children away from him as well as you can, apply frequently antiseptic ointments or lotions to the body of the patient, and in this manner you will be able to destroy the poison and prevent its escape about the room. For this purpose we might use a combination of cold cream and glycerin, to which a little carbolic acid may be added, or cosmoline or fresh lard into which the carbolic acid is incorporated. This should be applied all over the body of the patient every two or three hours. I well remember being called to a family consisting of father, mother, and three children, and one of the children showed unmistakable evidences of an attack of scarlet fever. All the initial symptoms were present: rapid pulse, chill, slight vomiting, etc. I endeavored to impress upon the minds of the parents the importance and practicability of sending the well children away from home, but they informed me it was impossible to do so. They lived in three small apartments: one was used for a bedroom (in which there were two beds), the other two for sitting-room and kitchen. The bed which the well children occupied was taken from the bedroom and placed in the sitting-room; the door was open so as to warm the sick-room comfortably. The well children were prevented from entering the room of the patient, antiseptics were applied repeatedly for two or three weeks (and he, by the way, had a severe, sharp attack of the disease), and when the child left the room it was thoroughly disinfected, and the other children escaped the disease. I think it was due entirely to the local application of antiseptics as previously directed.

Hygienic Treatment.—The hygienic treatment of the disease requires keeping up a uniform temperature day after day, night after night, and week after week, until convalescence has occurred. This is of great importance. The temperature range of the apartment should be from 68° to 70°; but in the latter stages of the disease, after the fever has subsided, it may be higher, and we perhaps may have a temperature of 70° or 75° during convalescence, because complications are more liable to occur during this period. There is a greater liability to complications attending a low temperature. The diet should be simple, plain, and nourishing. The room should be well ventilated. It is a mistake to heap clothing upon the child, and thereby increase its discomfort; the clothing should be just comfortable. If the child is hot and feverish, simply throw a sheet or thin coverlet over it, and do not attempt to increase the body-temperature by a great amount of clothing. Frequently you will find ignorant people who, having a child coming down with measles or scarlet fever, will put hot poultices upon it, then over all these three or four heavy blankets, and the consequence is that the child will be nearly suffocated. The idea on the part of the parents is to keep the child warm, so that the rash will come out

well. This is dangerous: it will increase the bodily temperature and irritation; it will do no good whatever. The clothing, therefore, should be light and comfortable. So much for the hygienic treatment.

Medicinal Treatment.—In regard to the medicinal treatment let me say this: it is impossible to abort an attack of scarlet fever. If the child has been exposed and is susceptible to the disease and manifests unmistakably the initial symptoms, it must pass through the attack. It is impossible by heroic measures or otherwise to break it up, so that if the attack be mild we will be satisfied simply with rigid preventive and hygienic treatment, together with careful watching of the patient, without the administration of much medicine. Give the child plenty of water to drink; I have never known any harm to result from an abundance of water. Any child suffering with a contagious disease should have plenty of cold water. If the skin is hot it should be thoroughly anointed with lard or vaseline, cold cream or cosmoline, as previously mentioned. The application of these will serve a double purpose: they will prevent the diffusion of the contagion through the room, allay the burning and irritability of the skin, and are at the same time soothing to the inflamed epidermis. The frequent application of soothing lotions, the occasional cool sponge-bath, may be all that is required in mild cases. If, however, the attack is somewhat more severe; if the pulse is rapid, the temperature elevated to 103° or 104°, then perhaps we should resort to some medication, such as a combination of quinine. I believe that quinine is one of our most useful remedies in the treatment of diseases of early life. We might give the following:

℞ Quininæ sulph., ℈j;
Ext. glycyrrhizæ fld. (Burrough Bros.), f℥ss;
Ol. anisi, gtt. vj;
Syr. simp., ad f℥ij. M.

Sig.—Teaspoonful of this may be given every three hours. It is an antipyretic.

In addition, for a child two years old, we may give:

℞ Tr. digitalis, gtt. xxxij;
Liq. ammon. acetatis, f℥ss;
Syr. simp., f℥ss;
Aquæ, q. s. ad f℥ij. M.

Sig.—Teaspoonful to be given every three hours, alternating with the quinine.

If the case is not dangerous and severe, this will be sufficient. Let us suppose there is a throat-complication,—the inflammation of the throat severe and false membrane forming in the pharynx. Instead of the digitalis mixture we might use the following combination:

℞ Tr. ferri chl., gtt. xxxij;
Glycerini, f℥ss;
Potassii chloratis, gr. xx;
Syr. simp., q. s. ad f℥ij. M.

Sig. Teaspoonful to be given alternating with the quinine-mixture.

I believe no good can result in these cases from a continual swabbing of the throat with a rough sponge and the use of astringents. The physician can occasionally with benefit paint the pharynx with some astringent lotion; but a coarse swab in the hands of an attendant will only increase the irritation of the pharyngeal mucous membrane and aggravate the symptoms. In place of the swab, we will accomplish far better results with the hand-atomizer, which is less annoying to the child. We may make this combination:

℞ Acidi carbolici, gr. ij;
Potass. chloratis, gr. xx;
Glycerini, f℥ss;
Aquæ, ad f℥ij. M.

This may be used in the atomizer every hour or so. The throat and pharynx should be thoroughly sprayed by such a solution, and it will not only be soothing to the pharyngeal mucous membrane, but antiseptic as well. We might gain a point by the use of lime-water in the solution, instead of plain water, inasmuch as it is a solvent to false membranes. If there is invasion of the nasal passages and a mucopurulent discharge from the nostrils, we should resort to the use of the spray. Let us attack the mucous membrane of the nostrils the very moment it becomes invaded, or the very moment symptoms of coryza manifest themselves. Immediately make use of the atomizer or nasal douche,—a solution of the bichloride of mercury or carbolic acid, to act upon the naso-pharyngeal mucous membrane,—and in this manner we will in many cases prevent the inflammation from extending into the middle ear by way of the Eustachian tube. We will prevent in many of these cases the suppurative inflammation that so frequently results in perforation of the membrane of the drum of the ear, with obstinate and offensive discharges.

If the disease be accompanied with high

temperature, we must endeavor to reduce it by the frequent use of the cool sponge-bath, the cold bath, or the cold pack, or by the use of antipyrin or thallin. I believe these measures are far better than large doses of quinine, for the large doses necessary to reduce the temperature in a child will usually disturb the stomach and interfere with digestion; they will be frequently rejected, and consequently no benefit will be derived from them. We will resort then to frequent sponging of the patient's body with water in which some alcohol is placed. If this does not reduce the temperature, we may give ten or twelve grains of antipyrin per rectum, the injection to be repeated in an hour or so: in fact, we give two or three injections until the temperature is reduced. If the antipyrin fails, you can make use of thallin; but antipyrin is preferable to thallin, for the reason that it is not so depressing in its action. If these measures fail, we will resort to the cold bath. In giving the cold bath let us give it in such a manner as to produce no shock to the system. Let it be tepid, and reduce the temperature of the bath by adding pieces of ice; this will gradually lower its temperature without producing shock to the patient. Or in place of the cold bath we may use the cold pack. If we use the cold pack, the sheet which is wrapped around the child should be first wrung out of tepid water; after it is wrapped around the child it should be saturated by sprinkling cold water upon it, and then a blanket should be placed over the sheet so as to keep the child comfortable, and in this manner you may reduce the temperature gradually, and the patient may be able to remain in the pack ten, fifteen, twenty, or thirty minutes. After this time everything should be removed, the child thoroughly dried and placed in bed. In a great majority of cases the temperature will fall two or three degrees. Some authorities recommend that the patient be stripped and placed in a wash-tub, and then several pails of cold water thrown upon it at some little height; but I would not advise this process. If you were to take a little, frail, delicate child dangerously ill with scarlet fever, place him in a tub and dash cold water upon him, I should fear the result: the shock to the system would be too great.

In those cases attended with grave cerebral symptoms such as convulsions, followed by stupor and coma, we should make use of the bromides, or if the bromides fail to control the convulsions we might add chloral. In addition to this the head should always be kept cold, and for this purpose we may use the bladder or the rubber ice-bag, filling it half full with pounded ice and bran, which should be kept about the head. The rubber coil filled with ice-water, placed over the head, is also beneficial in these cases.

Complications.—A few words in regard to the treatment of the complications. If there is enlargement of the lymphatic glands of the neck, with tenderness, we should apply over them a pad saturated with cold water, or take a small rubber bag and fill it partly with pounded ice, and place it over the inflamed, swollen glands. The idea is to prevent suppuration if possible. If you detect fluctuation, it should be poulticed and opened early, and then dressed antiseptically.

In regard to the otitis of the middle ear which is so troublesome, and frequently so dangerous, at the very onset of the symptoms we should apply a leech either back of or in front of the ear. The hemorrhage should be encouraged, if the child is not too greatly prostrated, by the application of warm poultices, which will generally abort an attack of inflammation of the middle ear and greatly allay the pain. But if the pain be sharp and excruciating, we may use in addition an opiate mixture, dropping within the ear a few drops of warm water containing one-sixth of a grain of morphia, or a small quantity of glycerin containing a few drops of the tincture of opium. We should watch the symptoms of otitis very closely indeed. If the pain continues, especially if there are cerebral symptoms with a bulging of the membrane of the drum of the ear, then paracentesis should always be performed and the accumulated pus allowed to escape. After paracentesis has been performed, antiseptic lotions should be used in the ear. A solution of boric acid is one of the best; say a scruple of boric acid to an ounce of water. A half-teaspoonful of this may be used three or four times a day, or we may use the peroxide of hydrogen, which is a very useful remedy: it penetrates the opening that has been made in the drum of the ear and destroys the pus. It may be used three or four times a day. A great many authorities recommend powdered

boric acid to be placed in the ear-cavity two or three times a day; but you must remember that by the use of boric acid you may occlude the opening of the drum of the ear and prevent an escape of the pus, and then you will have a return of pain in the organ, and perhaps cerebral symptoms as well. If this occur, you must at once resort to the douche in the ear by means of a fountain syringe, using a pint or more of warm water. It will be sedative in its effect; it will remove the incrustation that has formed about the opening, as well as the obstruction.

The rheumatism that occasionally complicates scarlet fever is usually mild, not dangerous, and an anodyne or opiate administered at night, together with cotton padding placed about the joints, will generally be sufficient. If this does not suffice, we may use quinine or salicylic acid, or any of the other rheumatic remedies.

Nephritis I have already referred to as one of the most frequent and one of the most dangerous complications of the disease. I alluded to the necessity of keeping children in the house for three or four weeks in order to prevent the occurrence of this complication, and to the fact that this complication occurs during the period of desquamation, and it is generally the result of exposure to cold and dampness. Hence you can see how important it is that we should give strict and imperative directions with regard to keeping patients within until desquamation is entirely completed and the skin has returned to its suppleness and normal condition.

If dropsy has occurred and the child is very much weakened, then tonics are in order: iron—any of the ferruginous tonics—may be used. These are indicated together with cod-liver oil. If the dropsy is considerable, and there is urgency in regard to the case, you may use cathartics and diaphoretics. Endeavor to eliminate the urea by the skin and from the bowels. In these cases the urine is usually lessened in quantity and loaded with albumen. Let us avoid stimulating the kidneys, for they are already congested, and if we stimulate them to increased activity by powerful diuretics we will naturally do harm. Let us therefore act upon the skin and bowels rather than upon the kidneys. If the case, as I have stated before, is urgent, we may make use of a mild diuretic, such as digitalis containing a little syrup of squill and spirit of Mindererus. We may use the following:

℞ Tr. digitalis, gtt. xxxij;
Liq. ammon. acetatis, f℥ss;
Syr. scillæ, f℥ij;
Aquæ, q. s. ad f℥ij. M.

Sig. A teaspoonful three or four times a day to a child two years old. Digitalis is an excellent cardiac stimulant; it is a tonic as well as a mild diuretic. If the urine is scanty we must use more powerful remedies, such as the hydragogue cathartics. The mineral waters or a solution of the citrate of magnesia will be useful in such cases.

Let us act upon the skin by diaphoretics; and we may use in this connection the sweet spirit of nitre or spirit of Mindererus. Here is a point to which I desire to direct your attention: the sweet spirit of nitre is a powerful diaphoretic; it is a cardiac and cerebral stimulant; it stimulates the secretions of the stomach, salivary glands, and pancreas when administered internally. If you administer it and at the same time keep the surface of the body warm, it will act as a diaphoretic; but if the surface be kept cool, then it will act as a diuretic instead.

If the urine is nearly suppressed and there are premonitory symptoms of uræmic convulsions, you may use pilocarpine (the active principle of jaborandi). It may be given hypodermically or by the mouth. It is a powerful diaphoretic; it increases salivation, and is eliminated by the skin. It is a useful remedy to employ in urgent cases. We may also prompt the bowels by the use of podophyllin, and add to it the mild chloride of mercury. You may use croton oil, one-half or even one drop for a child three or four years of age. It will have a marvellous hydragogue effect in cases of uræmic convulsions.

To recapitulate: Let us not endeavor to break up an attack of scarlet fever, but rather be content with enforcing rigid preventive, hygienic treatment, using mild measures in mild cases; simply controlling the febrile action and temperature; supporting the patient; preventing complications, and curing them when they occur.

THE Annual Meeting of the American Surgical Association was opened with an address by the President, Professor Hunter McGuire, on the 11th instant, in the city of Washington. A report of the proceedings will appear in the next issue of the *Medical Times*.

ORIGINAL COMMUNICATIONS.

DIPHTHERIA.

Read before the Somerset County (Maine) Medical Association

BY A. E. FARNHAM, M.D.,

President of the Association.

LAST spring, during the month of April, diphtheria broke out in the village of East Madison, and for about three months the disease was endemic and raged with great fury. There had been no cases of the disease in the place for several years, and none was known to be about when the fatal malady made its appearance. It was limited to the village, and although people came to the place to trade, and in some instances to nurse the sick, no case occurred outside. The village and town had always been remarkably free from sickness, and there had been no prevailing disease prior to the outbreak. The sanitary condition was good, and the condition of things the same as usual when the disease made its appearance. At my request, Dr. A. G. Young, of the Maine State Board of Health, made a visit to the place, and after a careful investigation declared that the sanitary condition of the village was good and about the same as other small villages in Maine. Why we should have such a fatal form of the disease, and why it should rage as it did, neither Dr. Young nor any one else could tell. But rage it did, and spared neither old nor young. Death followed death till home after home was filled with mourning and the inhabitants were well-nigh panic-stricken. Physicians from far and near were called, but the disease swept on unchecked, and seemingly uninfluenced by treatment. It finally disappeared as suddenly as it came; but what waste of life it had wrought!

I had attended diphtheria in my practice, and seen much of it in city and country, and knew it was a fatal disease in many cases, but must say that, if I learned nothing else during this last terrible siege, I have learned to dread and fear diphtheria.

Just prior to the onset of the disease there were many cases of sore throat and tonsillitis, attended in some cases by considerable fever and prostration; and some of those thus affected afterwards thought that they had had the disease, "only a little lighter." But this was a mistake. When diphtheria is prevailing, these cases of sore throat are often called diphtheria. This sore throat is catarrhal, and is ushered in by a chill; the patient feels ill, and constitutional disturbances are experienced; but it is not to be recognized as a case of diphtheria unless you find an *exudation*, which is the great diagnostic feature. The sore throat may be ulcerative, but should not be mistaken for the membranous exudation of diphtheria. There is an occasional pseudo-membranous exudation in other diseases. For instance, croupous laryngitis resembles diphtheria as regards exudation, but not in the severe constitutional disturbances which are found in the latter, because croupous laryngitis is a local disease.

All diseases have a favorite place of attack: gout the big toe, typhoid fever the intestines, etc. Diphtheria attacks the mucous membrane, generally of the pharynx, but it may attack mucous membrane anywhere, as in the posterior nares or rectum, or it may attack an abrasion. A change takes place in the mucous membrane. There is congestion, but not active. The membrane is dark-colored, bluish rather than red. It may be purple; and it quickly becomes swollen. Changes take place first in the epithelium and subepithelium. This change is an infiltration of granular matter. The infiltration may go on beneath the epithelium, and involve the mucous and submucous tissue. The exudation is generally of a dirty yellow or leaden color, but may be stained by medicine or by matters vomited. This exudation is not a false membrane, but the different layers of epithelium or mucous tissue swollen and raised above the level.

What is this exudation? One author says it is granular fibrine, another holds that there is no cellular exudation. The exudation is of low power, and has no power of organization. The micrococci theory many of the best authors believe false. True, the parasites are found in the exudation soon after it has been removed, but are due to degeneration of tissue. They form in the exudation afterwards, as in other morbid conditions. Whatever the exudation is, it cannot be absorbed, but must be removed by a gangrenous or sloughing process. The exudation, when swept off or forcibly removed, returns. It should never be removed by force. Escharotics should not be used, for this rea-

son. If the infiltration be rapid and severe, so much tissue may break down and become gangrenous that death may result from septicæmia.

Early in the disease there are important blood-changes. The spleen becomes soft, liver congested, stomach disturbed, and there are changes very like typhus fever. I believe the disease is contagious in a degree, and I believe it is spontaneous. I formerly believed that poisoning took place from the exudation; but if it does take place in this way, I am now convinced that it is not always so. The disease is constitutional before it is local. The poison is introduced into the system through the lymphatics. The symptoms are best considered under two heads, constitutional and local. The constitutional symptoms, like the local, may be mild or severe. The constitutional symptoms do not always correspond to the local symptoms in mildness or severity. When diphtheria is ushered in with a chill and severe symptoms, it generally terminates quickly. There is often paralysis of the pharyngeal muscles, and when an attempt is made to swallow food or drink it is forced out through the nose. The popular belief is that the throat is filled up; but this is not so. It is not on account of the obstruction in the throat, but on account of the paralysis of the pharyngeal muscles.

As this disease descends into the larynx the symptoms become grave. The voice changes; it becomes hoarse, and finally dwindles to a whisper; the breathing becomes stertorous, and diphtheria, malignant and terrible, stares us in the face. There is difficulty at first of inspiration, and after a little, as the disease advances and descends into the throat, there will be difficulty of expiration. Some cases, instead of beginning in the pharynx, commence in the larynx; but it quickly spreads to the tonsils and pharynx. It is different from croupous laryngitis. There is an exudation, and around this exudation there is a red line. Whenever there is exudation, sooner or later there is enlargement of the surrounding glands. When resolution takes place, the exudation curls on its edges and is removed by a sloughing process, and under this patch is seen the new cellular exudation. There is a rise of temperature at the outset, but the fever quickly subsides. The temperature is a poor guide in this disease. The pulse is of vastly more importance in making a prognosis in diphtheria. There are no stages in diphtheria, no critical days, etc., as in some other diseases. It follows no regular laws. The diphtheritic poison may be so strong, so severe, that the vital powers are overwhelmed, and sudden death is the result. Some cases live but two or three days; others live weeks, and may finally recover. It all depends upon the amount of poison in the blood. When the tongue becomes dry and brown, and the patient sinks into a typhoid condition, death may result from septicæmia. An irregular pulse is a very unfavorable symptom, and when I find it I am cautious about making a favorable prognosis, even if the patient does not appear very ill. Of course, when the exudation enters the larynx, trachea, or bronchial tubes the case is hopeless.

I shall not discuss the value of tracheotomy in such cases. It is not easy to obtain the consent of relatives to have such a step taken. In the country, tubes of proper size may not be at hand, and if the operation is too long delayed it is useless to think of it. In the cities, where surgical instruments and intelligent assistance are at hand, I have no doubt that many lives could be saved by tracheotomy. But, as before stated, the pulse is the great study in this disease. It is the physician's best guide. A rapid pulse does not necessarily make the prognosis grave, but it does when it is irregular. Vomiting at the commencement of diphtheria is not to be regarded as dangerous, but in the last stages of the disease is very serious. Not at the commencement of diphtheria is delirium to be regarded as dangerous, but it is serious after the disease has run awhile. When delirium occurs late in the disease, it indicates that the kidneys are affected. When the exudation becomes dark and black, the case is dangerous. The brown tongue, the stupor, the typhoid condition, the evidence of overwhelming poison, herald the approach of death. In diphtheria there is danger all around us, on every side, from beginning to end. The patient may apparently be getting along well, and you may think the case on the gain,—friends may all be encouraged and hopeful,—but a few hours may make a great change in the sick-room. This terrible poison may suddenly overwhelm the vital powers, and death will swoop down and snatch its victim from before your very eyes.

There are two great dangers in diptheria: closure of the larynx and septicæmia. There are sequelæ to diphtheria which challenge attention. The most common is paralysis. This shows itself in the pharynx and muscles of the throat. There is difficulty in deglutition and a change in the voice, which has a characteristic nasal twang. This is due to paralysis of the pharyngeal muscles. Oftentimes there is paralysis of the lower extremities, and the patient is unable to stand, or he walks in a weak and unsteady manner. Endocarditis may follow diphtheria.

We often hear of some physician, but more often of some irregular practitioner, who has attended a great many cases of diphtheria and never lost a case. This is disgusting to any regular, or indeed to any intelligent physician who has had experience with malignant diphtheria. If one calls every case of sore throat or tonsillitis or pharyngitis diphtheria, he may be able to boast how many cases he has cured. A case of membranous croup need not be mistaken for diphtheria, because the attack is more sudden and the constitutional symptoms are lacking.

As regards the prognosis in diphtheria, it might as well be confessed that it is a very fatal disease. In epidemics nearly fifty per cent. will die. The first of an epidemic is the most fatal. After a while the disease seems to lose in a great measure its malignant character. The cases grow milder, and after the hardest of the epidemic is over the cases are simply diphtheritic sore throat. There are patches in the throat, and the patient may be quite ill for a few days, but there is not the terrible depression nor severe constitutional symptoms found in real diphtheria.

As regards treatment I shall not say a great deal, preferring to have this part of the subject discussed by the members of this Association in order that I may obtain their ideas and opinions. In the fatal epidemic through which I have just passed I have used both local and constitutional treatment. But the more experience I have had with the disease, the more I have relied upon constitutional treatment. A patient with diphtheria should be put to bed and kept there constantly until the disease has ended, even if the case appear to be a mild one. This should be insisted upon. I believe much danger is incurred by allowing a patient who feels pretty well to get out of bed and move about the room. The room should be well ventilated and kept at a temperature of 65° or 70° F., and the air kept moist by having water upon the stove, or by some way of getting steam into the room. The patient should not be required to open the mouth too often. The throat should be exposed only when necessary. Cleanliness should be insisted upon, also frequent washing of the patient and clothes. Antiseptic measures should be carried out, and the sick-room frequently disinfected. No one should be allowed to go into the room except those needed to care for the patient. I allow my patients to wear a piece of pork around the neck, as it is mildly counter-irritant and is a domestic remedy much in vogue. I prefer salt and lard to the pork, and regard a flannel saturated with spirit of camphor and olive oil as better than either. I have little faith in external applications. Blisters should not be used. The danger is increased by blisters anywhere. Ice may be allowed, and small pieces held in the mouth are very acceptable to the patient. Ice may delay suppuration, but does not arrest it. Warm applications are good because they hasten the suppuration, and this is what we want. The forcible removal of the exudation or patch should be avoided. It is like tearing off the scab from a sore. The membrane or tissue beneath the patch must heal before the patch comes away. When the patch is loose or hanging by shreds and annoying the patient, it may be removed to render him more comfortable and prevent swallowing. The use of escharotics I do not believe judicious. Tincture of iodine and nitrate of silver should seldom, if ever, be used upon the throat in this disease. The time-honored remedy, chlorate of potassium, often does good, and is worthy of further trial. After a few days, in some cases, I think that the use of gargles is harmful. The effort made strains the muscles and puts the case back. In such cases the potassium chlorate tablets, allowed to dissolve upon the tongue, answer the purpose well. Small powders of chlorate of potassium, with pulverized gum arabic or borate of soda, may be used by directing that they be placed on the tongue and the saliva swallowed. Carbolic acid and bromine appear to benefit certain cases. The sulphocarbolate of sodium works like a charm in others. Steaming

with cubebs or a little lactic acid in the hot water relieves the pain in the throat and dislodges the mucus and phlegm. The inhalation of medicated vapors and the use of sprays and atomizers should be resorted to, and especially when the patient cannot successfully gargle the throat. The fluid extract of jaborandi, given in often-repeated doses, will often keep the throat from filling up with false membrane. If a case of diphtheria is seen early, a laxative dose of calomel is often attended with good results. Those who believe in the antiseptic theory of treating disease give the bichloride of mercury. But of all the remedies in diphtheria, iron stands at the head. The tincture of the chloride is the preparation used. It acts in diphtheria, as in erysipelas, as a powerful restorative to the blood. Alcohol in some form may be used from the first, and in some cases is a sheet-anchor, inasmuch as it sustains the strength of the patient. Quinine, in my opinion, in even small doses, does harm, and should not be given.

It is of great importance to feed the patient and keep the nutrition as good as possible. Milk, sometimes containing lime-water, may be given as often as the patient will take it. Meat-broths, eggs beaten up with whiskey and milk, gruel, and any nourishing drink, should be administered as often as every two or three hours, night and day. Often, if the patient is asked if food is wanted, he will reply in the negative. The taste is destroyed, and there is no desire for food, and eating or drinking is painful. Therefore the nurse should not depend upon the sick one to call for food, or even ask him about the matter, but use her own judgment if the attending physician has not left directions; she must carry the nourishment to the patient at regular times, the same as the medicine, and insist upon its being taken.

TUBERCULOUS TUMORS OF THE CEREBELLUM IN A CHILD FOUR YEARS OLD—AUTOPSY AND MICROSCOPICAL EXAMINATION.

BY G. E. DESCHWEINITZ, M.D.,

Prosector of Anatomy in the University of Pennsylvania; Ophthalmic Surgeon to the Children's Hospital, Philadelphia; Ophthalmologist to the Orthopædic Hospital and Infirmary for Nervous Diseases.

LIZZIE D., aged 4, was admitted to the Children's Hospital, March 17, 1886, for arthritis of the right elbow and on account of a train of symptoms then supposed to be the result of poor food and general neglect. The following family and personal history was obtained. The father was a peddler, and, except for occasional attacks of rheumatism, a healthy man. The mother had been a hard drinker, and six months previous to this date had become insane. Six children composed the family. The eldest was fifteen, but her prematurely-aged face made her appear many years older. One brother had died of Pott's disease. This child, the youngest, had always easily contracted colds, and eighteen months ago an injury caused the existing arthritis of the elbow. Two months before admission the child began to lose the power of her lower limbs, and when admitted she was unable to stand or walk, but the ability to move the limbs remained. At this time no marked ocular symptoms were noted by the attendants, but gradually it became evident that vision was failing, and a thorough examination revealed the following facts. The pupils were of medium and equal size; ordinary objects were not noticed, but a bright light was perceived. The optic disks were oval, white, and filled in; the nasal edges softened and veiled by a grayish haze; the veins were tortuous. The appearances were those of a beginning consecutive atrophy. There was no anæsthesia; the myotatic irritability was not increased. The appetite, digestive functions, and mental faculties were normal. Examination of the urine revealed that it was alkaline, and on standing crystals of ammonio-magnesium phosphate were deposited; sugar and albumen were absent. For a time no new symptoms appeared, but about the beginning of June the child began to fail rapidly.

On June 17 vomiting and obstinate constipation were marked symptoms, and on June 21 convulsions, tetanoid in type, set in and were more or less constantly present until death took place. On the evening of June 22 the breathing assumed the character usually described as Cheyne-Stokes respiration, and about four o'clock in the afternoon of June 23 the child died.

Autopsy.—No unusual external appearances. *Thorax.*—The heart and pericardium and the right lung and pleural cavity showed no abnormalities. On the left side there were extensive pleuritic adhesions from apex to base. The upper lobe of the left lung was small, shrunken, completely

bound down, and, on section, cut like fibrous tissue. *Abdomen.*—Position of viscera normal. The mesenteric glands were slightly enlarged. In the left kidney there was a wedge-shaped caseous (tubercular) mass. In the remaining viscera no gross lesions were discovered. *Brain and its Membranes.*—There were no changes in the membranes over the upper surfaces of the hemispheres. The anterior surface of the brain was flattened, and incision into the lateral ventricles allowed the escape of a large quantity of clear fluid. At the base of the brain the pia mater was injected and spots of opacity were noted, but there was no lymph or pus. In the right cerebellar hemisphere there was an oblong, yellowish-white tumor, six centimetres long, that penetrated the tissue of the cerebellum to the depth of three centimetres, and whose inner end had pushed its way into the central portion of the middle lobe. In the outer part of the left hemisphere a precisely similar though smaller tumor, two centimetres long and one and a half centimetres deep, existed. Well-marked distention of the optic-nerve sheaths, immediately behind the globe, was present.

Microscopical Examination.—The *optic papilla* was distinctly swollen and contained many nuclei. The cross-sections of the vessels showed that they were not shrunken, while their walls revealed some leucocyte infiltration. The retinal layers were displaced. *Optic nerve.*—The sheath of the nerve was greatly distended, and the intervening space occupied by a net-work of nucleated fibres and many free cells. The fibrous septa which separated the nerve-bundles were thickened, and the nerve-bundles themselves were infiltrated with numerous nuclei, while the separate fibres were granular and indistinct. In the fasciculi of the periphery the most marked atrophy was seen. The retinal vessels were oval in cross-section, but normal in appearance. The same pathological changes obtained throughout the entire length of the nerve, and existed also in those portions of the *optic tracts* which were studied. These were, unfortunately, only a very small part of their terminations in the commissure. In a study of some sections of the *chiasma*, especially such as were stained after the manner of Weigert, there certainly seemed to be a very distinct band of fibres across the anterior border of the commissure which connected the optic nerves on either side. This band would correspond to the inter-retinal fibres the existence of which has been denied by recent anatomists.

The tumors.—These were tuberculous masses which had undergone caseation. Scattered through the finely granular tissue of which they were composed were numerous giant-cells, either well formed or affected by the general caseation. Dr. William M. Gray, of the Army Medical Museum, to whom I am indebted for the preparation of many beautiful sections from these specimens, has succeeded in demonstrating tubercle-bacilli in the larger tumor.

In the *pia mater* of the base of the brain the perivascular lymph-sheaths were fully distended with small round cells. In addition, there were extensive extravasations of blood-corpuscles and a general infiltration with young cells. Sections double-stained with carmine and sulpho-indigotate of potash showed particularly well this beginning tuberculous inflammation of the pia mater.

Lung.—In the upper lobe of the left lung very little true pulmonary tissue remained, and the alveolar walls of that which did exist were densely infiltrated with small round cells. The remainder of the lobe was composed of wavy fibrous tissue, through which, sometimes sparsely, sometimes in rich collections, a round-cell infiltrate was scattered. It seemed to be a tuberculous tissue undergoing fibroid change.

It seems useless to do more than report this case as an interesting example of tuberculous disease of the cerebellum. I will, however, briefly recapitulate for convenience the main points.

1. The pathological lesions were: two tubercular tumors in the cerebellum, the larger involving the middle lobe; beginning tubercular meningitis of the base of the brain; optic neuritis, and later consecutive atrophy of the disks; old tuberculous disease of the left lung; a caseous mass in the left kidney, and arthritis of the right elbow.

2. The symptoms were: the general appearances as if the patient had been underfed and neglected; progressive failure in the power of the lower limbs, without paralysis; blindness from the results of descending neuritis; at first normal

appetite and digestive functions, but later vomiting and obstinate constipation; alkaline urine, which deposited triple phosphate crystals; convulsions, tetanoid in type; and for some hours before death Cheyne-Stokes respiration.

1330 Spruce Street, Philadelphia.

REPORT ON THE PROGRESS OF DERMATOLOGY.

BY ARTHUR VAN HARLINGEN, M.D.,
Professor of Dermatology in the Philadelphia Polyclinic.

IN the present report it is intended to give a general review of the progress of dermatology during the past year, as exemplified in the special journals of this country, France, and Germany. The more important contributions made to the general medical journals during 1886 which have not already been noticed will form the subject of a later report.

The address of the President of the American Dermatological Association at the annual meeting last September has attracted general attention, both from the evidences given of advance in the specialty and also from the outspoken manner in which the claims to a fuller recognition of this branch of medicine are advocated.

Ten years ago the Nestor of American dermatology, Professor White, of Harvard University, said, "Every day we see in the out-patient department and elsewhere cases which we know are requiring attention they will not, cannot receive at home; cases which, without restraint and peculiar management, last indefinitely and spread disease; cases which entail horrible consequences upon others; all of them sure of more rapid and certain recovery if they could receive such hospital care; some of them as surely doomed to years of misery and even speedy death because they do not obtain it. Those who, from love to their fellow-men or pity of their bodily woes, have left large endowments for their care in sickness, they who make generous appropriations from the wealth of States and cities for the treatment of disease among the poorer classes of society, certainly have intended no such arbitrary distinctions. It is not they who have ordained that a fever or a fracture shall have the best chance of recovery by proper nursing and the most eminent professional attention, while an inflammatory or destructive process of the integument shall be debarred from both. There is neither reason nor justice in such action, and they who control the government of such institutions have much to answer for for such unequal distribution of hospital charity."

". . . As now managed nearly everywhere among us, these institutions refuse to a large class of sick persons the benefit of hospital residence either wholly, or offer them, if received, not, we may fairly say, the best medical skill it is in their power to procure."

These stinging words are, unfortunately, almost as true to-day as when they were uttered ten years ago. We have only to look at our hospitals in Philadelphia to-day to see how inadequate—or rather how entirely absent—are all means for the treatment of all diseases of the skin, even such as scabies and pediculosis, so easily cured and yet so torturing to their wretched victims; and how indifferent apparently are their managers to the obtaining of skilled physicians to treat this class of diseases.

The address of Dr. Wigglesworth points out the various needs of dermatology and suggests the means for their attainment, and is altogether a valuable document not only to the specialist in skin-diseases, but to every intelligent physician desirous of measuring the aims and methods of a large and intelligent body of scientific men in his own profession.

When we cast a glance over the general field of dermatological literature for the year 1886, we are somewhat surprised to observe how great attention has been given to a single class of diseases,—namely, the new growths, and particularly lupus vulgaris and leprosy. In the German journals, out of thirty-two original articles (aside from those on therapeutics), no fewer than fifteen were upon the diseases of this class, seven of which were upon the diseases mentioned. In the French *Annales*, out of thirteen articles five were upon new growths, of which one each was upon the diseases mentioned. In the *American Journal of Cutaneous and Venereal Diseases*, on the other hand, out of thirty-two articles only one could be taken as belonging to this class, while fourteen belonged to the class of inflammatory affections.

This contrast shows both the greater

frequency of such affections as lepra, lupus, tuberculosis of the skin, and syphilis abroad as compared with this country, and also the greater interest manifested in France and Germany in the study of questions of etiology and pathology, the attention of our physicians being somewhat more occupied with what are called "practical" questions.

LEPROSY.

The question of the nature and treatment of leprosy continues to occupy much attention both in Germany and in France. In Germany, Unna has been foremost in both pathology and therapeutics, and we most cordially second the wish expressed by another writer, "that his initiative and his arduous endeavors may succeed in substituting for the indifference with which leprosy with all its extensive and increasing diffusion is generally regarded a warm interest in its investigation and cure."

In 1885 Touton published an article on the localization of the bacillus lepræ, maintaining that its seat was in the cells. The peculiar nidus for the development and colonization of the lepra-bacillus is the protoplasm of the cells, and the greater number of all bacilli lie, as has always been supposed, in larger or smaller agglomerations within the cells. These bacillus-agglomerations are therefore not themselves cells, but only parts (inhabitants) of cells. Those agglomerations of bacilli found at large were originally contained in cells. To this Unna rejoined in an article too highly technical to reproduce here even in abstract, and ended by asserting categorically that "lepra-bacilli are never contained in the cells of the tissues."

At the beginning of last year Unna returned to the question in a supplement to the *Monatshefte für Dermatologie* for January. In the introduction to his article he says that we can scarcely find in human pathology a second example of so lavish an abundance of parasitic life in organs remaining so comparatively healthy, and for that reason we can judge better here than under any other circumstances of the physiological relationship between the bacilli and the human tissues.

After giving his method of histological procedure, Unna goes on to discuss the distribution of the bacilli in the skin, their occurrence in the blood-vessels, the convoluted glands of leprous skin, the examination of tissue-juice, where he finds no cells, but plenty of bacilli and agglomerations of bacilli in confirmation of his former views; asks the question, Has the bacillus lepræ a movement of its own? which he answers tentatively in the negative, or at least as "not proved;" the behavior of the bacillus in pus, which he thinks causes atrophy; the nature of the "vacuoles," which he considers thin portions of the cell-agglomerations; and finally winds up his admirable monograph with the following conclusion:

The leprous tubercle is an infectious tumor, to be included among the infectious hypertrophies. Among these it occupies a very peculiar position in that its chief bulk is made up of micro-organisms; it is therefore to be regarded as a bacillar tumor, in which the tissue-changes play a subordinate part.

Unna intends to return to the subject later, in order to discuss the normal issue of this tumor, the atrophic changes in the bacillus, as well as in the cutaneous tissues.

In the same supplement to the *Monatshefte* Lutz adds a brief paper upon the morphology of the micro-organism of lepra.

The question of the contagiousness of leprosy is one of the highest interest, but it seems as far from settlement as ever, in spite of the numerous contributions to the subject which have appeared during the last few years. Two contributions have been made to the subject, however, which are worthy of a brief note. One is in the form of a series of experiments by George Thin, which were undertaken under the auspices of the British Medical Association, but which we find published in the *Vierteljahrschr. f. Derm. u. Syph.*, vol. xiii., 1886, p. 337. Thin cut out small pieces of leprous skin proved such by microscopic examination, and implanted them in the cornea and the skin of healthy apes, cats, etc., but with a negative result, since the animals perished from intercurrent disorders in no way connected with the inoculation. Thin thinks the experiments had not a fair chance. When it is considered how long a time elapses between the perhaps temporary stay of a human being in a leprous locality and the outbreak of the disease in his body after his return to a healthy region, the failure of inoculations in animals must not be re-

garded as conclusive until such animals shall have been kept a series of years under observation.

The second paper bearing on this subject is that of Paulsen (*Monatshefte für Dermatologie*, vol. v., 1886, p. 8), which is simply a brief history of a single case, but which is of especial interest because of the demonstration of the presence of bacillus lepræ in some of the secretions. The patient, among various symptoms, showed narrowing of the upper air-passages by thickening of the lining membrane, which was pale red and covered with muco-purulent secretion. On the bony septum nasi were prominent ulcerating tubercles. Other ulcerative lesions of the mucous membrane of the naso-pharyngeal region were also present. The mucus exuding from these localities was examined by Paulsen, who found bacillus lepræ in large numbers. In the detritus from the ulcerating tubercles in the nose bacilli were found in agglomerated masses looking like cells, but distinct entirely from the cells of the tissues. This observation points out one way at least in which leprosy can be conveyed.

Although belonging to an earlier date than the beginning of last year, Unna's contribution to the therapeutics of leprosy is of such importance in this connection that it may well be added here. It is from the *Monatshefte* for 1885, and is concerned with a well-marked case of leprosy which came under Unna's care and was treated successfully. From his experience with this case, Unna concludes that tubercular leprosy, even when generalized and of over a year's duration, can be cured in a comparatively short time by means of combined internal and external treatment actively carried out. The most useful agents are those called by Unna reducing, and chiefly sulpho-ichthyolate of ammonia, chrysarobin, pyrogallol, and resorcin. Ichthyol is to be employed in strong preparations externally, while the inward dose averages fifteen grains a day. Chrysarobin and pyrogallol are too strong for most skins. Resorcin is useful in a twenty-per-cent. ointment, or, better still, in the form of a plaster. It has the advantage of not smelling badly, of not irritating the skin, and of not irritating the eyes. Pyrogallol is a highly energetic anti-leprous remedy. A five-per-cent. ointment is strong enough in general, but when the skin is resistant a stronger ointment or plaster can be employed. Chrysarobin is the best topical application in leprosy, but especial precaution must be used against its irritating influence upon the ocular conjunctiva. In robust persons chrysarobin may be employed on the body and limbs, avoiding the face and hands. In weaker patients the other remedies should be employed until all has been obtained from them that they will give, and the chrysarobin only used in the most rebellious points of disease.

As a corrective against the toxic effects of the various drugs used, particularly the pyrogallol, Unna recommends the internal use of hydrochloric acid in as large quantities as possible, to diminish the alkalinity of the blood. Salicylic acid plaster and carbolated mercurial plaster may be used as adjuvant local remedies.

Finally, Unna is disposed to think that the radical external cure of the leprosy in the case cited was really internal as well as external, for not only was the patient's general condition markedly improved during the treatment, the nutrition returning to its normal state, but this improvement was manifestly due to the internal administration of the salts of ichthyol, the action of which, combined with its external use, is "gently anti-leprous." The remedy can be used indefinitely, without injury to the patient, until the leprous germs are entirely destroyed. As to relapses, these are no more likely to occur than in syphilis, and, unlike this disease, the treatment can do no harm, however prolonged.

LUPUS VULGARIS AND TUBERCULOSIS OF THE SKIN.

Dr. Felix Bloch, assistant to Professor Neisser, publishes an interesting article in the *Vierteljahrschrift* (Heft ii., Jahrg. xiii., p. 201) on the etiology and pathogenesis of lupus vulgaris. Doutrelpont in 1883 first pointed out the existence of a bacillus in lupus, and his investigations were confirmed by others, Koch asserting the identity of this bacillus with that of tuberculosis, and the consequent relationship of the two diseases. A lacuna in the evidence exists in the fact that lupus cannot be produced by inoculation with the bacillus tuberculosis, and perhaps also in the fact that the bacillus of lupus is not found in such quantity as that of tuberculosis in its specific locality, but, on the

contrary, is infrequent even in lupus tissue. Moreover, Kaposi, the most important opponent of this view, brings forward more than six hundred cases of lupus treated by himself, in very few of which could any scrofulous element or history be found, as well as hundreds of scrofulous patients who were not affected by lupus. Moreover, there is such a thing as a true tuberculosis of the skin.*

This argument from clinical observation Bloch endeavors to meet. To do this he combines the statistics of Neisser's clinic at Breslau with those of Raudnitz of Prague and Pontoppidan of Copenhagen. In Neisser's clinic and private practice combined one hundred and forty-four cases of lupus occurred between Easter of 1877 and November of 1885. These are carefully analyzed in Bloch's paper, and compared with the other statistics as to the sexual relations of lupus, time of first appearance, localization, previous disease, complications, heredity, and, finally, the relation between lupus and scrofulosis. With regard to the very interesting statistics given under the earlier of these heads, want of space forbids us to concern ourselves. A few words, however, may be said with reference to the last point.

"If," says Dr. Bloch, "lupus is a tuberculous disease, we must expect frequently to meet with tuberculous lesions of other organs in connection with lupus of the skin." Recent French writers, as Quinaud and Bésnier, assert this to be the case. Demme also, among the Germans, asserts the same thing, and all bring forth statistics to prove their view.

Bloch arrives at the conclusion that three-fourths at least of all lupus patients suffer from other kinds of tuberculous affections, and in one-fourth of these the tuberculous disease showed itself before the outbreak of lupus.

Leloir, in a clinical lecture (*Annales de Dermatologie et de Syphiligraphie*, t. vii., 1886, p. 328), gives the account of a case, occurring under his own observation, where a lupous nodule of the hand became the origin of a tuberculous lymphangitis, with the production of scrofulo-tuberculous gummata along the track of the affected lymphatics, and, finally, as a result of absorption of tuberculous virus by the lymphatics of the upper limb, gave rise to pulmonary tuberculosis on the side affected. In other cases Leloir has observed reticular erysipelatoid lymphangitis, presenting itself under the form of "white erysipelas" ("scrofulous erysipelas"), appear to play a prominent part in the absorption of the virus. He gives his own statistics, and declares himself a firm believer in the fact that true lupus vulgaris is one of the forms of cutaneous tuberculosis.

Sachs (*Vierteljahrschr. für Derm. u. Syph.*, Bd. xiii., 1886, p. 241) gives the statistics of one hundred and sixty-one cases of lupus treated at the Heidelberg clinic, of which he was able to get an exact history in more than one hundred. The result of his examination agrees with Bloch's statements, particularly with regard to the frequent occurrence of lupus in connection with tuberculosis of other organs than the skin.

LUPUS-CARCINOMA.

That carcinoma may develop in and from lupous tissue has long been known, though the cases on record are few in number. Winternitz, assistant in Pick's clinic in Prague, adds notes of a recent case (*Vierteljahrschr. f. Derm. u. Syph.*, Bd. xiii., 1886, p. 770). It was that of a man, of 45, suffering with diffuse redness of the face, except the nose and forehead, and extending to the right ear, the neck, and the back just about the neck, the surface showing numerous lupus nodules and scars. Various patches of lupus could also be observed over other portions of the body and limbs. On the side of the face, not far from the malar prominence, was a tumor, which, being removed and examined, showed the microscopic appearances of carcinoma. Removal with the knife was followed by rapid healing, and six months later the carcinoma showed no signs of return, although the lupus continued to spread.

TUBERCULOSIS OF THE SKIN.

Riehl and Paltauf (*Vierteljahrschr. f. Derm. u. Syph.*, Bd. xiii., 1886, p. 19) describe an unusual affection occurring commonly on the back of one or both hands, and occasionally also on the extensor surface of the fingers or between the fingers, but rarely on the palm or on the adjoining portions of the wrist. The erup-

* Of course, lupus erythematosus is not taken into consideration, being an independent affection.

tion resembles a patch of lupus, being made up of dull brownish-red pea-sized to coin-sized papular lesions, often grouped in circinate or serpiginous forms, and spreading by the addition of new lesions on the periphery. As the lesion develops, a warty or papillomatous condition forms, particularly in the centre of the lesion, and occasionally superficial pustules form, so that the lesion takes on a crusted appearance, and when the crusts are removed pus wells up from sieve-like openings beneath. The lesion gradually dries up, becomes smooth and flat, and atrophied or scar-like in the centre, while the periphery may continue to develop.

The subjective symptoms are slight. At the height of the disease there is a feeling of tenderness on pressure, sometimes amounting to extreme sensitiveness. The progress of the disease is slow, with stationary intervals. It may be quite extensive, covering the entire back of the hand. More frequently months may pass without any perceptible alteration in the size of the lesion.

The diagnosis of tuberculosis verrucosa cutis must be made by regarding the course of the disease and the various lesions as a whole. Neither the red external ridge frequently covered with pustules, nor the papilloma with its horny covering above and deposits of pus at the base, nor the subsequent cicatricial condition, can be regarded as characteristic, although not occurring in any other affection in the same order and with the same clinical picture.

Lupus verrucosus always gives rise to circumscribed centres of infiltration in the form of brownish-red tubercles, characterized by their comparatively soft consistence and absence of acute inflammatory symptoms. In tuberculosis verrucosa cutis the circumscribed tubercles are absent, and each fresh exacerbation is accompanied by inflammatory symptoms. In addition, there is no tendency to ulceration of the older lesions, such as exists in lupus.

Inflammatory papilloma from injuries or badly granulating wounds are to be distinguished by their varied locality according to the injury, by the absence of inflammatory symptoms, and chiefly by the less acute course followed.

Papilloma following syphilitic lesions, with framboesia-like symptoms, may be distinguished from the affection under consideration by the thick infiltration about the borders and the characteristics of the syphilitic ulcer.

From lupus it is distinguished by the lesions disappearing under pressure, while the nodules of lupus show yellow under the skin as the finger is drawn firmly over them. In addition, lupus generally begins in the young, while the disease under consideration is one of adult life.

The inflammatory papilloma of the skin of Roser and Weil is quite different in appearance and locality.

Leloir's "Perifolliculite suppurée et conglomérée en placard" (*Annales de Derm. et de Syph.*, v. 1884, p. 436) closely resembles Riehl and Paltauf's affection, and they think is a variety of it. They also consider verruca necrogenica as a closely-allied affection.

Pathologically by histological arrangement of the tissues, as well as by the presence of the bacillus tuberculosis, the nature of the disease is settled and its name justified.

The treatment of the disease consists either in excision by the knife, scraping with the curette, or burning out by some appropriate caustic, as caustic potassa, either with or without previous scraping. The wound is afterwards to be healed up under pyrogallic acid or iodoform.

Chiari reports (*Vierteljahrschr. f. Derm. u. Syphilis*) an almost unique case of extensive tuberculous ulceration of the vulva and vagina. The patient was a married woman, of 30, who had never borne children. Dying of some intercurrent disease, Chiari had the opportunity of making a post-mortem examination. He found a large irregular ulcer, with infiltrated irregular, sharply-cut borders, on the right labium, running up to the clitoris and beyond, and extending into the vagina. The ulcer presented the characteristics of tuberculous ulcers, and several other similar lesions were found in the vagina and anus, with numerous enlarged and cheesy glands about the pelvic region.

The affection is to be distinguished from epithelioma and lupus. A microscopic examination showed abundant bacilli tuberculosis.

(To be continued.)

THE Committee on Arrangements announce that proper arrangements have been made to accommodate the various Sections of the International Congress in Washington.

TRANSLATIONS.

HYDATID CYSTS OF THE LIVER.—M. Baudouin in a late paper laments the tardiness of his fellow-countrymen in adopting the modern improvements in abdominal surgery, particularly in regard to the surgical treatment of hydatid cysts of the liver. This question was not seriously considered in France until it was brought before the Surgical Society in 1885.

Acupuncture, formerly recommended by Trousseau, is now rarely employed. Electrolysis, as advocated by Hernot (of Reims), is scarcely any more popular. Simple puncture of the cyst, puncture followed by the injection of some antiseptic fluid, multiple punctures, multiple punctures with incision, simple incision with drainage, and aspiration have all been employed and praised by particular operators, but none have given perfect and universal satisfaction. Boinet was the first to introduce the method of making simultaneously two punctures into the cyst by means of a curved trocar, which was left *in situ* for a few days, and then uniting these two punctures by means of a deep incision made with a bistoury. Boinet's method itself is not employed at the present time, but it has been revived and modified in the various methods of Simon, Verneuil, Kuster, and Hirschberg. Simon made use of *two* fine trocars, left *in situ* for a few days, and as soon as pus began to appear in the fluid evacuated from the cyst he laid open the sac with an incision uniting the two punctures made by the trocar, and injected it with some antiseptic fluid. Verneuil substituted two large trocars for the two fine ones of Simon, and instead of leaving them in place for a few days he used red caoutchouc sounds selected to fit exactly the punctured wounds. Kuster returned to the single curved trocar of Boinet, but modified it with a small opening at the middle of the convex portion. Then about the seventh or tenth day he replaced the cannula with a ligature gradually tightened down upon the parts lying between the two original punctures. Hirschberg endeavored to assure himself more positively of adhesion between the walls of the cyst and of the abdomen by making a number of punctures in the same straight line. We see in all these various methods of the past the tendency from the simple puncture to the free and open incision. It was reserved for Recamier at the age of sixty to assert the superiority of the latter over the former procedures.

Besides the well-known complications, such as urticaria, suppuration of the cyst, abscess of the liver, peritonitis, septicæmia, pulmonary embolism, as well as the possibility of auto-infection through the hepatic vessels, and even of sudden death from a vesicle lodging in one of the cavities of the heart (such a case is reported), the method by puncture does not assure us of a radical cure. We gain nothing by the use of the punctures before making the incision, but we lose much valuable time while waiting for the mural adhesions. It is quite as safe, if not safer, to make an incision, under proper antiseptic precautions, directly through the walls of the abdomen, and sufficiently large in the very beginning, as to have recourse to the production of adhesions by means of punctures.—*Le Progrès Médical.*

OBSERVATIONS UPON NARCEINE.—M. Laborde has been performing some experiments with a specimen of narceine furnished him by M. Duquesnel, who claims that it is almost absolutely chemically pure. At least it contains no morphine nor codeine. Given to animals, it produces a calm sleep, and is tolerated perfectly by the stomach. In doses of 0.02 centigramme in pill form, it overcomes insomnia. In half-centigramme doses it suppresses the spasmodic coughs of pertussis in children. Furthermore, the narceine furnished now by Duquesnel retains all its effective properties without having to increase the dose.

PHOSPHATE OF LIME is strongly recommended by Dr. Rebory for the night-sweats of phthisis. M. Potain, and after him Dr. Rebory, employ the tricalcic phosphate in doses of four grammes, often necessarily increased to eight and fifteen grammes. The excellent results obtained are attributed by Dr. Rebory to some special action of the medicine upon the perspiratory apparatus. It would seem more likely that the general improvement in the condition of the patient brought about by the phosphate should be the reason for the diminution in the night-sweats, one of the symptoms most indicative of the great debility of persons subject to phthisis. EDITORIAL.

THE IMMEDIATE CAUSE OF SUPPURATION.

THE infectivity of pus and the nearly constant presence of micro-organisms in the products of suppuration have been pretty well established by a large number of experiments. The absolute dependence of suppuration upon the presence of certain organisms has, however, not been generally accepted, although regarded as probable by a considerable number of observers. A recent research undertaken with the intention of determining this point may therefore be of interest to our readers.

Zuckermann, of the University of Kasan, introduced antiseptically into the tissues of white mice, dogs, and rabbits glass tubes containing sulphuric, nitric, acetic, hydrochloric, carbolic, chromic, lactic, and trichloracetic acids, caustic ammonia and potash, cupric sulphate in concentrated solution, mercury, bromine, chloroform, oil of turpentine, tincture of jequirity, croton oil, tar, oil of pine needles, and creasote. Out of thirty-nine experiments, nine only were followed by suppuration. In one of these the material introduced, sulphuric acid, had burnt through the skin, while in a second primary union of the wound had not followed, and secondary infection was possible. The seven remaining cases where suppuration had followed had been inoculated with oil of turpentine, tar, croton oil, bromine, and chloroform. The result in these instances is attributed to the non-sterilization of the materials used.

In another series of twenty-two experiments, pus was formed in only one case, in which non-sterilized croton oil was the inoculating material.

As regards the organisms found in pus, Zuckermann also instituted a series of observations. Microbes were found in the pus of thirty-eight abscesses examined. He collects all observations hitherto made by Rosenbach, Passet, Ogston, Hoffa, Triconi, and others, and, adding his own, finds that in four hundred and ninety-five abscesses staphylococcus pyogenes was present in seventy-one per cent., streptococcus pyogenes in sixteen per cent., and the two combined in 5.5 per cent. Other pus-organisms were found only exceptionally. In four inoculations of pure cultures of staphylococcus pyogenes aureus (by rubbing the same into the skin) an acute abscess was obtained in every case.

The conclusions reached by Zuckermann are that chemical, mechanical, or thermic irritants, if free from micro-organisms, cannot produce suppuration; that the cause of suppuration is one or more of the following organisms: staphylococcus pyogenes aureus, albus, and citreus, streptococcus pyogenes, and in putrid abscesses, bacillus pyogenes fœtidus; and that staphylococcus pyogenes is more frequently present in pus than the other organisms mentioned.

CONCERNING HYSTERIA FOLLOWING TRAUMATISM.

A work recently published, which receives notice on another page, treats upon the interesting subject of traumatic hysteria, or, more correctly speaking, of the hysterical manifestations, such as anæsthesia, paralysis, contracture, etc., following injuries of various sorts. In it the author, Dr. Paul Berbez, says, "The true cause of the hystero-traumatic phenomena is evidently a special condition of the patient's mind; the occasional cause (the traumatism) possessing only slight importance. This condition is not a pathologi-

cal rarity, and if surgeons would study the motility and particularly the state of the sensibility after the reduction of luxations, contusions, etc., they will very probably find a host of cases similar to ours." The symptoms are all of the kind common to hysteria, and are usually met with in patients who have had in their previous history more or less evidence of mental aberration, though this is not an absolutely necessary condition.

In order to study the mechanism of this nervous manifestation, the author takes into consideration three things: (1) the mental condition of the patient at the moment he receives the shock of the injury; (2) the immediate effect of the shock; and (3) the workings of the mind after the shock. "When we shall have studied these three sides of the question, we will without difficulty, we think, be convinced of the following fact: hystero-traumatic paralyses and contractures are in every respect similar to the paralyses and contractures, painful and non-painful, which may be produced in hypnotics by simple suggestion." Indeed, the paralyses are far from being due to either a neuritis or functional disturbance of the nerves: "the injury," he says, "whatever it may be, overclouds the perceptive faculties of the mind; the mind reflects upon the injury as the cause of the inability to move the part, accepts uncontrollably the suggestion of the absence of the injured member, and suppresses more or less abruptly all ideas which it possesses relatively to that member."

RESECTION OF THE PYLORUS.

THE fact that in more than half of the cases of gastric carcinoma the morbid growth is confined to the pylorus and its immediate vicinity, and that autopsies have shown that of the latter a very large number would be amenable to treatment by removal, fully justifies the operation of resection of the stomach in such cases, as first performed by Billroth. The grave prognosis of cancer of the stomach lends further warrant to the performance of this operation, and justifies exploratory laparotomy when there is even a fair probability that the malignant disease is circumscribed and in a favorable condition and position for removal.

In a paper read before the Academy of Medicine in Ireland last February, Dr. McArdle reported a case of this kind, in which, however, the patient died of exhaustion four hours after operation.* In reviewing the subject he showed from statistics of thirteen hundred and forty-two cases of cancer of the stomach that the disease was confined to the pylorus in eight hundred and two, of which four hundred and ninety-six cases were suitable for operation, as there was no involvement of neighboring glands or adhesion to adjoining viscera. He collated the records of seventy cases of pylorectomy, of which sixty-two were for cancer, with thirty-five deaths; eight for simple stricture, with three deaths. The higher mortality of the former was attributed to the frequency of extensive adhesions delaying the operation. These adhesions were studied with regard to locality, and it was found that, in two hundred and eighty-nine cases, the tumor adhered to the pancreas in one hundred and thirty-two, the omentum in eighty, the transverse colon in seventy-two, the liver in four, the small intestines in one. These points of frequent attachment should be taken as landmarks in digital exploration of the pyloric region. He considered operation justifiable under the following conditions:

1. In irritable and intractable pyloric ulcer leading to spasmodic stricture.

2. In simple fibrous stricture.

3. In circumscribed cancer without adhesion to pancreas or transverse colon.

---

* The Medical Press and Circular for April 20, 1887.

THE proprietors of the *Medical and Surgical Reporter* have made arrangements with Drs. N. A. Randolph and Charles W. Dulles to carry on the editorial and business management of the *Reporter*, and also the "Quarterly Compendium and Physician's Pocket-Record." The new arrangement went into effect on the 1st instant. The office of their publications has been removed to the northeast corner of Thirteenth and Walnut Streets, Philadelphia.

DR. J. MILNER FOTHERGILL, of London, will give three lectures on the "Modern Tendency of Disease" at his residence on June 2, 9, and 16, at 4 P.M. Members of the medical profession admitted on presenting their cards. Physicians from America will be especially welcomed.

THE State Assembly of Wisconsin has just appropriated fifteen thousand dollars as a contingent fund to be placed at the disposal of the State Board of Health, to be used in preventing the introduction of cholera into Wisconsin.

NOTES FROM SPECIAL CORRESPONDENTS.

LONDON.

CROONIAN LECTURES AND ORIGINAL RESEARCH—AMELIORATION OF DEATH-RATE IN ENGLAND—BRAIN-SURGERY—LECTURES ON FEVER—CONGENITAL DISLOCATION OF THE HIP—LAWSON TAIT ON SALPINGITIS—DRUMINE—FEES TO MEDICAL WITNESSES, ETC.

THE Royal College of Physicians of London has adopted a scheme for the management of the Croonian Trust which practically amounts to an endowment of research, on, it is true, a very modest scale. The annual income of the Trust Fund has been suddenly raised, by the falling in of leases, to a little over two hundred pounds a year. Up to the present time the Croonian lecturer has delivered three lectures, generally on some topic which had been a favorite study with him, and has received a small honorarium. Very often the lectures have been an excuse for writing a little book, and on the whole the general effect has been to give an opportunity for stating opinions and observations which would have found an outlet in clinical lectures, papers at societies, or addresses to associations or congresses, rather than to stimulate special original inquiries. Under the new scheme the lecturer's honorarium will be one hundred guineas, while a similar sum will be placed at the disposal of "a past or present Croonian lecturer" to "be employed for original investigation."

The "Annual Summary" recently issued by the Registrar-General affords strong evidence that the death-rate in the principal British towns is continuing to decline, and proof that it still remains considerably lower than that of the principal towns in any other country in the world. The death-rate in the twenty-eight chief towns, including London, was 20.9 per thousand. London itself has a death-rate below the average: in 1885 it was 19.8, and in 1886, 19.9 per mille. It is possible, however, that the true death-rate is a little higher than this, for it is six years since the census was taken, and there is some reason to believe that London has not been growing so rapidly during the last six years as during the previous decenniad. When all deductions, however, are made, there can be no reasonable doubt that the death-rate of London is very considerably lower than that of Berlin, Paris, or even New York. In a paper read to the Statistical Society, Mr. Noel Humphreys, of the Registrar-General's Office, has attempted to supply some new data with regard to class-mortality. He showed once more that the factor which controlled the rates both in population and classes was the child-mortality: thus, the annual death-rate among children under five years of all classes is believed to be sixty-one per mille, while in the "upper"—that is to say, wealthier—classes it is only about twenty-eight per mille. Mr. Humphreys was able to show that children born in the Peabody buildings have a better chance of surviving than those belonging to the same class but born in tenement-houses. This advantage is attributed to more effective sanitation; and if the term sanitation be understood in a wide sense, as expressing all the surroundings of an infant, the statement is indisputable. But if understood in a narrower sense as referring to drains, then it is only just to point out that it is the best—that is, the most steady, industrious, and intelligent—artisans who secure rooms in the Peabody dwellings, for which there is a keen competition, and that of course people of this kind take far more care of their children than the idle and intemperate. This opinion finds confirmation in the statement that the annual mortality among children under five years of age in the "general service class" is five times as great as among children of the same age in the "professional and independent class:" it would surely be to ride a hobby to death to

attribute the whole of this enormous difference to the influence of good or bad drainage alone, for this reason, if for no other, that the drainage and water-closets in the houses of the well-to-do are often as bad or worse than in the poorest tenements, where the Sanitary Inspector is omnipotent.

Mr. Victor Horsley has now published statistics of the first ten cases in which he has operated on the brain. The first operation was performed on May 25, 1886, the last on December 17, 1886. Two of the patients have died: one six months after the operation, from recurrence of the tumor; the other nineteen hours after the operation, which was performed as a last resort in a hopeless case of wide-spread paralysis due to cerebellar tumor. As to the wound, immediate union took place in every case, excepting of course the patient who died in nineteen hours. Mr. Horsley is thus fully justified in claiming that the operation of exposing and removing considerable portions of the brain is not to be ranked among the "dangerous" procedures of surgery. Before operating, morphine is administered, and it is found necessary to use very great care in the subsequent inhalation of chloroform, as dangerously deep narcosis may easily be induced, especially in children; the object of giving the morphine is to produce contraction of the cerebral arterioles in order to diminish hemorrhage. Special care is taken to fashion the scalp flap (for the old crucial incision is abandoned) so as to preserve either the temporal or the occipital arteries, and the periosteum is reflected along with the cutaneous structures. The bone is first of all attacked with the trephine, and the aperture in it is enlarged with a circular saw driven by a "surgical engine" (dentist's). After excising the tumor, cyst, or cicatrix, the flap is replaced and completely sewn up, except for one inch at the most dependent part, where excess of fluid can drain away, but a drainage-tube is not used. "I am more than ever convinced," says Mr. Horsley, "that the arachnoid, like the peritoneal cavity, may be trusted to absorb excess of fluid." Strict Listerism is observed for the first four or five days, or until the wound is healed.

The Gulstonian Lectures this year at the Royal College of Physicians were given by Dr. Donald MacAlister, of Cambridge. He is one of the few Senior Wranglers who ever took up medicine, and this course of lectures on the nature of fever makes one regret that fashion has led his predecessors almost without exception to become lawyers or schoolmasters. It would be impossible here to analyze the whole of his argument: it will suffice to indicate in general terms the position which he took up. He looked to the nervous system for an explanation of the phenomena of pyrexia: the body-heat is controlled by a triple nervous mechanism,—(1) the thermolytic or discharging mechanism; (2) the thermogenic or producing mechanism; (3) the thermotaxic or regulating mechanism. Relying on Dr. Hughlings Jackson's pregnant hypothesis, and employing his useful phraseology, Dr. MacAlister shows that the thermolytic is the lowest and the thermotaxic the highest level of development. In cold-blooded animals there is only a thermolytic mechanism; in young mammals the thermotaxic or regulating mechanism is imperfectly developed: a child's temperature is unstable, easily driven up, and almost as easily brought down. In ordinary fever there is a disorder not only of the regulating, but also of the thermogenic, the producing mechanism; when to this there is added a disorder of the discharging mechanism,—when, that is to say, the thermolytic lags behind the thermogenic, thermotaxy being also disordered,—then there is hyperpyrexia. Disorder of the regulating apparatus will produce paradoxical pyrexia, the so-called hysterical fever. In his discussion of the thermogenic apparatus, Dr. MacAlister relied to a great extent on the recent experiments of Professor Wood.

The two other courses of lectures at the Royal College of Physicians lend themselves even less readily to discussion here: both, it is true, dealt with questions of vast practical importance and great pathological interest; but both Dr. Broadbent (in treating of the pulse) and Dr. Priestley (in discussing an intra-uterine death) handled subjects which bristled with details and do not conduct to simple generalizations.

A series of specimens of the so-called congenital dislocation of the hip were exhibited at the last meeting of the Pathological Society here, and gave rise to an interesting discussion. On the whole, the evidence is very strong that the displacement is a congenital deformity due to imperfect development of the bones entering into the joint, but especially of the innominate. In all the specimens the acetabulum was deformed and had an imperfect lip. Dupuytren has recorded one case in which the deformity was transmitted from parent to child, and Mr. Howard Marsh during the discussion mentioned the case of a mother and child who both presented the displacement on both sides. It would seem probable, however, that in a few cases a true dislocation may be the consequence of an attack of the "acute arthritis of infants." When recovery takes place from this somewhat rare disease,—a very rare event, therefore,—the joint may be left in a condition of disorganization, which gradually settles down into a quiescent condition closely simulating congenital deformity. Lastly, it must be remembered that the condition might be congenital and yet not be due to improper development, but to intra-uterine inflammation.

Three cases in which a coil of wire was introduced into an aneurismal sac were reported to the Royal Medical and Chirurgical Society. In one case the aneurism was ab-

dominal, and laparotomy was performed. After about a foot of wire had been introduced it kinked, and the operation had to be abandoned; the patient died on the fifth day. In another case thirty-two feet of wire were introduced into an aneurism of the arch of the aorta; the patient died on the twelfth day. In the third case thirty-three feet of wire were introduced into a subclavian aneurism; the patient lived a fortnight. In all three cases the greater part of the clot formed would seem to have been loose, and in the third case mentioned it was very small in quantity. In the second case the skin became gangrenous, owing, it was thought, to the pressure of a pad, applied to check hemorrhage, on the firm mass of coiled wire in the sac. Altogether, not a very encouraging series of cases.

Dr. Joseph Coats, of Glasgow, related to the Pathological Society of London a remarkable case—the fourth or fifth on record—in which a hypertrophic goitre was accompanied by secondary growths having the same histological characters in other parts of the body. In this case there were several tumors of the skull, one of which was visible during life as a pulsatile swelling. The goitre had existed for sixteen years.

Mr. Lawson Tait has exhibited to the Pathological Society a series of preparations from fifty-eight patients operated upon by him during 1886 for disease of the uterine appendages. In all he had operated on sixty-three patients; but in four instances the specimens were not in his possession, and the fifth was lost. In the sixty-three cases there were only ten unmarried women; of these ten three had had gonorrhœa, two had been pregnant, and one had endured prolonged attempts to cure anteflexion with stem-pessaries. Mr. Tait described five causes for salpingitis: (1) simple catarrh, (2) exanthemata during puberty, (3) gonorrhœal infection, (4) post-puerperal pelvic inflammation, (5) arrested development of the uterus. With regard to the question of sterility he produced some interesting evidence. Of the fifty-three married women, twenty-three had never been pregnant, though married on an average ten years; sixteen had had one pregnancy followed immediately by pelvic trouble. Fourteen cases remained to be accounted for, all of them women who had had more than one child: eight gave a history of gonorrhœal disease not long before the operation, the average interval between this and their last pregnancy being three years. In the six remaining women the average period between the last pregnancy and the operation was fourteen years. These preparations appear to go far towards proving that in at least the vast majority of the cases the inflammatory affections of the "uterine appendages" which give rise to symptoms sufficiently severe to call for operation also produce structural changes which render the woman sterile.

Dr. John Reid, of Melbourne, Australia, has sent some samples of the alkaloid drumine, which he has obtained from an Australian creeping shrub, *Euphorbia Drummondii*. The plant has a very wide distribution in Australia, and as the mode of preparation recommended is remarkably simple, the alkaloid ought to be sold cheaply. The samples received by Professor Ogston, of Aberdeen, appear to have spoiled on the journey, so that the results were nil. Dr. Reid describes drumine as possessing anæsthetic properties as marked as those of cocaine: it does not cause dilatation of the pupil nor any constitutional symptoms when applied externally. Dr. Lewin has recently shown to the Medical Society in Berlin another local anæsthetic: it is described as a resinous extract prepared from *Piper methysticum*.

One of M. Charcot's patients has attracted a great deal of public attention in London by remaining in a condition of hypnotic lethargy for several weeks. He is a commercial traveller who appears to have come to England in the course of his business, and to have fallen among thieves on the day after his arrival. On the following morning he retired to bed and was believed to be asleep. On the fourth day of somnolence Dr. Keser, one of the physicians to the French hospital, was called in. He found him lying in bed, motionless, and apparently asleep; there was, however, some muscular rigidity, and general clonic spasm was easily produced by any sudden cutaneous stimulus. Dr. De Watteville ascertained that passive movements communicated to the arm (for the man had lost one in the Franco-Prussian war) or legs were continued indefinitely; that when the fist was closed the face assumed a pugnacious expression, and so on, according to the classical descriptions of Charcot. An epileptiform convulsion was produced by galvanization of the nose. At the end of a fortnight he began to show signs of spontaneous recovery, and on the sixteenth day he woke up. He was then suffering from aphonia and left hemianæsthesia and hemiplegia.

A great deal of dissatisfaction has been aroused in the medical service of the army by the issue of a warrant abolishing "relative rank." The officers of the service bear the titles surgeon, surgeon-major, brigade-surgeon, deputy surgeon-general, surgeon-general, and each grade ranked for precedence with certain grades in the combatant branch: surgeon-general with major-general, brigade-surgeon with lieutenant-colonel, and so on. This was called "relative rank." The new warrant abolished "relative rank," but, according to the solemn assurance of the Secretary of State for War, left the position of the medical officers unaltered, the term "relative rank" being, it was said, meaningless. This produced a state of things which "no fellow could understand:" so a new para-

graph has been promulgated restoring relative rank, if not in name, at least in reality, if it be a reality. The medical officers, however, refuse to be satisfied, "for," say they, "relative rank having been officially declared to be meaningless, it is not worth having."

The Medical Society of Wigan in Lancashire has taken up the subject of the fees paid to medical witnesses in the law courts. The scale of fees and allowances was fixed in 1858, and during the thirty years which have intervened a great many things have happened. The purchasing power of money has decreased, and facilities for communication have enormously increased. A practitioner is liable to be summoned to attend the court from day to day until the case he is engaged in is called on, and the only remuneration he can claim is one guinea a day, two shillings a night for lodgings, and second-class railway-fare. Setting aside the loss of practice, which is of course the most serious consideration, it really comes to this: that a medical practitioner summoned as an expert witness may easily find himself, when he has paid hotel and other incidental expenses, out of pocket. No reasonable increase in the scale of fees would completely compensate him for the loss of time and connection. The reform most urgently needed is an alteration in the mode of summoning medical witnesses, so that they should not be called upon to attend until they were wanted.

Some years ago the Grocers' Company, one of the richer livery companies of the city of London, established some scholarships in pathology, and from time to time one of the "Research Scholars" turns up in London to give some lectures on his researches. This year Mr. W. North, formerly Sharpey Physiological Scholar in University College, who has been studying malarial fevers in Italy, is giving a course of three lectures on their general history, the special local conditions found in the province of Rome, and on their etiology and pathology.

So many schemes for the improvement of "university education" in London have been floated within the last two or three years, and each one is so zealously defended by uncompromising advocates, that any spontaneous agreement appears to be out of the question. The Privy Council will probably receive some half-dozen applications for new charters, and under these circumstances it is expected that a Royal Commissioner will be appointed to report on the whole question, with perhaps special reference to the position of the medical schools in London.

DAWSON WILLIAMS, M.D.

DR. JOHN ASHHURST, JR., has been elected one of the Attending Surgeons of the Pennsylvania Hospital, to succeed Dr. R. J. Levis.

BALTIMORE.

THE MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND—THE YELLOW FEVER INVESTIGATION—POISONING BY OIL OF TANSY—"TWO COMEDIES"—ITEMS.

THE ancient Medical and Chirurgical Faculty of Maryland held its Eighty-Ninth Annual Convention last week, under the presidency of Dr. George W. Miltenberger. The sessions lasted four days, and a fair amount of good scientific work was done.

The financial condition of the faculty is not one of great prosperity. There is a deficiency in the treasury amounting to $276.27, partly owing to unusual expenses last year, and partly to the slowness of members in paying their dues. The total gain in membership during the last year was *one*,—a very unsatisfactory showing.

The library has been considerably increased during the year, there being now nearly ten thousand numbers upon the catalogue. With energy, tact, and hard work this number could, and should, be doubled. There are numerous scattered collections of medical books in this State which ought to find a home on the shelves of this library.

The State Medical Society of Pennsylvania sent a fraternal delegate in Dr. W. B. Ulrich, who was cordially received, and made a short speech full of good wishes from his associates.

Dr. Miltenberger, in his presidential address, reviewed the progress of medicine since he became a member of the faculty, nearly half a century ago. He discussed the relations of specialism and specialists to the general profession in a fair and dignified manner, and concluded with an eloquent quotation from a recent address of Sir James Paget.

The annual oration was delivered by Professor William H. Welch, of Johns Hopkins University, who chose as topic "Modes of Infection." He spoke of the advances made in demonstrating the bacterial nature of infectious diseases. From the positive knowledge we have of the modes of infection in some of these diseases, we are justified in concluding that all spread in a more or less similar manner. In cholera and typhoid fever the infectious agent is reproduced in the intestinal canal, and is given off from the body in the intestinal excretions. Dr. Welch believes that the cholera and typhoid fever poisons are capable of conveying the disease at the moment they are discharged in the intestinal excretions of the sick. No further development of the organism outside the body is necessary to render it infectious.

In the exanthematous diseases the infective agent is given off from the skin; in others possibly in the expired air. Hence, in preventing the spread of infectious diseases we must take account of the channels through which the disease-germs are thrown off.

Dr. Welch closed his excellent address as follows:

"What can be more instructive, or, indeed, more encouraging, than to witness the manner in which Asiatic cholera, during its present journey, has failed to secure any foothold in those European cities which are characterized by cleanliness and proper sanitary arrangements, although it has been repeatedly introduced into such cities? Those cities have secured their immunity not by spasmodic precautionary efforts after the entrance of the disease, but have done so by systematic and vigilant exertions during what may be termed the time of peace. Without wishing to pose as an alarmist, I believe that, with the announcement of the appearance of cholera at the borders of our country, the time has come to emphasize the fact that the only enlightened and civilized public policy is to put our house in order before danger is actually knocking at the door. We are only upon the threshold of a deeper insight into the nature of a class of diseases which have been more devastating to the human race than any upheavals of nature or any wars. They have left their imprint upon the political, the social, and the intellectual history of the world. One need not be of a too sanguine temperament to hope that our steadily-increasing knowledge will bear fruit, not only as has hitherto been the case in the prevention, but also in a system of causal therapeutics of these diseases. Then will be fulfilled that pious wish of enlightened practitioners of medicine in all ages of the world."

Dr. J. E. Michael, from the Section on Surgery, reported the details of nine cases of external perineal urethrotomy without a guide. The strictures requiring the perineal section were due, in one case, to perineal contusion, in five cases to sequelæ of gonorrhœa, in two cases to old fractures of the pelvic bones, and in one case to a recent fracture of the pelvis. All the patients recovered from the operation, although one died from tuberculosis six months after the operation, and one about a year after from cancer of the genital organs. Dr. Michael's experience has taught him that it is unnecessary to keep a catheter in the bladder after this operation.

From the Section on Practice of Medicine Dr. S. C. Chew reported upon Bergeon's treatment for consumption and upon strophanthus. In one case in which he had used the rectal injection of gas the patient was much improved. Strophanthus he regarded as a valuable addition to our list of heart-tonics.

The Section on Obstetrics reported through Dr. Wilmer Brinton, who presented a review of the recent progress in the art, and made a strong and timely plea for a more exact knowledge of obstetrical science and art by the general practitioner.

The Section on Therapeutics reported upon "Antipyretic Drugs and Cold-Water Antipyresis" through Dr. I. E. Atkinson.

Dr. A. B. Arnold read the report of the Section on Psychology and Medical Jurisprudence, selecting as his topic "Moral Insanity." He related a remarkable case which seemed difficult to account for except upon the theory that the moral obliquity of the individual was the result of disease. Such patients, he said, had a preponderance of inferior appetites, which they gratify. They are strangers to virtuous impulses. When taken to task for wrong-doing they give cunning reasons as excuses for their conduct. They evince a recklessness which would appall other people. They are against all laws. All they care for is the accomplishment of their own designs. When such people grow up they are averse to any regular occupation. Moral imbeciles exhibit a faulty judgment and a want of appreciation. The difficulty is to make a diagnosis between moral insanity and moral depravity. The history of each case must be the guide. If a man who has been a good, kind neighbor and moral man suddenly changes to a bad, cruel man, it may be assumed that this sudden change is morbid. A man who grew up good and then suddenly changed to bad must have done so as the result of disease. Men who are diseased morally may ruin themselves and families in consequence of it, and still retain their business and other traits. The difficulty of diagnosis in these cases is no greater than in the case of other obscure diseases. There are now quite a number of morbid phenomena which will be guides in deciding cases of moral insanity. As experts on the witness-stand physicians are liable to get into trouble, and it is their duty to give great study to such cases in order to give reasons for their conclusions. The difficulty in detecting such cases will be lessened in the future.

Dr. J. J. Chisolm, from the Section on Ophthalmology, described some simple methods for the ascertainment of ordinary eye-defects; and Dr. Randolph Winslow reported for the Section on Anatomy on Operations on the Round Ligaments of the Uterus.

Dr. Samuel J. Fort read a volunteer paper, in which he gave an interesting account of a remarkable case of abnormal memory. The individual is a congenital imbecile, and is now 43 years old. The memory is the only remarkable trait in this otherwise ordinary imbecile. He could compile a complete directory of those whom he had met during forty years of his life. He is very apt in remembering location and direction. Once passing over a road suffices to impress the surroundings indelibly upon his memory. What he reads is his apparently forever. Mention but the title of a book he has read, and he will repeat the entire contents. Mention an incident of a tale, and he will give the title and the rest of the tale. He has no

power to classify or generalize the things he remembers.

A paper on "Keratosis Senilis and its Relations to Epithelial Cancer" was read by Dr. George H. Rohé. He described keratosis senilis as small collections of epithelium variously distributed upon the face, trunk, neck, and extremities of elderly white persons. These collections usually occur in the form of roundish or irregular, slightly elevated, brownish or blackish patches. Sometimes they are dry and hard, but oftener the patch is greasy to the touch, soft, and easily scraped off with the finger-nail, leaving a moist or slightly-bleeding base. When rubbed or scratched off, the patches rapidly re-form, causing those affected much annoyance and often uneasiness by their persistence.

Physicians generally regard this as a trifling ailment, and pay no attention to it; but careful observation will show that not rarely the constant epithelial hyperplasia results in an atypical formation which eventuates in malignant ulceration. It therefore demands more attention from the profession than it has heretofore received. Prompt and appropriate treatment is not only desirable for its cosmetic effect, but may often save the patient much suffering and even prolong his existence.

When there is no induration present, the patches should be softened with some indifferent ointment, such as cold cream, vaseline, or cosmoline, then washed with soap and water to remove all the epithelial accumulation. Soft soap or *spiritus saponis kalinus* may be needed for this purpose. Afterwards an ointment containing sulphur and salicylic acid may be applied nightly, with success in most cases. The formula generally used by Dr. Rohé is—

℞ Acidi salicylici, gr. x–xxx;
Sulphuris præcip., ʒss–i;
Pulv. amyli triturat., ʒss;
Ungt. aquæ rosæ, ʒi.—M., ft. ungt.

If after six to eight weeks' persistent and regular use of this the epithelial accumulation returns, the patch should be lightly cauterized with caustic potash solution (1 : 2) or the thermo-cautery. If there is infiltration of the skin, the curette, thermo- or galvano-cautery, or electrolysis should be used, and the patch treated in all respects as a malignant growth.

The officers elected for the coming year are: Drs. I. E. Atkinson, President; C. H. Jones and James Carey Thomas, Vice-Presidents; W. F. A. Kemp, Treasurer; and G. L. Taneyhill, R. T. Wilson, Joseph T. Smith, and E. E. Mackenzie, Secretaries.

A communication from the chairman of the Finance Committee of the International Medical Congress was referred to a committee of twenty, who were empowered to collect subscriptions to aid in defraying the expenses of the Congress and forward the same to the proper officer of that organization.

An earnest appeal in favor of the Rush Monument fund was made by Dr. Rohé, the chairman of the local committee for this State.

Dr. George M. Sternberg, of the army, the eminent bacteriologist, who has been on duty as attending surgeon in this city for several years, has been appointed by President Cleveland as Commissioner to Brazil and Mexico to investigate the inoculations against yellow fever practised in those countries. This action was foreshadowed in the *Times* several weeks ago. Dr. Sternberg sailed for Brazil on the 4th instant.

At the last meeting of the Medical and Surgical Society Dr. Wilmer Brinton reported a fatal case of poisoning by oil of tansy taken with the object of producing abortion. The exact quantity taken could not be ascertained. The patient, soon after taking the drug, was seized with vomiting, followed by convulsions and collapse. She died within thirty minutes of swallowing the poison.

A case of poisoning by the same drug was related by Dr. Streett. This patient recovered. The symptoms were somewhat similar to those in the first case.

Dr. Frank Donaldson, Jr., who is well known to the profession for some excellent scientific work in physiology and laryngology, has lately made a venture in dramatic literature. He has written "Two Comedies: An Ill Wind, and An Abject Apology." The two works are published in an exquisitely-printed, vellum-bound volume from the press of Cupples, Upham & Co., of Boston. The dialogue is bright, the interest well sustained, and what there is of plot is wrought to a satisfactory climax in each instance. The little book will furnish a pleasant hour of relaxation from the burdens of professional work.

The new Marine Hospital, described in the *Times* some months ago, has been opened for the reception of patients.

The Woman's Medical College conferred the degree of M.D. on two candidates last Monday. G. H. R.

Baltimore, May 4, 1887.

PROCEEDINGS OF SOCIETIES.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Thursday, April 7, 1887.

The President, Thomas M. Drysdale, M.D., in the chair.

Dr. B. C. HIRST read a paper on

THE ETIOLOGY AND TREATMENT OF CASES OF SO-CALLED LATE INFECTION IN THE PUERPERAL STATE.

He said: The title of this paper is, I fear, too pretentious. Its object is merely the brief relation of four cases of so-called late infec-

tion in the puerperal state,—all, I believe, due to the same cause, all yielding to the same treatment, and conveying therefore a lesson of some little interest and value. The first case was a young primipara, delivered without difficulty after a moderately long labor. She left her bed on the eleventh day, having had no fever and having manifested no unusual symptom. Two days afterwards her cervix was exposed to view by means of a bivalve speculum, and a slight laceration was discovered, healing by granulation. The following morning, the fourteenth day after delivery, the patient was unwell; her temperature was 102°. Large doses of quinine were given, but the temperature rose to 103°, where it remained, with slight morning remissions, for two days. A more careful examination being made, it was discovered that the uterus was unusually large, that the os was patulous, that there was a foul-smelling discharge and considerable abdominal tenderness. The history of the case, with these symptoms, pointed to the retention of membranes, possibly a portion of placenta, and their subsequent decomposition, originated by the admission of air to the vagina and uterus by the use of the speculum. Acting upon this diagnosis, the uterine cavity was lightly scraped out with a dull curette, and a large quantity of decomposing decidua removed. This was followed by an intra-uterine injection of bichloride of mercury through a Bozeman's double catheter. The woman's temperature at the time was 103°. The following morning it had sunk to 99°, and within twenty-four hours was normal, and so remained.

The second case was also a primipara. The labor was terminated by the forceps. Upon the eleventh day the woman, although perfectly well until that time, had a morning temperature of 101°, rising in the evening to 102°. The uterus was found larger than it should have been. The os was patulous, and there was a fetid discharge. Profiting by the experience gained in the first case, the uterus was curetted and a considerable amount of decidua removed, and an intra-uterine douche given. In this case the womb almost at once contracted and the discharge ceased; but the patient had, unfortunately, an exacerbation of tubercular trouble in one lung, which kept the temperature high for some days.

In the third case, also a primipara, after an instrumental labor and an apparently normal lying-in, the temperature rose on the twelfth day to 99.8°, and on the day following to 100°. At the same time a fetid, muco-purulent discharge made its appearance. In this case a very large quantity of decidual membrane was removed, and the scraping was repeated on the following day, whereupon the temperature fell to normal and the discharge ceased.

The fourth case was a primipara, who on the sixth day, after an easy labor, had a temperature of 100°, although previously there had been no fever. The uterus here was very large, the os quite patulous, but in this case there was not much discharge. The same treatment was employed that had proved successful in the other cases, with the result of reducing the temperature within twenty-four hours to normal, where it remained.

Now, this experience is entirely too limited to enable one to come to a definite conclusion as to the cause of late infection in the puerperal state; but these cases suggested to my mind the possibility at least that the retention and subsequent decomposition of shreds of membrane or fragments of placenta will be found to be the most frequent cause of fever late in the puerperal state, and that, if not interfered with, this condition may lead to septicæmia and pyæmia. Other causes of fever late in the puerperal state are of course well known. Partially-healed wounds of the cervix, vagina, and perineum may be torn apart, and the fresh wounds thus produced may give entrance to the germs of septicæmia. Exposure to an atmosphere impregnated with emanations from sewers or water-closets from bad sanitation may give rise to febrile diseases at any time during the puerperium, as proved in the cases related by Dr. Playfair in a recent English journal. There is a possibility that the pyogenic micro-organisms which may carry on their work in the uterine cavity without very serious consequences to the patient may in the tubes manufacture their product, pus, in such quantities that it cannot be drained off, thus producing an abscess that may possibly open into the peritoneal cavity. There is a still more remote possibility that a pyosalpinx may be developed late in the puerperium by other pathogenic micro-organisms, by those of gonorrhœa, of tuberculosis, or even those of actino-mycosis. Finally, any of the febrile diseases that may attack a woman at any time may fasten themselves upon her during the lying-in period; but, as I have already said, it seems to me that the most common cause of late infection in the puerperal state is the decomposition of retained membrane or fragments of placenta, and that therefore the curette and the intra-uterine douche might be employed as a routine treatment in all cases where there occurs late in the puerperium fever associated with a large uterus, a patulous os, and a foul-smelling discharge. This treatment can do no harm, but may effect much good. My own experience in this direction is, however, limited, and upon this point I would like to have the opinion of the Society, whose experience, collectively and individually, must be greater than my own.

THE ANTISEPTIC PAD.

Dr. HIRST exhibited the antiseptic pad used by Richardson, of Boston, and Garrigues, of New York, to prevent the entrance of pathogenic germs to the vagina after labor.

Dr. PARVIN declared that he was not impressed with the necessity for the antiseptic pad, believing that as good results could be had from antiseptic napkins. The oiled silk or muslin used in making it, it seemed to him, might hinder the ready escape of the lochia. After labor, the vagina is practically a closed canal, open only for the egress of uterine discharge, and disease-germs cannot enter unless that canal be opened by some manipulation of the nurse or the physician, as in giving a vaginal injection or in making an examination. It seemed to him needless to close the vulva completely, and it also seemed possible that closure might hinder the escape of the lochia. But, be this as it may, if the vulva is carefully washed twice a day with an antiseptic solution, and if napkins that have been wrung out of a one-to-two-thousand corrosive-sublimate solution are applied over it, changing them more or less frequently, according to the amount of the flow, he thinks as good results can be had as by using the antiseptic pad. Moreover, it seemed to him doubtful whether antiseptic pads, though they have proved very useful in maternities, will be readily accepted in private practice, especially in the country.

In regard to the results in hospital practice from the use of antiseptics, he has no doubt of their value and should insist upon their employment. So, too, in private practice he has used them for some years; but it is only comparatively recently that he has learned how they should be used.

Dr. Parvin objects to the glass tubes for intra-uterine injections. Take, for example, Chamberlain's, and especially that of the late Albert H. Smith, and they will be found too large for use in some cases where injections are required. Then, too, the liability of glass to break is to him a conclusive argument against the introduction of an instrument made of this material into the uterus or into the vagina. The best instrument he believes is Bozeman's catheter. Formerly it was his custom to wait in cases of septic infection until the flow was offensive, and then at first to endeavor to correct the condition by vaginal, before resorting to uterine, injections. He now knows that is wrong, for the patient may perish or have a protracted illness and then make but partial recovery without the lochia at any time having an offensive odor. Within a year he has seen in hospital practice and in consultation eight cases of septic infection where the happiest results were promptly had from antiseptic solutions injected into the uterus. Most, if not all, of these patients probably would have recovered without these injections; but their recovery, judging from similar cases previously observed by him, would have been slow, possibly imperfect, and after a more or less prolonged period of suffering upon their part and of anxiety on the part of the practitioner. We have in antiseptic uterine injections the essential and the almost invariably successful treatment of puerperal septicæmia, if this treatment be begun soon enough and properly carried out.

Dr. BARTON inquired if the antiseptic pad was applied dry or moist.

Dr. T. M. DRYSDALE, while conceding the importance of antiseptic precautions in hospital, thought the advantage of these measures in private practice more difficult to prove. Until he relinquished obstetric practice in 1874 he had met with but five cases of puerperal fever in over two thousand deliveries, and in none of these women were any antiseptic precautions used other than cleanliness, as they were not then known.

Dr. LONGAKER believes with Dr. Hirst in the great utility of intra-uterine post-partum medication. Dr. Hirst has neglected to notice an agent in which he (Dr. Longaker) has the greatest confidence: iodoform, as used by Ehrendorfer, of Vienna, in the form of one-hundred-grain pencils. One of these is introduced into the cavity of the womb after irrigation; it dissolves very slowly, and continues to medicate the entire utero-vaginal canal for forty-eight or seventy-two hours.

In removing shreds of membrane after labor at term or after an incomplete abortion, he uses the finger, and prefers it to any form of curette he has used. Theoretically he would prefer a glass tube for intra-uterine irrigation, chiefly for the reason that it is more easily cleansed and kept clean. Hitherto he has always used the Bozeman cannula, the only objection to which is the difficulty of cleansing, and hence a possible danger of carrying sepsis directly from one case to another.

Dr. BAER emphatically endorses what has been said in favor of Bozeman's tube for intra-uterine irrigation and against the glass tube. The return-current is sure, and the small size of the instrument as compared with that of the glass tube renders its introduction easy and safe.

Regarding the pad exhibited by Dr. Hirst, if he believed the theory that the atmosphere is constantly impregnated with germs which poison whenever they come in contact with open vessels, he would certainly advocate the use of an impervious covering for the vaginal orifice. For the theory teaches that where there is no contact with the air there can be no sepsis. But he does not believe this fully. Therefore he thinks it safer to place the napkin under, and not over, the vulva, so as to permit as perfect drainage as possible, thereby giving free exit to the lochia by making of the vagina a drainage-tube,—its natural function after parturition.

Dr. HIRST remarked that the pads were used dry by Dr. Richardson and moist by Dr. Garrigues.

(To be continued.)

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

STATED MEETING, MARCH 28, 1887.

The President, LAURENCE JOHNSON, M.D., in the chair.

REMOVAL OF SOLID UTERINE AND OVARIAN TUMORS BY LAPAROTOMY, WITH CASES.

DR. MATTHEW D. MANN, of Buffalo, read the paper by invitation. He said the cases were not selected ones, but constituted his whole experience with such tumors. Three were cases of solid tumors of the ovaries; four were pedunculated fibroids of the uterus; two were fibroid enlargements of the uterus, requiring removal of the whole organ; the body of the uterus was removed also in another of the cases. More interest was attached to some than to others. Case III. was one of round, solid sarcoma of the left ovary, soft and friable. Had he recognized during the operation the ovarian rather than the uterine character of the tumor, he probably would have tied and dropped the pedicle. As it was, the clamp was applied, and after the clamp was taken off, and there seemed to be no strain upon the attachments, the bowels were moved, and this was followed by rise of temperature and pulse. Trouble with the pedicle was suspected, and it was found that the remains of the sloughing pedicle were attached to the broad ligament, while the fundus uteri was still attached to the lower edge of the incision. It was necessary to tear this loose. Hemorrhage occurring from the fundus, supravaginal hysterectomy had to be performed. The patient died of septicæmia the third day after this operation. Of the ovarian cases the first was an adeno-cystoma, the second a fibroma, and the third a sarcoma.

Dr. Mann saw the fourth patient first in 1882, and again in 1884. The diagnosis of either a solid ovarian tumor or a uterine fibroid was made. At the operation the tumor had the appearance of neither a fibroid nor a cyst. The pedicle was very short, thick, and vascular. A clamp was employed, and the pedicle was treated by the external method. A rent of the rectum took place during the operation from adhesions, and fluid entered the peritoneal cavity. This was due to retention of an enema which the nurse had given just before the operation. The tumor was a fibro-myoma. The patient made a good recovery.

Case V. was that of a woman, aged 33, the mother of six children. She had first noticed enlargement of the abdomen three years before the operation. Only latterly menstruation became too frequent, and she emaciated. The whole abdominal cavity up to the ribs was found filled with a tumor. There was a sensation as of ballottement. The tumor was found to be nearly solid, attached to the fundus of the uterus. It had a small pedicle. The tumor was divided before removing it. He thought of treating the pedicle by the external method, but unfortunately he changed his mind, tied it, cauterized its surface, and dropped it. The tumor was a soft myoma. In the evening the patient was about to go into collapse, and on reopening the abdomen the silk ligature was found to have slipped off entirely, and the patient was dying from hemorrhage. A clamp was now applied, and the patient was finally discharged cured. The principal point of interest in this case was reopening the abdomen for hemorrhage. He was sure that cases had been left to die where reopening of the abdomen and securing a bleeding point would have saved them. In this case the kidneys during the state approaching collapse failed to act properly, and the beneficial effect of an injection of hot water into the rectum, where it was retained, was manifest.

Case VI. was one of large uterine fibroid, involving the whole body of the uterus, producing great suffering. Supravaginal hysterectomy was performed; the clamp was applied. The patient made a good recovery from the operation and from the symptoms which had rendered life a burden.

Case VII. was one of myomatous enlargement of the body of the uterus, weighing about five pounds. The patient made a good recovery.

Case VIII. was one of fibro-cyst of the body of the uterus, from which nearly two quarts of pus were evacuated. The peritoneal cavity was thoroughly cleansed before closing the wound. The clamp was removed from the stump on the tenth day. The patient made a good recovery. A curious fact in the case was that the woman had become pregnant, and was delivered somewhat prematurely only a short time before the operation. Considering the condition of the uterus, it seemed strange that she should have become pregnant at all.

Dr. Mann said, in his concluding remarks, that the general profession labored under the belief that solid tumors of the uterus and ovary were beyond surgical reach, unless in the former they presented at the os. It seemed to him, however, that the removal of these tumors was no more dangerous than the removal of cysts, and the results of other operators did not differ much from his. The diagnosis was more difficult. But exploratory incision in many cases was less dangerous than leaving the case alone. As to the diagnosis of adhesions, length of pedicle, and attachments to other organs, he did not believe that any physician could do more than guess until after the abdomen was opened. He quoted approvingly the indications for the operation summarized by Keith, and said that all of his cases might have fallen under one of those classes except one, and for that one he thought another class might justly be made,—namely, that fibroid tumors, no matter what their size, which, by their presence

causing pain and suffering, were wearing out the patient, should be removed.

He would add another class of cases calling for supravaginal hysterectomy,—namely, sloughing intra-uterine fibroids which had already given rise to septicæmia, and the enucleation of which would only add to the danger by affording a new avenue of absorption. In only one of his cases could removal of the uterine appendages instead of removal of the uterus have been seriously considered, and in this case it was a question whether the operation would have had any effect upon the tumor. He could not but consider that some share of the success of his operations was due to the use of Wilson's clamp. It was needless to say that the strictest antisepsis was observed, and he placed the nail-brush and soap among the first on the list of antiseptics.

He suggested that the discussion be limited to the advisability of reopening the abdomen for hemorrhage and pelvic infection, removal of the uterus for myofibromata, and the treatment of the pedicle in supravaginal hysterectomy and myotomy.

DISCUSSION.

Dr. C. C. Lee was asked to open the discussion, and said he agreed in the main points made by the author of the paper. He did not quite agree with him as to the indications for the removal—either by hysterectomy or by other methods of laparotomy—of uterine fibromata in as wide a latitude as he had described. He believed that in all cases of solid growths of the uterus, where there was a chance of arresting nutrition of those growths by removal of the uterine appendages in young women, that method should be thoroughly considered before removing the tumor or uterus itself, and for this reason, that there might be a superitoneal fibroid in addition to the one removed, or others might develop subsequently. Dr. Lee had never had occasion to regret reopening the abdomen for hemorrhage.

Dr. James B. Hunter said with regard to the treatment of the pedicle of solid tumors that he was strongly in favor of the plan advocated by Dr. Mann,—viz., the external. He preferred the elastic ligature. Dr. Mann had been fortunate in seeing so many solid tumors. Dr. Hunter had diagnosticated and removed a solid tumor of the ovary within a year, the patient making a good recovery. He thought Dr. Mann should not remove the clamp so soon, at least in some of the cases.

Dr. W. Gill Wylie thought there could be no question of the propriety of reopening the abdominal cavity in suspected hemorrhage, and he suggested that when hemorrhage was feared a drainage-tube be introduced and carefully watched. He had resorted to this precaution in one case, but the assistant did not examine it often enough, and before the hemorrhage was discovered the patient was nearly in collapse. But the vein was tied and the patient recovered. He thought, with Dr. Mann, that it was risky to tie the pedicle of a muscular tumor. As to the indications for removal of the solid tumor, definite rules could not be made. For instance, in one case he found salpingitis complicating the fibroid of the uterus, and it would be difficult to say which condition was the chief cause of the woman's sufferings, and which should be removed. He would not hesitate to operate for a solid tumor any longer than to operate for a cyst, if the symptoms demanded it. He preferred the serre-nœud to the elastic ligature and other measures. Instead of loosening it the eighth or ninth day, he tightened it until it had gradually cut off the pedicle.

Dr. P. F. Mundé had operated in only two cases of solid tumor of the uterus,—one being a fibroid, weighing seventeen pounds, the other a myoma. In the first case the operation was performed because the patient had become addicted to opium for the relief of pain. The pedicle dropped off on the sixteenth day. In the second case separation of the adhesions led to rupture of the mesentery and intestine. Secondary hemorrhage took place twenty-four or thirty-six hours after the operation. The abdomen was reopened and the hemorrhage arrested, but the patient died of exhaustion in spite of transfusion of a saline solution.

As to diagnosis in case of myoma, it was not easy, but it could be distinguished from ovarian cyst by the thick abdominal walls; in cyst of the ovary of rapid development the walls were thin. We need not be in haste to operate for myomata of the uterus. Dr. Sims recommended an operation in one case some years ago, but the patient refused, and was to-day in the lecture-field. He had met with several cases of solid ovarian tumors, but had not operated.

Dr. Liel remarked that Dr. Sims had operated upon two cases of solid ovarian tumors within the past year. In one the tumor weighed about ten pounds, in the other about two pounds. The patients recovered.

Dr. Mann said that in removing the clamp on the eighth or ninth day he substituted for it an elastic ligature to cut it off. He doubted whether Dr. Mundé's suggestion as to differential diagnosis would hold.

NEW YORK ACADEMY OF MEDICINE.

A STATED meeting of the Academy was held April 7, 1887, the President, A. Jacobi, M.D., in the chair.

The Council recommended that a certain member be notified of the disapproval of the Academy of his action in endorsing a proprietary article. The report was adopted.

A memoir of the late Dr. H. W. Dudley,

by Dr. A. J. C. Skene, was read, in the absence of the author, by Dr. Thallon.

ON THE PROPER SELECTION OF ETHER OR CHLOROFORM AS AN ANÆSTHETIC.

While waiting for Dr. Gerster, the author of the paper, who was unavoidably detained, a letter was read from Dr. Herman Knapp, giving his experience with chloroform and ether:

"From 1860 to 1874 I used chloroform in over three thousand cases. There was no fatal result, but many unpleasant, and a certain number of critical, cases. About once a month I had to resort to artificial respiration and other means of resuscitation. Having seen fatal cases in Berlin and Vienna, I was in constant dread. From 1874 to this date I have used ether in all cases of anæsthesia, in children as well as in adults. No general complaint has been considered a contra-indication. I have administered ether according to the so-called choking plan, yet admitting so much air at the beginning as to let the patient get over the impression of asphyxia. A great many of the operations which I performed could be finished during the period of primary anæsthesia. Others lasted over hours, during which time the narcosis was kept up uninterruptedly. In several hundred cases of consecutive ether-narcosis I have taken notes of the time required to bring about anæsthesia: the average length of time was one minute and thirty-seven seconds. There were no fatal cases, and only a very few in which I had to interrupt temporarily the narcosis; there were none in which it had to be relinquished, as far as I can recollect. The secondary effect was no more unpleasant than from chloroform. I use ether as a universal anæsthetic, considering it safer than chloroform, just as manageable, if not more so."

Dr. A. G. GERSTER, having arrived, proceeded to read his paper. He said both chloroform and ether are dangerous anæsthetics. Chloroform produces very marked depression of the vaso-motor functions. This depression occurs only occasionally in ether-anæsthesia. The practical significance of this fact is that chloroform is the more powerful agent, and its administration requires much greater caution. But this is not sufficient ground for its unqualified condemnation. Consciousness being restored, there is no secondary danger from chloroform. Ether, on the other hand, has not caused as often immediate death on the operating-table, but the dangers from ether do not cease the moment the patient comes from under its influence. Numerous cases of nephritis and pneumonia have followed its use. He would show where chloroform was the more dangerous anæsthetic and should not be used; on the other hand, also where ether was the more dangerous and should not be used. There was too much one-sidedness in favor of ether among physicians of the Eastern cities.

In giving ether, he used Ormsby's inhaler as the best; less ether was required, and consequently it took a shorter time for the patient to regain consciousness. Ether is contra-indicated in renal disease. Its dangers here had been pointed out by Dr. Emmet. That chloroform is much safer in Bright's disease than ether had been abundantly shown. It had been employed for hours in such cases without any tendency to uræmic eclampsia. Fatal cases were cited in which ether had caused death subsequent to its administration by superadding an acute attack to pre-existing nephritis.

Ether was also contra-indicated in bronchitis, and it not unfrequently led to pneumonia in such patients. Three cases were related in which pneumonia followed the use of ether, death resulting. Three other cases had occurred in another hospital during 1886, reported to him by the house-physician. Five cases of serious bronchitis developed after the use of ether in the German Hospital during 1886. After attention had been called to the subject, doubtless other cases would be reported.

In certain classes of cases ether acted badly, as in herniotomy, operations involving the peritoneum, removal of deep-seated tumors in the vicinity of large vessels. Out of one hundred and twenty-five cases in which ether was administered at the German Hospital during 1886, in eleven it acted badly. In such cases chloroform, being substituted, produced complete anæsthesia. Persons addicted to alcohol, perhaps only moderately, were likely to take ether badly.

There was but one contra-indication to the use of chloroform,—namely, a weak heart from any cause whatever. This might occur from fear of the operation or nervous depression. Valvular disease did not necessarily signify a weak heart and contra-indicate the employment of chloroform. Ether was also more dangerous in these cases, but less so than chloroform.

Dr. R. F. WEIR opened the discussion. He said there has been a growing feeling among us that ether is not so safe an anæsthetic as we have for some years believed. Dr. Gerster had cited some of the reasons for this feeling, notably the danger in kidney-disease; "but I think he has stated too positively that where we find albumen, casts, etc., in the urine, ether should not be given. I have frequently given ether in such cases, and latterly, since recognizing the risk, I have administered the anæsthetic much more cautiously, but so far I have not had any reason to complain of the action of the anæsthetic. Dr. Gerster is right in stating that ether is used recklessly to a great extent.

"In certain affections of the larynx ether is contra-indicated; but I would not say that

ether should not be used in kidney-disease: I would say that it should be used cautiously.

"As regards the occurrence of pneumonia, of course ether does bring cold vapor to the lungs. But I noticed that after the introduction of the spray we had pneumonia oftener than formerly. Now we have another cause of pneumonia in our wet carbolized gauze laid so freely upon the patient. The pneumonias which I have seen could be traced to incautious exposure of the patient."

Dr. Weir stated some statistics relative to the number of deaths from ether and chloroform throughout the world, and, referring to the experience at the New York Hospital, he could cite only four deaths occurring during the operation from ether. One other case had occurred at the House of Relief. Although in some cases ether was taken badly, yet at the Hospital they had been able always to continue the operation.

Dr. L. A. SAYRE said he was so thoroughly convinced of the correctness of his own views regarding the relative value of ether and chloroform that he had continued the use of chloroform notwithstanding the general opposition manifested towards it. He prefers chloroform to ether because it does not produce spasmodic muscular contraction; it is more agreeable to the patient; it is more speedy in its effect; it is not followed by bad after-effects, such as vomiting, Bright's disease, pneumonia, etc. The use of chloroform or ether without measure, freely mixing them with the air, which was their antidote, was wrong. Chloroform and ether are both powerful agents; each has caused many deaths. Therefore they should be used with the same care and skill in measuring the dose and guarding against accidents as in the employment of any other potent drug.

Dr. Sayre showed the inhaler which he had used for years, by which the amount of chloroform could be measured perfectly, and the air to any degree excluded. Administered in this way, twenty or thirty drops of chloroform would almost invariably produce anæsthesia by a few inhalations; and if from any cause the heart should cease to act, it could be restored by a few efforts at artificial respiration. If, however, the chloroform were given mixed freely with air, as was so commonly done, a larger quantity would be required, and restoration of the heart's action would be impossible.

Dr. W. GILL WYLIE said that during the last two months he had lost two patients from the influence of ether, whereas prior to that he could not recall a single instance. He thought Dr. Gerster spoke truly when he said that ether was administered recklessly in New York. One of his patients died of Bright's disease following the use of the ether, while the second died within an hour after finishing a herniotomy, probably from suffocation. She weighed as much as two hundred and fifty pounds. Very fat patients were more likely to die of suffocation during the use of the anæsthetic. He recalled a third case of death from ether during the operation, occurring within a block of where his own patient died. He would, as a rule, give ether in preference to chloroform, especially in general surgical operations; but in the lying-in room and in children he would give chloroform. But there were also cases where the kidneys or lungs were diseased in which chloroform should be employed.

Dr. W. A. WYETH would use chloroform when patients were under six years of age. Experience seemed to show that it was perfectly safe and to be preferred to ether in childbirth. A third indication for chloroform was the fact that the patient had previously taken ether badly. It might also be used when ether could not be obtained. He would use ether although there was nephritis, but cautiously, and if dangerous symptoms arose he would substitute chloroform. He had never seen, as far as he could remember, any accident from ether; certainly no death. He had not met with the class of cases referred to by Dr. Gerster, in which the patient could not be anæsthetized by ether.

Dr. ABBE had seen only one death from ether: it occurred in the practice of the late Dr. Little, the operation being for tetanus. So far as pneumonia and nephritis following ether-administration were concerned, both were under our control. He thought pneumonia was more likely to be due to draughts and other exposure after or during the operation. Four cases of acute nephritis after the use of ether had come under his observation during the past year.

Dr. P. F. MUNDÉ had formerly used chloroform a great deal, and, while he had seen no deaths from it, he had seen patients restored with difficulty, and he was in great fear of it. He had during later years employed ether almost exclusively. But both were powerful drugs, and he felt more anxiety with regard to the anæsthetic than with regard to the operation. Ether, however, was the safer. He preferred Clover's inhaler. In some cases he had failed to get the patient satisfactorily under the ether, and had substituted chloroform, rendering the patient completely anæsthetic. In short operations he preferred chloroform. In obstetrics he preferred chloroform. In long operations he preferred ether, given by Clover's inhaler.

Dr. R. W. AMIDON, referring to the collection of mucus in the bronchi during ether-administration, recommended as a preventive the use of atropine or a preparation of belladonna prior to the administration of the ether.

Dr. THALLON thought kidney-disease should not contra-indicate the use of ether, but it should make us cautious. The best inhaler was that employed by dentists in giving nitrous oxide.

Dr. GERSTER closed the discussion. Speaking of the cause of pneumonia, he was of the opinion that the secretions of the mucous membranes were changed by the ether in inhalation, and these, entering the air-passages, set up inflammation. Statistics, as they had been collected, were worth nothing in deciding whether ether or chloroform was the safer anæsthetic. He knew of five deaths from ether in one hospital which had never been reported. Again, how often had ether caused death from nephritis or pneumonia hours or days after the operation, the cause of the pneumonia or kidney-disease never being recorded!

REVIEWS AND BOOK NOTICES.

THE PRACTITIONER'S HAND-BOOK OF TREATMENT; OR, THE PRINCIPLES OF THERAPEUTICS. By J. MILNER FOTHERGILL, M.D. Third American from the Third English Edition. Lea Brothers & Co., Philadelphia, 1887. Pp. 660.

The lessons in rational medicine which Dr. Fothergill essayed to teach in this work have not fallen upon unappreciative ears, and the favor accorded to former editions has led to increase in size by the addition of important chapters on "The Dietary in Acute Disease and Malassimilation," and on "The Management of Convalescence."

This work on the principles of therapeutics has been previously favorably noticed in these pages, and we can only repeat our former expression of commendation, and again urge it upon the attention of our readers.

HYSTÉRIE ET TRAUMATISME: PARALYSIES, CONTRACTURES, ARTHROLOGIES, HYSTÉRO-TRAUMATIQUES. Par le Dr. PAUL BERBEZ. Paris, 1887.

This is an interesting monograph of some one hundred and twenty-five pages, discussing the history, etiology, symptoms, diagnosis, pathogeny, prognosis, and treatment, as well as full clinical reports of twenty-six cases, of hysteria following injury of a more or less simple character. The author's style is clear, concise, and readable. His assertions are based upon the study of a hundred cases, selected, with the assistance of Professor Charcot, from the wards of La Salpêtrière. In his own words, he proposes to consider "hysteria from the surgical stand-point." He maintains that the various paralyses, contractures, anæsthesias, pains in the joints, etc., which frequently follow injuries of a slight character, such as luxations, contusions, and bruises, are chiefly hysterical, and must be treated accordingly.

The chapter upon the pathogeny of the disease, though of a nature highly theoretical, bespeaks an originality and force of reasoning which will always awaken interest and command respect. We could have wished that the chapter upon the diagnosis had been made somewhat more exhaustive, since that is the feature of the disease about which we need at present the most information. In his treatment the author presents nothing new, but he insists forcibly upon the moral and physical care of the case.

Although the reader may differ from some of the conclusions, he must nevertheless admit their practical bearing for surgeons, while their theoretical considerations for psychologists possess interest and value, and mark this as a valuable contribution to the study of this confessedly obscure subject. L. H. M.

THE PHYSICIAN'S DOSE AND SYMPTOM BOOK: Containing the Doses and Uses of all the Principal Articles of the Materia Medica and Officinal Preparations in Alphabetical Order. By JOSEPH H. WYTHE, M.D. Seventeenth Edition. Completely rewritten and enlarged. P. Blakiston, Son & Co., Philadelphia, 1887. 12mo, pp. 226.

This convenient little volume is very useful for reference as to doses of the various preparations of drugs and their uses. It also contains valuable lists of incompatibles, of antidotes to poisons, and of symptoms and treatment of the principal diseases.

MISCELLANY.

JUDGE C. C. FULLER, of Michigan, decided, when a physician refused to testify on the ground that the evidence would be expert testimony, "After many years' study and observation, I decide that a physician's knowledge is his stock in trade, his capital, and we have no more right to take it without extra compensation than we have to take provisions from a grocery, without pay, to feed the jury. The court rules that the witness is not *compelled* to testify."

THE next meeting of the Medical Editors' Association will be held in Chicago on Monday evening preceding the meeting of the American Medical Association. The President, Dr. Shoemaker, will deliver an address: "Some of the Present Abuses of Medical Literature." It is desirable that all medical editors who can shall attend, as the organization is a permanent one and largely social. Dr. T. L. Gray, of Chicago, is Chairman of the Committee of Arrangements.

Members of the press who expect to be present should send their names as early as possible to the Secretary, Dr. William Porter, 3137 Lucas Avenue, St. Louis. Exchanges please copy.

NOTES AND QUERIES.

OBITUARY.

ELLIOTT RICHARDSON, M D., Lecturer on Operative Obstetrics in the University of Pennsylvania, Obstetrician to the Philadelphia Hospital, and Gynæcologist to the Pennsylvania Hospital, died on the 9th instant of typhoid fever.

Dr. Richardson came of an old Quaker family, and was educated at the Friends' School in this city, afterwards graduating from the Medical Department of the University of Pennsylvania in 1867. As a student he was faithful and conscientious, and as resident physician in Wills, the Philadelphia, and the Pennsylvania Hospitals gained the regard and respect of his contemporaries and of the older men under whom he served, many of whom were his friends in after-life.

Commencing practice in 1870, he soon began to devote himself especially to the study of obstetrics and gynæcology, and spent years of laborious practice among the poor and in dispensaries until he obtained a thorough knowledge of these subjects. He located at first in Spruce Street, near Seventh, but within the last ten years moved westward to the more fashionable part of the city, where he was rapidly building up a large practice among the best class of his fellow-townsmen, when death overtook him and cut short his career just as he was beginning to reap the fruits of nearly twenty years' study and unrequited labor.

Dr. Richardson was naturally of a retiring disposition, and was intimately known to but few, although his occupation brought him outwardly before many. He was above all things a practitioner. He showed at his best beside the bedside of the sick and in the lying-in chamber. His readiness for every call of charity or suffering, his tender sympathy for pain and distress, no less than his mastery of every diagnostic and therapeutic means, marked the ideal minister to the sick, while his punctilious sense of honor and of professional courtesy was such as commanded the respect even of those whose own course was actuated by a less lofty ideal.

As a teacher of obstetrics and gynæcology Dr. Richardson was lucid and satisfactory in explanation and skilful in demonstration, while as a general lecturer on didactic subjects he was less impressive. His chief success, in his own estimation, was in the case of the well-known Porro-Müller operation which he performed a few years ago, and which was and we believe remains the only successful operation of the kind as yet performed in this country.

Personally, Dr. Richardson was to his intimate friends a charming companion. An unbroken friendship of twenty-one years enables the writer to speak on this point with knowledge. His acquaintance with the best classical English literature was extensive, and was used to enliven his conversation in a way that only his chosen friends had the opportunity to enjoy.

A man of high moral character and deep religious feeling, he rarely expressed himself freely, but in every action of his life the moving springs of his conduct could be seen. Few men of his age could less easily be spared from the ranks of the medical profession in this city, for few so well upheld the ethical and professional standard which in this mercenary age is with so much difficulty maintained. A. V. H.

A PRIZE ESSAY ON HAY-FEVER.

At its last meeting, September, 1886, at Bethlehem, New Hampshire, the United States Hay-Fever Association decided to offer a prize for the best essay from a competent source, preferably a physician, on some question relating to *Catarrhus æstivus*, or hay-fever.

In order to carry out the above, the following is announced officially:

1. Subject of the Essay, Hay-Fever. (*a*) Its Pathology. (*b*) The predisposing and the aggravating causes. (*c*) Advice to the sufferer.

2. The essay not to exceed *four thousand words*, and to be as practical and non-technical as possible.

3. The manuscripts to be received at the office of Samuel Lockwood, Freehold, New Jersey, not later than April 30, 1887.

4. Each manuscript to have a motto under the title, and to be accompanied with a sealed letter containing said motto, also the name and address of the author. These letters not to be opened until after the award is decided.

5. The prize to be $25. The accepted essay to be published immediately in the Association's annual report, one hundred copies to be given the author.

6. The Committee of Award: Samuel Lockwood, Chairman of Committee on Scientific Facts; Frank B. Fay, President U. S. H. F. A.; Charles C. Dawson, Secretary U. S. H. F. A.

SAMUEL LOCKWOOD,
Chairman of Committee on Scientific Facts.
FREEHOLD, N.J., January 15, 1887.

OFFICIAL LIST

OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U.S. ARMY FROM APRIL 24, 1887, *TO MAY* 7, 1887.

MAJOR BLENCOWE E. FRYER, SURGEON.—Ordered for examination by Army Retiring Board at San Francisco, California. S. O. 101, A. G. O., May 2, 1887.

MAJOR GEORGE M. STERNBERG, SURGEON.—Assigned by the President to the special duty, under the Treasury Department, of "investigating the merits of the method practised in Mexico and Brazil for preventing yellow fever by inoculation." Relieved from duty as attending surgeon and examiner of recruits in Baltimore, Maryland. S. O. 101, A. G. O., May 2, 1887.

MAJOR JOHN S. BILLINGS, SURGEON.—Granted leave of absence for ten days, to take effect May 3, 1887. S. O. 98, A. G. O., April 28, 1887.

MAJOR J. V. MIDDLETON, SURGEON; MAJOR J. C. G. HAPPENSETT, SURGEON; CAPTAIN F. C. AINSWORTH, ASSISTANT-SURGEON.—Appointed to assemble at the United States Military Academy, West Point, New York, on June 1, to examine into the physical qualifications of the members of the graduating class and of the candidates for admission to the Academy. S. O. 102, A. G. O., May 3, 1887.

CAPTAIN LEONARD Y. LORING, ASSISTANT-SURGEON.—Sick-leave of absence still further extended six months on surgeon's certificate of disability. S. O. 103, A. G. O., May 4, 1887.

CAPTAIN VICTOR BIART, ASSISTANT-SURGEON.—Sick-leave still further extended one year on surgeon's certificate of disability. S. O. 99, A. G. O., April 29, 1887.

FIRST-LIEUTENANT CHARLES B. EWING, ASSISTANT-SURGEON.—Ordered from Fort Leavenworth, Kansas, to Fort Lewis, Colorado, for temporary duty. S. O. 100, A. G. O., April 30, 1887.

FIRST-LIEUTENANT CHARLES E. WOODRUFF, ASSISTANT-SURGEON (recently appointed).—Ordered for duty at Fort Wayne, Michigan. S. O. 96, A. G. O., April 26, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U.S. NAVY FOR THE TWO WEEKS ENDING MAY 7, 1887.

ASSISTANT-SURGEON L. W. ATLEE.—Ordered to the Receiving-Ship "Vermont."

PASSED ASSISTANT-SURGEON CLEMENT BIDDLE.—Detached from the Naval Academy and to Marine Rendezvous, Philadelphia, Pennsylvania.

PASSED ASSISTANT-SURGEON RICHARD ASHBRIDGE.—Ordered to the Naval Academy.

MEDICAL INSPECTOR A. HUDSON.—Ordered to the U.S.S. "Trenton."

PASSED ASSISTANT-SURGEON C. T. HIBBETT.—Ordered to the U.S.S. "Trenton."

ASSISTANT-SURGEON CORBIN J. DECKER.—Detached from the Receiving-Ship "St. Louis" and to the U.S.S. "Trenton."

ASSISTANT-SURGEON JOSEPH SHAFER.—Detached from the "Minnesota" and to the "Ossipee."

SURGEON W. J. SIMON.—Ordered to the U.S. Steamer "Boston."

ASSISTANT-SURGEON C. P. HENRY.—Detached from hospital, Philadelphia, and to the "Boston."

ASSISTANT-SURGEON VICTOR C. B. MEANS.—Detached from hospital, Mare Island, and to the hospital, New York.

PASSED ASSISTANT-SURGEON MANLY H. SIMONS.—Detached from Naval Academy and to the "Constellation."

PASSED ASSISTANT-SURGEON OLIVER DIEHL.—Detached from hospital, New York, and to the hospital at Philadelphia.

PHILADELPHIA, MAY 28, 1887.

ORIGINAL LECTURES.

CLINICAL LECTURE

ON CASES ILLUSTRATING THE USE OF ADONIDINE IN DILATED HEART, AND THE TREATMENT OF CEREBRAL APOPLEXY.

BY J. M. DA COSTA, M.D., LL.D.,

Professor of Practice of Medicine and of Clinical Medicine in the Jefferson Medical College; One of the Attending Physicians to the Pennsylvania Hospital, etc.

GENTLEMEN,—I shall bring before you cases, this morning, which will serve to illustrate some therapeutical points which you may find to have practical value. The first one is the case of A. B., a man, 23 years of age, in whose family history we can trace rheumatism, and whose occupation constantly exposes him to changes of weather: he is a teamster. Previous to his present malady he states that he enjoyed excellent health. He has never had rheumatism, and denies specific infection. There is no evidence of excesses in drink, he smokes moderately, and, in truth, his habits in every respect appear to be good. Up to the time of the onset of his present illness he does not recall the fact that he had been at all troubled with shortness of breath. About three months prior to his admission into the hospital, which was on the 29th of November, he noticed that he had diarrhœa and paroxysmal pains in the lower part of the stomach, and also pain in his chest, accompanied by difficulty in breathing. Indeed, this dyspnœa at once assumed serious proportions, and it has continued ever since,—according to the notes, at times more, at times less, severe; but there seems to be no time, either in the day or night, in which he did not suffer with shortness of breathing. About three weeks prior to entering the wards he also noticed palpitation of the heart, coming on irregularly, which increased his discomfort. He had no attacks of vomiting, and his digestion was good. He continued at his occupation until the middle of November, when he was obliged to give up heavy work, and confined himself to light labor about the stable. On the 20th of November his feet began to swell, and the swelling steadily increased; it was not accompanied by œdema in other portions of his body. Prior to admission there was another outbreak of diarrhœa, but it was unaccompanied by marked gastric symptoms.

His condition on the day of admission (November 29) was entered upon the notes as follows. "Face puffy, feet and legs greatly œdematous; his lips and nails cyanotic; his pulse weak and irregular. The urine was scanty, of specific gravity 1024, and contained a small proportion of albumen, but no tube-casts were detected." The axillary temperature was sub-normal: the record states that it was 98° on admission; for the next eleven days, as you see by the chart, it remains about 96°, occasionally rising to 97°. On December 11 it becomes normal, and remains subsequently at 98.4°.

Now, gentlemen, irrespective of what I have told you, we have here a note of a heart-examination made the day subsequent to admission which shows what is the source of this man's illness. "Heart's action is extremely irregular; percussion-dulness extends almost to the right edge of the sternum from a point outside the mammary line; the apex-impulse can be felt in two intercostal spaces, and in this region there is present a distinct presystolic murmur. The second sound of the heart is heard at the base, and is especially distinct at the left base."

The diagnosis was made of mitral organic lesion, with narrowing of the orifice, stenosis. At the same time the increased percussion-dulness and the extended impulse, the apex-beat being feeble as compared with the extent of the dulness, give us a further diagnosis of cardiac dilatation with slight hypertrophy. The pulse was feeble, irregular, and difficult to count, but was about eighty in the minute. This is the record of the heart-lesion. The lungs presented nothing of importance.

We placed the man upon digitalis, with, to a certain extent, good results. Under the infusion of digitalis this happened: the dropsy disappeared, and the breathing was somewhat relieved; the heart's action became more regular and increased in force, but not to the extent that we hoped. Indeed, the action of the digitalis seemed here to be chiefly diuretic, and expended on the dropsy: it was very slight upon the heart.

After waiting several days I concluded that a pure heart-tonic would be serviceable, and then gave him the new remedy, adonidine: one-tenth of a grain was given three times a day at first; subsequently it was given five or six times in the twenty-four hours. The effect of this upon the heart was strikingly good.

In the first place, from the dates I see clearly that the temperature rose coincidently with the administration of the adonidine; the low temperature, which had continued all the time he was taking digitalis, ceased when he began to take the new remedy. Secondly, this was attended with an increase in the strength and action of the heart, proving its influence as a cardiac tonic. In one respect adonidine was different in its action from digitalis: it had no diuretic action. The urine came down to a pint in twenty-four hours; and this made me, on the 24th, return to the digitalis (a dessertspoonful of the infusion four times a day); the urine at once increased, but the improvement in the heart remained stationary.

Having told you his clinical history, I will now examine him before you. With regard to his shortness of breath, this is vastly better. This was noticed at first under digitalis, but the greatest improvement occurred when he was taking adonidine. His face is somewhat suffused and the capillaries are enlarged, but not nearly to the extent that they were at first. The dulness on percussion in the cardiac region is large, the apex beats to the left of the nipple, and the impulse has more force than it had, but it is still more diffuse than it should be. There can be no doubt that the heart's impulse is stronger than it was. Auscultation reveals, just over the apex, a most marked presystolic murmur, passing over into the systole. In other words, there is narrowing or stenosis passing into insufficiency. With regard to the second sound, I find it accentuated, but the difference between the right and left base is not very marked, not enough, at least, to make it a point in the diagnosis. The murmur is also heard, though faintly, at the angle of the left scapula. There are no marked pulmonary signs.

This case is diagnostically clear enough. I did not purpose discussing the points of diagnosis with you; it is the therapeutic aspect of the case which is so striking, as it enables us to draw some comparison between digitalis and the new alkaloid, adonidine. I selected this agent because, while its powers as a heart-tonic are not inferior to digitalis, it is free from the disturbing action of the latter. There are so many claims made in favor of new drugs, and especially heart-tonics, that it makes one suspicious of them all; but having used adonidine for some time, I consider it a valuable addition to our therapeutics of heart-affections, and have not observed from it anything resembling the cumulative effect which at times, though rarely, follows the administration of digitalis. In this case the contractions of the heart, while they became more regular, were reduced to fifty-six per minute. He had slight vertigo and headache, which disappeared upon resuming the infusion of digitalis, while the adonidine was continued. This drug will never supersede digitalis in the treatment of cardiac dropsy, from its want of diuretic action, but in other cases this might prove a decided advantage. Without discussing the effects of the agent upon the cardiac dilatation and hypertrophy, and merely referring you to the relief from the dyspnœa and the increase in the strength of the pulse, I point out to you that all this was associated with a very considerable amount of cardiac dilatation or stretching, with very little hypertrophy. There is another patient in the ward with very decided hypertrophy in whom the adonidine produced disagreeable results: the heart's action became intensified, and attacks of palpitation came on upon slight exertion. I recall another case in private practice where the same result occurred: the heart was strengthened too much. This all shows that it is a decided heart-tonic, and also indicates its line of usefulness. In a given case of weak and disordered circulation, the nearer it approaches a condition of dilated heart the more benefit from the adonidine; the more it approximates hypertrophy and over-action of the heart, the more is this agent contra-indicated. In cases of weak digestion with weak heart, it is especially suitable.

CEREBRAL APOPLEXY — HEMIPLEGIA — PROMPT TREATMENT BY VENESECTION — RECOVERY.

In conclusion, I will ask your attention to a case which you have seen in its more acute stage. This was a case of apoplexy with left hemiplegia. The man has done

very well, but I thought that it might be of interest to you to observe the effects of treatment. When admitted, twenty ounces of blood were taken from his arm with evident benefit, and croton oil was given, which purged him freely. One drop of tincture of aconite was given every second hour at first; four days later he was given potassium iodide, a scruple four times daily.

You see that this man has recovered power to a very considerable degree, and the leg is regaining strength even more than the arm. Some facial paralysis remains. He has now reached the stage for local treatment, massage, friction, and stimulation of the muscles by the use of mild faradic currents.

It is always a nice question when to begin this local treatment after apoplexy. My rule is to begin rather late than early. I wait until voluntary power commences to return in the muscles. If it is begun too early we run the risk of increasing the brain-lesion. Later still, I usually give strychnine. I believe that harm is done by using either too early.

This patient has reached a stage in his history when the brain-malady is not active, and we will therefore use massage daily and electricity every second day.

There is still a trace of albumen in the urine. In every other respect he has strikingly improved. You remember that I told you, when he was the subject of discussion before, that the albumen in the urine had something to do with causing the hemiplegia: therefore its persistence now simply proves that the original view was correct.

ORIGINAL COMMUNICATIONS.

REPORT ON THE PROGRESS OF DERMATOLOGY.

BY ARTHUR VAN HARLINGEN, M.D.,

Professor of Dermatology in the Philadelphia Polyclinic.

(Continued from page 539.)

THE SYPHILODERMATA.

TWO papers have recently appeared upon hemorrhagic syphilis. In the first of these Horovitz (*Vierteljahresschr. f. Derm. u. Syph.*, Jahrg. xiii. S. 351) gives an account of two interesting cases observed in Auspitz's clinic. The first was a man, of 26, suffering from an early generalized syphiloderm of the papular variety, which was cured by mercuric inunction. He was then placed upon twenty-four grains of potassium iodide thrice daily, but within ten days an eruption of small red papules occurred upon the body and limbs which soon took on a hemorrhagic character. The potassium iodide was then suspended, but new lesions continued to come out for about twelve days.

Horovitz's second case was a young man, of 25, in the early stage of generalized syphilis, showing moist papules about the arms, etc., who also displayed a peculiar eruption chiefly upon the forehead, back, and extremities, excepting the hands and the feet. This eruption was composed of confluent lesions: in the centre of each a large flat papular lesion, and around this a hemorrhagic ring, the whole compound lesion in some places being as large as the palm of the hand. The patient was placed under observation without treatment, and the eruption gradually disappeared, being practically gone at the end of six weeks.

Horovitz theorizes at some length over these cases, but the first seems very much like an iodide-of-potassium eruption, while the last is worthy of attention whether the hemorrhage was due to syphilis or not.

Hartmann and Pignot (*Annales de Dermatologie et de Syphiligraphie*, 2me sér., t. viii. p. 1) put forth a paper on the same subject, but of a very different character, the whole matter being classified and treated under various heads, with illustrative cases. The authors conclude that in congenital syphilis there seems at times to be a true hemorrhagic diathesis. In acquired syphilis there is no proof of a diathetic influence producing hemorrhage from simple wounds. Even when the knife is used upon syphilitic lesions, serious hemorrhage is exceptional. Syphilitic ulcers do not bleed profusely, except where vessels may be laid open by the disease-process. Syphilis may, however, cause arteritis, and thus lead to softening of the walls of the blood-vessels, particularly those of the brain. Paroxysmal hæmoglobinuria is not unfrequently caused by syphilis, operating, as Murri thinks, both on the organs which form the globules and on the vaso-motor centres. Syphilis may give rise to cutaneous hemorrhages, (*a*) on the surface of pre-existing lesions, (*b*) by acting as a determinate cause of a purpura which shows itself in the secondary stage of the disease,

and with the usual symptoms of that affection.

Weyl, in his article on psoriasis in Ziemssen's Hand-Book, having asserted that syphilis has no influence upon psoriasis, Dorwig (*Vierteljahresschr. f. Derm. u. Syph.*, Bd. xiii. S. 149) asks the converse question, Has psoriasis any influence upon syphilis?—*i.e.*, as regards the development of the syphilodermata,—and believes himself in a position to answer the question in the affirmative as the result of his observation of a case of which he gives the notes. A young man came under his care suffering from an initial lesion of syphilis, who also displayed an extensive and well-marked eruption of psoriasis which he had had for eight years. When the generalized syphilitic eruption broke out, which took place with headache, fever, etc., about two weeks after he came under Weyl's observation, it was found that the syphilitic eruption had at many points supplanted the psoriatic lesions, the transformation taking place gradually and *in situ*.

Weyl contrasts the pathological anatomy of the psoriatic and syphilitic eruptions, and demonstrates how the peculiar enlargement and multiplication of the capillary loops in psoriasis favor the development of the syphilitic lesions. His views appear very plausible, and are worthy of further attention.

It is known that syphilis does not preclude the synchronous occurrence of the acute infectious diseases. These, however, suppress the appearance of syphilitic symptoms temporarily, but the latter return when the intercurrent acute infectious disease has run its course. An exception to this fact has, however, been asserted in the case of erysipelas, which is said to have a certain curative influence on syphilis.

Mauriac observed a number of cases of initial lesion and generalized symptoms yield to an attack of erysipelas, sometimes eventuating in a cure, but in cachectic cases unfortunately leading to a fatal termination. Deahna observed a case in which an attack of erysipelas removed the syphilitic symptoms, which returned in a milder form, to be entirely dissipated by a second attack. Other observers have noted similar cases, the erysipelas in some instances affecting only the syphilitic lesions lying in its path, in other instances affecting even distant lesions.

The question has arisen in connection with this subject, whether by weakening the intensity of erysipelas by appropriate cultures an efficient specific against syphilis would be obtained. Unfortunately for this theory, eruptions of lupus and non-syphilitic tumors have also disappeared during attacks of erysipelas, thus throwing doubt upon the specific effect of the erysipelas coccus upon the syphilitic element.

Moreover, occasionally the favorable effect of erysipelas upon such growths is offset by fatal results: *e.g.*, Jarnhe and Neisser inoculated a carcinomatous subject with erysipelas with a fatal result from the erysipelatous process itself.

Schuster gives three cases of simultaneously occurring syphilis and erysipelas which are quite interesting. One was that of a patient suffering from nasal syphilis, where erysipelas originated in a specific excoriation about the ala nasi, spread over the face and scalp, and ended fatally. The seeond was an old syphilitic patient, who had a similar excoriation about the ala nasi, and who while under treatment was attacked by very severe erysipelas starting from this point, which eventuated in recovery. Two years later, however, marked serpiginous syphilitic ulcers developed. The third case was a patient not suspected of syphilis, who had repeated mysterious attacks of facial erysipelas. The starting-point of these was discovered to be in certain old neglected or unseen syphilitic lesions of the nasal opening. These facts, Schuster thinks, prove erysipelas to differ in no way from the other acute infectious diseases in its influence upon syphilis.

Köbner (*Vierteljahresschr. f. Derm. u. Syph.*, Jahrg. xiii. S. 831) has something to say about the desirability of uniformity in recording cases of syphilis, and gives a scheme for setting down the history and various symptoms of cases of acquired syphilis and also the history and symptoms of cases of hereditary syphilis. The scheme might well be carried out with advantage, and deserves study by younger men because it shows the points of importance in the study of cases of syphilis.

The contributions to the study of syphilitic disease of the skin contained in our American special journal are not numerous. In fact, a single paper by Knoche on a case of "rupia syphilitica" confined almost exclusively to one side of the body,

the title of which explains its scope, is all that we have on the subject.

COMEDO.

Two articles on this affection have appeared this year, both in *Morrow's Journal*, and both by Dr. Ohmann-Dumesnil (*Jour. Cut. and Ven. Dis.*, February and July, 1886), who calls attention to what he calls double comedo, where pressure on the skin forces a plug of sebum discolored at each end out of either of two contiguous openings. The circumstance seems to be of little importance.

HERPES ZOSTER: ITS RELATIONS WITH H. FACIALIS AND H. GENITALIS.

Epstein, of Neisser's clinic in Breslau (*Vierteljahresschr. f. Derm. u. Syph.*, Jahrg. xiii. S. 777), says that the question of the identity of these various forms of herpes was raised by Bärensprung in his classical article on zoster years ago. Gerhardt supported this view, and suggested an examination into the relation between the facial herpes of acute febrile diseases and the rise in temperature. Just as there is usually a prodromal neuralgia in zoster, so in facial herpes an initial chill precedes the eruption by three days on an average. The initial chill seems to suggest the probable origin of the eruption; but to explain how the rise in temperature can exert a direct influence upon the minute twigs of the trigeminal, Gerhardt suggests that the nerve passes through a narrow bony canal along with a small artery, which is first narrowed and then enlarged by the febrile influence. The pressure of the nerve-trunk between this artery and the bony wall causes more or less irritation of the nerve-trunk.

In the case of herpes genitalis, Mauriac has been brought to the conclusion that this also is due to a nerve-lesion and is closely connected with herpes zoster. Epstein examines carefully into the *pros* and *cons* of the question, and analyzes carefully the views of prominent writers on the subject, finally leaning strongly to the conclusion that all the forms of herpes have a common pathological origin, however differing in their clinical appearance and course.

DYSIDROSIS.

George Thomas Jackson gives (*Jour. Cut. and Ven. Dis.*, January, 1886) a case, with chromo-lithograph, of this curious affection. The eruption affected the face, presenting the usual symptoms of large and small sago-grains scattered over the affected parts, and consisting of freely-distended vesicles with clear contents. The largest vesicles were about the size of a split French pea, the smaller ones were about the size of a pin's head. They were generally discrete, though here and there closely crowded together. When pinched, a clear fluid, with acid reaction, escaped from them. They did not rupture of themselves, and their cover offered considerable resistance to the lancet. The skin otherwise is perfectly normal and free from any appearance of inflammation. The only subjective symptom was a slight itching at times.

The diagnosis lay between eczema, herpes, sudamina, and dysidrosis, and this is carefully worked out by Jackson, who also gives a general account of the disease. He prefers the name "pompholyx," suggested by Robinson, but does not suggest any form of treatment.

PEMPHIGUS.

Sabin (*Jour. Cut. and Ven. Dis.*, 1886, p. 172) gives a case of "pemphigus followed by albuminuria," of which it may briefly be said that it was *not* a case of pemphigus, and that it was *not* followed by albuminuria. The case seems to have been one of the peculiar affection called by Bulkley "herpes gestationis," and by Duhring and other writers considered a form of dermatitis herpetiformis. The patient, a woman, suffered with brief attacks of a bullar eruption occurring in connection with three successive gestations. Six years after the last attack the patient died of Bright's disease, but no relationship between this and the skin-affection is shown.

In marked contrast to Sabin's paper is the thorough and complete study of "pemphigus vegetans (frambœsioides)" given by Neumann in the *Vierteljahresschr. f. Derm. u. Syph.*, Jahrg. xii. S. 157.

The affection is that formerly known as "frambœsia syphilitica," "mycosis syphiloides," etc., two chromo-lithographs of which are given in Kaposi's atlas under the name of "syphilis cutanea papillomaformis." It is not, however, syphilitic in its nature, and should be carefully differentiated from syphilis. The disease presents the following features. A few linseed-sized blebs appear, which at first are

flaccid, but later fill up and then break or are rubbed open. After a few days the raw spot takes on a warty growth, vegetating with some rapidity, and becoming hypertrophic and spreading in serpiginous forms. These vegetations secrete a thin ichorous fluid, which dries into an easily removable crust.

The earliest points to be attacked are the labia minora and majora, the oral and buccal mucous membrane, the lips, the axillæ. Later, the vulva, the anus, and the mucous membrane of the rectum are attacked. Even the vaginal portion of the uterus does not always escape.

In the male the oral mucous membrane, the neighborhood of the symphysis pubis, the inner surface of the thighs, and the nates are first attacked, so that at first sight the eruption looks a little like eczema marginatum. Occasionally the scalp is involved. The process goes on in the oral cavity, fauces, pharynx, etc., until a pitiable condition of excoriation and fissuring is produced, and when, by reason of closure of the nasal cavity by the lesions, mouth-breathing is practised, the lips and mouth become so sore that even food is taken with difficulty. As the affection goes on, every portion of the surface may be involved, the vegetating element, however, becoming less conspicuous and the lesions becoming mere blebs and excoriations, so that the surface may look as if burned to the second degree. In the latter stages of the disease, which is fatal, the lesions may take on a kind of gangrenous action, and an intolerable stench pervades the patient's apartments. Finally death ends the painful scene.

The closely-grouped lesions of pemphigus vegetans, when these are seated about the mons veneris, thighs, and anus, resemble closely the eruption of condylomata lata. The following points will aid the diagnosis:

1. The growths of P. vegetans spring from the surface, only surrounded by the bleb-wall; those of condyloma are surrounded by an infiltrated ring.

2. The loss of epidermis and epithelium in P. vegetans gives the growth a stippled appearance which is absent in condyloma lata.

3. Condylomatous growths as the result of syphilis represent a certain activity of the disease-process, and are usually accompanied by other symptoms; while also the tendency of the syphilitic eruption is to disappear in the long run, P. vegetans tends irresistibly from bad to worse, with constant decrease in the patient's strength.

Neumann gives notes of several cases of the nine which he has seen, and adds chromo-lithographs and microscopic sections illustrating the appearance of the lesions and their structure. He says that most of his cases were supposed to be syphilis, and much pain was caused by unfounded suspicion, not to speak of painful family scenes. This will excuse the rather full abstract above given.

LICHEN—LICHEN RUBER—LICHEN SCROFULOSORUM.

Vidal, in an article extracted from a forthcoming work on diseases of the skin (*Annales de Derm. et de Syph.*, t. vii. p. 133), appears to take quite a different view of the disease from that taken by the Viennese school. It is known that the Germans confine the use of the term lichen to one or two forms of disease, while the older English writers made it include a number of affections which the Vienna school masses under the all-inclusive designation of eczema or of prurigo.

Vidal takes quite a different view. He includes the prurigo of the Germans under lichen, and divides the latter affection into two main varieties: 1. Lichen simplex; 2. Lichen multiformis. The first of these he subdivides into acute, partial and general, and chronic, partial and general. The second variety is subdivided into mild and severe (*mitis* and *ferox*).

The varieties are described at some length, and with frequent use of expressions believed to have been long since obsolete, so that in reading this chapter one rubs one's eyes and wonders whether one has waked up in the times of Willan and Bateman.

This sort of thing will not succeed. It is useless to attempt to return to forgotten and forsaken nomenclatures and classifications.

A letter by Unna ("Sur la question du lichen") in the same volume of the *Annales* (p. 585) is chiefly taken up by a defence of an earlier article on the subject, but in it he gives expression to the following, which is worthy of attention by some of our younger dermatologists, who return from Vienna with the notion that all knowledge begins and ends there.

"That which we must guard ourselves against above all things is the influence of the 'school.' For the novice in science the school, with its established principles, its authoritative teaching, is an excellent institution, but it is a positive clog to the adept." In speaking further of the absence in Hebra's work of due acknowledgment of the labors of foreigners, Unna says, "The reason of this lacuna in the second edition of Hebra's work is to be sought alone in the peculiar custom of the Viennese school,—a custom which the 'system' of Auspitz and the younger Hebra's book are beginning to break through. This peculiar custom consists in declining to take the descriptions of foreigners in their intended meaning, but forcing them with more or less success into Hebra's classification, and adapting them to it whether or not. Our knowledge of impetigo contagiosa, of morphœa, of urticaria pigmentosa, of lichen planus, of myxœdema, of the dermatoses, of filaria, etc., which we owe exclusively to the English, renders this preponderance which they wish given to the local experience of Vienna quite untenable."

Brocq maintains, against Unna, the view that lichen ruber acuminatus is the same as pityriasis rubra pilaris.

Cases of lichen ruber and lichen scrofulosus have been reported by Boeck in the *Monatshefte* (Bd. v. S. 435), and by Gottheil in the *Journal of Cutaneous and Venereal Diseases* (vol. iv. p. 133). Boeck's series of cases are interesting as presenting the milder type of the disease similar to that met with in this country, and also as confirming some of Unna's views regarding the varieties of the disease.

COMMENTS ON SOME OBSTETRIC OPERATIONS.

BY GEORGE H. ROHÉ, M.D.

NOWADAYS the value of every medical or surgical procedure is determined by statistics. If a sufficiently large number of figures—whether these represent facts or not doesn't seem to matter—can be got together in favor of any surgical operation or plan of medication, no one dares question the conclusions drawn unless he can present a larger number of figures apparently proving something else.

At first sight there is nothing so unsympathetic as figures. As a matter of fact, figures themselves, in their proper places, never lie. But mortality statistics comprise something beyond the bare figures of so many cases, so many recoveries, so many deaths. They must take into account the circumstances of the cases in the literal meaning of the word,—*i.e.*, "matters attending an action that modify it for better or worse." This important point is too often completely lost sight of. The claims of partisans are always one-sided, and disfavoring events are ignored or suppressed.

Coming back, however, from this slight digression, I must point out first the power of precedent in obstetrical art. When it is considered that the problems to be solved in the delivery of a fœtus are so largely physical, it is certainly remarkable that the dicta of authorities are held in such profound veneration, and thinking for one's self is such a rarity.

The views to which I would give expression in this paper are the result of considerable reflection, and, although perhaps based upon insufficient personal experience, will, I trust, commend themselves as the result of the application of common sense.

The dictum of the old English master of the art, that "All meddlesome midwifery is bad," might, I think, be appropriately modified so as to read, "Ignorance in midwifery is bad." No one should be permitted to undertake the conduct of a case of labor who is ignorant of the mechanism of the process. This seems a bald truism; and yet it does not seem entirely superfluous in the light of our every-day experience.

I venture to assert, as a general rule, that in obstetrics there are no operations of election: either an operation is indicated or it is not indicated. It is the obstetrician's duty to make himself familiar with the conditions indicating the appropriate procedure to be adopted in any special case.

In all cases of labor, normal or abnormal, nature should be given a fair chance to do what she can towards effecting delivery. This does not mean that an unreasoning confidence is to be placed in the natural powers, but that no premature intermeddling should take place until the capacity of nature to deal with the case has been carefully measured. It does not

mean, either, that even in perfectly normal cases the accoucheur should leave matters entirely to the natural resources of the mother. Judicious aid rendered at the proper time, whether in the way of supporting the perineum, compressing the abdomen, expressing the placenta, or applying a binder after delivery, will be not only grateful to the patient, but often extremely valuable, although sometimes characterized as "meddlesome."

Let us take, however, a case in which nature's obstetric powers are insufficient, and in which art must step in to render assistance. How shall we be able to determine upon the indications for the various procedures?

In cases of slight disproportion between the head and parturient canal, if artificial delivery is necessary, it is usually held that the choice of operations lies between the application of the forceps and version by the feet. If each case be carefully and understandingly studied, however, it will be found that there is no choice allowable in a true scientific employment of the obstetric art, but that either the one or the other method must be adopted. There is no alternative.

Should the head present in an appropriate position, and the disproportion be due to a large head or slight uniform contraction of the pelvis, the os be well dilated, and the head engaged at the brim, but arrested there or in the cavity, the operation indicated is extraction with the long forceps. So long as the disproportion is not considerable enough to prevent the delivery of an unmutilated child, forceps extraction is not an operation of election, it is one of necessity, and the practitioner who considers any other procedure in such a case can lay no claim to being a scientific obstetrician.

If, on the other hand, there should be antero-posterior flattening of the pelvis, with moderate shortening of the transverse diameter so that the head cannot engage, or a malpresentation of the cephalic extremity such as a face- or brow-presentation, the correct indication would be to perform version and delivery by the feet. The indications for this operation are not, however, sufficiently known to allow a general rule to be laid down. Further study and observation are necessary.

The range of these two procedures is limited by a pelvic coarctation to three and one-fourth inches in the antero-posterior diameter. It is true that several obstetricians claim to have delivered living children by version in cases where the conjugate diameter was less than three inches; these are exceptions, and cannot be considered in establishing a general rule.

When the pelvic contraction is below three and one-fourth inches, or the diameters of the child's head are much greater than usual, on account of disease or malformation (hydrocephalus or certain forms of monstrosity), the disproportion between the head and the genital canal must be adjusted by one of the bloody operations either upon the child or the mother,—namely, craniotomy or Cæsarean section. Unfortunately, the diameters of the pelvis are not the only factors to be considered in establishing the indications for craniotomy. In some cases the child's head, as just pointed out, must also be taken into account. Inasmuch as in a large proportion of cases no trustworthy estimate can be formed of the size of the head in utero, it is sometimes difficult to reach a satisfactory conclusion, for so long as there is hope that the child may be saved and the life of the mother not endangered by the delay, craniotomy will be deferred. This doubt is more apt to arise in the lesser degree of pelvic contraction. When the conjugate diameter is less than three and one-fourth inches no hope may be entertained of delivery of an unmutilated child by the natural passages, and either craniotomy or some substitute for it must be performed in order to give the mother the best chance of life.

When the antero-posterior pelvic diameter is between two and a half and three and one-fourth inches, most obstetrical authorities advise craniotomy; if less than the former, Cæsarean section. With a pelvic canal of between two and a half and three and one-fourth inches antero-posteriorly, and no great encroachment upon the canal laterally, the child's body, decreased in size by perforation of the cranium and excerebration, can be delivered *per vias naturales* with comparatively little danger to the mother. The older statistics of craniotomy give a mortality of mothers as high as twenty per cent. Churchill's table gives two hundred and eighty-six cases with fifty-five deaths (19.2 per cent.); but this includes one hundred and twenty-eight cases with thirty-one deaths (twenty-

five per cent.) from the Dublin Lying-in Asylum, a hospital notorious for its high mortality-record. Smellie had forty-four cases with four deaths (nine per cent.), Churchill himself the same percentage, and Dr. Ramsbotham thirty-four cases with five deaths (14.7 per cent.).

Of the more recent statistics may be mentioned Schauta's, who had a mortality of 10.9 per cent. in seventy-three cases operated upon in the second Vienna obstetric clinic between 1876 and 1881.

In 1880 the late Professor A. F. Erich published a paper in which he gave the histories of eighteen consecutive cases of craniotomy in private practice without a single death. Between the date of publication of those cases and his death Dr. Erich performed the operation twice to my knowledge, both without any ill effect to the mothers. In one of these cases, in which I assisted, the woman (primipara) had been in labor for twelve hours. The patient had been under the care of a midwife, who had, in accordance with the custom of that class of practitioners, administered ergot in order to hasten the slow labor. The membranes had ruptured hours before, and the genital passage was hot, dry, and tumid. The head was large, and was arrested at the brim, into which it was forced firmly by the forcibly-contracting uterus. The patient was irritable and feverish. Version could not be performed. The antero-posterior diameter was not much diminished; I judged it to be about three and one-fourth inches. With the long forceps of Hodge earnest attempts to deliver were made, but without success. The indications were plain that craniotomy should be performed. The cranium was skilfully perforated by Dr. Erich, the brain broken up and evacuated, and in a few minutes a large child was delivered. The mother recovered without an unfavorable symptom.

The other unpublished case of Dr. Erich above referred to occurred in the practice of Dr. Shertzer. Owing to absence from the city at the time, I did not have the good fortune to see this case, which was described to me as one of extreme pelvic malformation. This case also recovered.

About two years ago, I had an opportunity of assisting Professor Opie in a case to which he had been called in consultation by the attendant, a physician with a large obstetric practice. The patient had been in labor for thirty-six hours. The forceps had been faithfully tried after the labor ceased to progress naturally, but without avail, although the pelvic space appeared ample. Professor Opie diagnosticated a hydrocephalus, and, after perforating and evacuating a large quantity of water, a dead child was speedily born. The patient, who had been much exhausted by her tardy labor, rapidly recovered.

In the summer of 1885 my aid was requested by a professional friend in the case of a colored woman in labor with her first child. She had been in travail about twenty hours when I saw her. The forceps, which had been frequently applied before my arrival, were again tried repeatedly, but without avail. No progress was made, although the pelvis was roomy and the cranium was not impacted. I suggested version, and on attempting to introduce my hand into the uterus discovered a large dropsical head. Perforation was indicated and performed, and, although the woman lived in a dark and damp basement-room in a filthy alley, she recovered promptly.

Five years ago I delivered a woman by craniotomy upon the after-coming head after decapitation. The patient had been twice delivered by craniotomy before by Professor Erich, and had declined the advice to have labor induced in the seventh month. The forceps were persistently applied, but on account of a considerable antero-posterior contraction the head could not be made to engage. I am now convinced that the persistent use of the forceps in this case was bad practice. Hoping to deliver a living child, I turned by the feet without much difficulty, but failed utterly in getting the head through the brim. The child was large, and perforation could not be accomplished before decapitation had been performed. The head was then perforated, and the skull broken up with Meigs's forceps and delivered. The patient, however, succumbed to shock, doubtless induced by the prolonged efforts with the forceps and the version. I am confident that an early craniotomy would have saved this woman's life. It was the operation indicated by the circumstances of the case.

A case similar in some respects was seen with Professor Erich. The patient had been in labor about twelve hours under the care of a midwife; but, as the head did

not engage, she wisely refrained from giving ergot. The forceps were applied under anæsthesia, and efforts made by both Dr. Erich and myself to deliver, but without success. Dr. Erich, with his usual practical sagacity and clear vision, saw that craniotomy was indicated, and proposed that operation. I appealed to him, however, to try and save the life of the child if possible. Contrary to his judgment, he yielded, and performed version without trouble, but considerable difficulty was met in extracting the child, which was born dead. The woman suffered considerably from shock, but rallied, to succumb on the fourth day to septicæmia.

To the twenty-three cases of craniotomy here related may be added three cases recently reported by Dr. H. J. Garrigues, of New York, none of which proved fatal. We have then twenty-six cases, with but a single death (3.8 per cent.). If in one of the cases the indicated operation had been performed at first, probably there would have been no fatal case to record in this series.

Craniotomy is contra-indicated when the conjugate diameter of the pelvis is less than two and a half inches. It is true that in some cases where the contraction is greater than this the mutilated fœtus could be delivered; but generally the operation is fraught with grave dangers to the mother. In Parry's statistics of seventy cases of craniotomy in pelves measuring two and a half inches and under, twenty-seven died, a mortality of 38.6 per cent. Doubtless, with antisepsis, much more favorable results could be obtained; but for these cases Cæsarean section is indicated; for while the dangers to the mother are very little increased by this operation, a considerable proportion of children might be saved. The more recent statistics of the Cæsarean section with suture of the uterine wound and its peritoneal covering are very favorable, although the American operators have fared very badly. Out of fifty operations by thirty operators since 1880, fifteen women were lost, a mortality of thirty per cent. But forty-three (possibly forty-six) children have also been saved. Of five operations done in the United States, however, all of the mothers and three of the children were lost. However, in the three lying-in institutions of Leipsic, Dresden, and Innspruck, out of twenty-four cases only one woman died, and all the children were saved,—a result so remarkable that one would be tempted to question the accuracy of the statistics if they were given on the authority of a less trustworthy writer than Dr. Robert P. Harris, of Philadelphia.

In all pelvic coarctations below two and a half inches in the antero-posterior diameter, then, the Cæsarean section should be performed; it is the only one indicated in these cases. But between two and a half and three and one-fourth inches craniotomy must still be regarded as the only operation compatible with safety to the mother.

The foregoing remarks are applicable to cases in which gestation has been completed or labor has begun. If the patient is known to have a contracted pelvis and the physician is consulted before the termination of the pregnancy, another procedure, the induction of premature labor, must be considered. This is indicated when the antero-posterior pelvic diameter is greater than three and one-fourth inches. In a pelvis having a shorter diameter than this, the delivery of a living or viable child is rarely accomplished by premature labor. The increased danger to the child at that age with a pelvis narrowed to three and one-fourth inches is due to the compression to which the head is subjected in passing through the canal. Inasmuch as the induction of premature labor is accompanied by more danger to the mother than craniotomy, the latter is indicated in pelvic diameters between two and one-half and three and one-fourth inches. If below the former diameter, Cæsarean section should be performed, primarily in the interest of the mother.

From the facts above stated, the following conclusions may, I think, be justly drawn:

1. The forceps, properly used, are the best means to aid nature in effecting delivery in head-presentations where the disproportion between the head and the genital passages is not too great to prevent delivery of an unmutilated child by the natural passages. In certain cases, especially of antero-posterior contraction, podalic version is the properly-indicated procedure. But in the present state of obstetrical art no definite rule can be laid down for the guidance of the practitioner in these cases.

2. In cases of pelvic contraction down to two and a half inches antero-posteriorly,

or of cranio-pelvic disproportion from other causes, if the forceps has failed, craniotomy is the only rationally-indicated operation, irrespective of the life or death of the fœtus. Fruitless waiting until the child dies by process of nature is reprehensible, and may, by adding dangers to the mother, become criminal. In these cases Cæsarean section is not an operation of choice or election.

3. In cases where the coarctation of the pelvis is extreme,—below two and a half inches,—or where there is extensive carcinomatous disease of the cervix or rupture of the uterus, the modern Cæsarean section with suture of the uterine wound, hysterectomy (Porro), or gastro-elytrotomy is indicated. Here also the operation decided upon should not be delayed until the dangers to the mother are too much increased.

4. In cases where the antero-posterior contraction of the pelvis is not below three and one-fourth inches, and the condition is known to the obstetrician before the pregnancy has terminated, the induction of premature labor in the seventh or eighth month may result in the delivery of a living and viable child.

5. The high forceps operation, version, craniotomy, Cæsarean section, and the induction of premature labor can only in very rare instances be considered as operations of election. Each has its definite sphere, when it should be employed, and in which it cannot be substituted by any of the others. It is only in very exceptional cases, conditioned by special circumstances, that this rule is suspended. In these cases the judgment of the experienced obstetrician, after taking into account all modifying circumstances, must decide which procedure is to be adopted.

TRANSLATIONS.

Hepatic Abscess in Childhood.—Dr. A. Bernhard reports three cases of abscess of the liver occurring in children (*Jahrbuch. für Kinderheilkunde*, N. F., vol. xxv. 4), and observes that, although less disposed to suppurative inflammation of the liver than in later life, yet cases of liver-abscess in childhood are not of such rare occurrence as is usually believed. The predisposing causes are the same in childhood as in adults, except diseases of the gall-ducts and gallstone abscesses, which in children hardly ever occur. The symptom-complex is very varied. For diagnostic purposes the following will serve:

1. Chills, with irregular, intermittent fever, in diseases affecting the area of distribution of the portal vein, are the most important and most constant symptom of suppurative hepatitis, with the possible exception of pain in the liver.

2. In abscesses of the liver complicated with pleuritic exudation, the line of dulness may be higher in front than at the back, and is generally irregular. In such cases experimental puncture can be performed, and the diagnosis made clear, if from above serous, and from below purulent, contents are withdrawn. Such aspiration is without danger when antiseptic precautions are observed. The putrid character of the pus, and the absence of fetid breath and of the characteristic signs of pulmonary gangrene in the sputa, point to a disease beneath the diaphragm, and to liver-abscess as the probable cause.—*Deutsche Medizinal Zeitung.*

Successful Treatment of Diabetes.—An interesting note was communicated by M. Martineau, physician to the Lourcine, to the Société de Thérapeutique, upon the treatment of diabetes. Within twelve years he has had the good fortune of obtaining sixty-seven definitive cures out of seventy gouty diabetics treated by the lithiated arsenical water. The mode of administration had been suggested by Prof. Rouget. It consisted simply in placing in the upper globe of a seltzer-water apparatus (Briet's), holding about a litre,—

1. A packet containing twenty centigrammes of carbonate of lithia;

2. A tablespoonful of a solution of arseniate of sodium (twenty centigrammes in five hundred grammes).

This is to be drunk at meal-time, mixed with wine. The contents of the apparatus should be enough for three meals at least.

The diet is not changed, or is somewhat restricted as regards starch, sugar, and fruits.

No special treatment was followed, and it is to the above prescription that the results were to be attributed. The result is not obtainable by lithia or arsenic given separately. Having waited to test this thoroughly before recommending it to others, M. Martineau felt warranted in demanding for it a fair trial.—*Revue de Thérapeutique Médico-Chirurgicale*, March 15.

EDITORIAL.

CONDURANGO REDIVIVUS.

GERMAN medicine has generally been regarded as almost synonymous with therapeutic scepticism. It must cause surprise, therefore, when a drug held in so little esteem in this country as condurango should claim the serious attention of eminent practitioners in Germany as a remedy possessing specific virtues in gastric cancer. American physicians have not had a very happy experience with condurango: in fact, if we remember correctly, its meteoric appearance in our therapeutic firmament raised quite an ethical controversy, the *disjecta membra* of which still occasionally turn up at the mention of certain names. But, having for a number of years rested in "innocuous desuetude," condurango has during the last two years received considerable attention from such notable authorities as Rühle, Binz, Immermann, and Riess. The latter, who is medical director of the Berlin City Hospital, in an article published in the *Berliner Klinische Wochenschrift* reports a large number of cases presenting the symptoms of cancer of the stomach, in which the drug was used with good results. Riess states that, as the result of his experience in upwards of one hundred cases, the remedy was not without success in a single case. From full notes of eighty of the cases treated with condurango and one hundred and sixteen treated without this drug, he has constructed a table which shows the following instructive results:

Of a total number of 80 cases which were treated with condurango, 53 died (66.3 per cent.), with an average duration of treatment of 39.5 days; the remainder, 27 (33.7 per cent.), were discharged (24 "improved," and 3 "cured"); they were under treatment for 54.8 days on the average. Of 116 cases treated without condurango, 107 died (92.2 per cent.), the average length of treatment being 22 days; the remainder, 9 (7.8 per cent.), were discharged (5 "improved" and 4 "unimproved"), the average duration of treatment being 11.7 days. Thus the average length of treatment of cases using this agent was 43.4 days, or nearly double that of those not so treated (21.2 days). The proportion of cases benefited by treatment with condurango was much larger, and the deaths were notably fewer.

In about twenty-five per cent. of the cases in which a distinct tumor of the stomach could be made out, the growth diminished, according to actual measurement, during the treatment. In twelve per cent. the growth disappeared almost entirely.

Riess claims that the effects of the drug are not simply those of a stomachic tonic, but that it seems to have a specific action in modifying the local and constitutional manifestations of the morbid process, and even, in favorable cases, arresting the latter.

The method of administration adopted by Riess is the decoction (one to twenty), of which six ounces are given per day, combined with syrup of orange-peel. In some cases he gives it in tablespoonful doses every hour. Patients do not object to it, as they so often do to other medicines in this disease. Immermann advises the wine of condurango as a good preparation.

Remedies for cancer of the stomach are not so plentiful that the profession can afford to reject any one recommended so highly as this one is by competent and experienced practitioners, without a trial. Further observation may cause us to revise the unfavorable judgment pronounced upon condurango by American physicians fifteen years ago.

PRÆPERITONEAL LIPOMATA.

HEINECKE, Wernher, and others have called attention to these curious and little-known tumors as the cause of certain obscure chronic painful affections of the abdomen. In recent numbers of the *Allgemeine Wiener Medizinische Zeitung*, Thonmayer has recorded six observations and placed the whole subject upon a practical basis. According to this observer, its omission from systematic text-books constitutes a serious defect in medical teaching. Præperitoneal lipomata occur most frequently in the linea alba. They consist of little fat masses which press through small openings in the fascia and develop underneath the skin. In the linea alba they occur with greatest frequency between the umbilicus and the ensiform cartilage; rarely they are found above the symphysis. They are of small size, not often attaining the measurement of a walnut, and can more commonly be felt than seen; upon pressure they are often exquisitely tender. Their presence is of importance because they tend to draw after them little pouch like processes of peritoneum, and thus favor the development of herniæ. Quite aside from this danger, they are of clinical importance as causing pain, vomiting, and meteorism, and simulating various painful affections of the gastro-intestinal tract. The pain is due to traction upon and irritation of the peritoneal process, and may suggest colic, neuralgia, dysmenorrhœa, and the like. It vanishes upon the reposition and retention of the tumor, or upon its extirpation. Præperitoneal lipomata are to be diagnosticated from herniæ by their small size, their elasticity upon palpation, and their marked sensitiveness. Treatment consists in their reposition and retention by a compress and belt. Reposition by taxis is usually easy, and a small opening may often be detected at the site of the little tumor. Thonmayer's cases, with the exception of one in which death occurred from other causes, were at once and permanently relieved. In view of these statements, systematic examination of the abdominal wall, particularly in the median line, should be practised in all obscure long-continued painful affections of the abdomen.

NOTES FROM SPECIAL CORRESPONDENTS.

PARIS.

TREATMENT of Malignant Tumors of the Bladder.—At the late Congress of Italian surgeons held at Genoa during April of this year, Professor Novaro, of Sienna, presented a dog in good health in whom he had, some three months before, successfully transplanted the opening of the ureters from the bladder to the rectum. This is a very important fact for modern surgery as regards the history of cancer of the bladder. Signor Novaro said, "I do not believe in the usefulness of any palliative operation in these cases, and I think it is preferable to attempt a radical operation which consists in the complete extirpation of the bladder. I have several times done this operation in dogs, and I have succeeded in taking away the bladder after having placed the ureters in communication with the rectum. The operation should be done as follows: first, an incision in the hypogastric region should be made, circumscribing a large flap with its base above, taking in all the thickness of the abdominal walls. Having uncovered the bladder, the ureters are attached to the rectum and the bladder taken away.

"It is only recently that surgeons have dared to attack the urinary bladder to get rid of the neoplasms that may have developed themselves at the expense of its substance. The deep position of the organ and the complex nature of the operations explain the present abstention. But cancer of the bladder is, of all the growths that may take place in the bladder, one that seems to have the least tendency to generalize itself, so that complete extirpation of the organ seems to offer the very best chance of cure. Professor Guyon has shown why this is true. To understand it is easy when we remember that the bladder possesses an anatomical structure quite different from most of the other organic structures, for M. Sappey says that its walls are deprived of lymphatics. This is intended by nature to prevent re-absorption of the urine; and we all know also that it is just these lymphatic vessels that are invaded by the elements of malignant tumors, and by them they extend to the whole economy and render most surgical operations useless, or at best only palliative in nature. However this

may be, the clinical fact is certain that whenever cancer takes its birth in the bladder it is likely to remain there, during a long time at least. So that, if its complete extirpation is made possible, a radical cure is obtained for cancer of the bladder. It is true that to conclude from operations on animals to man is not so easy as it seems, but still it is not impossible to believe that, with modern methods of antisepsis and improvements in operations, this dreaded disease will have found a radical cure before many years."

Chloroform and Tracheotomy.—A long discussion at the Paris Surgical Society on this question, and a late clinic by Dr. De Saint-Germain, give some varied views as to the advisability of using chloroform in tracheotomy. M. Le Dentu brought the subject up at the Société de Chirurgie by reading a paper sent in by M. Housel, of Boulogne, who advocated its use. M. Le Dentu thought that it was never used, and several of the members stated that it was as old as Chassaignac, and that it was "current money" in America. The opinion was much divided, but most inclined to the ideas expressed by Dr. De Saint-Germain in his clinic at the Hôpital des Enfants-Malades, so we will give a *résumé* of what he said, as his great experience deserves attention. It may be stated that his method of operation is of the one time and one motion order. The doctor said, "I have been asked why I did not take part in the discussion at the Surgical Society on the use of chloroform in tracheotomy. Well, to tell the truth, my ideas were not clear at the moment as to what answer should be made to this proposal,—something like the people who only find their brains at the bottom of the stairs. I talked it over by myself afterwards, and now that I am more at home in our little amphitheatre I will tell you what I think about the matter. I may be pardoned first for stating that I have made four hundred and two tracheotomies, and I have given chloroform thirteen thousand times, so I am not afraid of it. In nineteen the operations were made in adults, and seven I saw made by Krishaber. I have always been astonished at the resignation and calm displayed by the patients during the operation, and, asking them about the pain, they mostly answered that it hurt less than to have a tooth extracted or to have a boil opened. I have never seen any occasion to give chloroform, nor have I seen it given, and think it would be more of an impediment than anything else. As to children, it is demonstrated to-day that there is no use in operating early, so we wait until the last moment,—that is to say, when asphyxia has already commenced,—and it is well known that the child is at that moment in a state of anæsthesia, so that in this group of cases there is no use for chloroform.

"I now come to the cases where the child is not in the state of *perinde ac cadaver*, but is strong and ready to defend himself. Suppose the surgeon called in the middle of the night by a distant doctor to operate upon a child suffering with croup. Upon his arrival he examines the child, who in fear defends himself, clinging to the curtains and suffering from suffocation, but not yet with asphyxia. The parents object to the operation, and it is possible to wait an hour or two longer; but the surgeon must then go home, perhaps to be called when it would be too late: so the operation is decided upon. And here chloroform might render good service, it might be thought; but, first of all, the surgeon will need two aids, and it must not be forgotten that, as he has chloroformed the child, he must do the slow and dry operation indicated by Trousseau. But what risks with an anæsthetized child you run! If you let fall into its trachea a flow of blood, of which it cannot have any consciousness, and which it will not, therefore, make any attempt to reject, I leave you to imagine what happens if this blood is not expelled.

"Of the considerable number of children that I have operated upon, two died on the operating-table notwithstanding all I could do to save them: the first one from a mass of false membrane that the canula pushed down, and which I could not extract; the second from a syncope that seemed to take place on contact of the knife with the skin. Since that time I always address the parents about as follows: 'Your child will be certainly lost if it is not operated on at once, and tracheotomy gives it one chance in five of cure; but I must tell you that the operation itself is not without danger: for, notwithstanding all the care I may take, it is possible for the child to succumb in the middle of it. But, no matter what that danger is, I should not hesitate to perform the operation on my own child if it were in the state which yours is in at present.' I don't remember any parent that objected after such a speech; but if we add the danger of chloroform to the operation, can we say the same thing? No."

As a sort of *post-scriptum* to the above, it is interesting to say that Professor Brown-Séquard has made a number of experiments in his laboratory on dogs and monkeys, by which he proves that an incision of the skin made along the middle line of the neck will at once bring about an anæsthesia of the region in a radius of six to seven centimetres. Dr. Brown-Séquard was astonished to find, in the accounts given of people who committed suicide by cutting the throat, that they sometimes went on almost to sever the head, and with most people he thought it was a sort of insane courage. But on investigating the matter by experiment he found that even a slight incision of the skin of the neck produced an anæsthesia of the region. This was also studied to see how analgesia could be produced. It results from the facts shown by

Dr. Brown-Séquard that the skin of the neck possesses, in common with the larynx, but to a less degree, the power to inhibit the sensibility. So, if the surgeon can make the part insensible by a bistoury-cut, what is the use of chloroform in tracheotomy?

Treatment of Cold Abscess.—Dr. Barette, the present *chef de clinique* at Professor Trélat's service, gives in a late article a good account of the cure of these abscesses, which are so common all over the world. First of all, he calls attention to the fact that these patients are not only attacked with a local disease, but that their constitutions are more or less involved: so that we should not look upon it only in the surgeon's light, but also give a general treatment, which must vary with the patient. Hydrotherapy is important, exercise out of doors, and daily salt-baths (five pounds of rock-salt to the large bath-tub of water). To this add good food, milk, etc. Almost all the preparations containing iodine are good, and the best is cod-liver oil, four to six tablespoonfuls per day. When the stomach refuses to digest it, then change to iodized glycerin (two grammes to one hundred and fifty of glycerin), or iodized wine (one gramme of tincture of iodine to a quart of good Bordeaux wine). Or use the syrup of the iodide of iron. Change of climate, the mineral waters, and above all the sea-side, is to be recommended for those who can go or be sent. The maritime atmosphere, charged as it is with sodium chloride and vapors of iodine, with ozone, seems to penetrate the organism and forces internal combustion to its highest limits. Besides, here is to be found one of the most active forms of treatment, the cold salt-bath. Quite recently Dr. Cazin, of the hospital at Berck-sur-Mer, a hospital at the sea-side mostly for children, and M. Lejeune, of the Institut at Ostend, another sea-side curative establishment, showed what excellent results could be obtained by such institutions. They also give a sort of mucilaginous bath, formed of sea-weed and water, which contains a strong proportion of the iodine principles. (There is a chance for some one to erect such hospitals at Atlantic City or Cape May.)

As to local treatment of these cold abscesses, at present the modern methods here are but two in number: one is the injection of ether-iodoform, and the other is opening and scraping out. The first is Professor Verneuil's method. He thinks that iodoform is the best substance to destroy the bacillus of tuberculosis, and he added the ether to it so that its vapor would carry the agent to the remotest parts of the abscess. The iodoform is also absorbed, as can be proved by the examination of the urine, where it will be found: its action is powerful in modifying the constitution.

The injections used are one of iodoform five, ether one hundred, and a strong one of one iodoform to one hundred ether. First Dieulafoy's aspirator is used, No. 3 needle, and without changing the trocar the injection is made, not over three or four grammes being used in the large abscesses. The walls then swell up to quite a large size, but no one need be alarmed at this, as it gradually goes off, and cure often follows. We will not describe the well-known system of surgical intervention by large incision and *grattage*, but we may state that in very large abscesses, where all surgical aid is impossible, we have seen these injections bring about a very considerable amelioration of the general health of the patients.

False Testimony of Children: its Medico-Legal Aspects.—M. Motet lately related to the Academy of Medicine some very interesting facts on this subject, that can be applied by any physician who may be called in to elucidate such cases. There is nothing more moving than to hear a child tell the details of a crime which he pretends to have witnessed or has been the victim of himself. The natural way in which he speaks, and the simplicity of all his facts, give confidence, and public indignation goes on increasing as he tells his simple tale. One can hardly believe that they often invent it all, but such often is the fact.

M. Motet tells of a number of cases to prove this. One is of a little boy of seven, who did not come home all one night, and the day after he was taken out of the river, where he had thrown himself with the evident intention of drowning himself. His story was that a man, of whom he made a correct description, had met him and carried him off by force, and that finally he had thrown him in the river. His description of the man was so exact that the police had no trouble in finding the person, who was employed in the neighborhood in a museum of anatomy; but he quickly proved an alibi and was released. M. Motet was charged with the examination of the child, and in questioning the mother he found that for some time back he had slept badly, and that he had incontinence of urine; besides this, he lived in conditions that must have worked on his young imagination, for his mother was a newspaper-seller, and every day he heard of all sorts of crimes and scenes of violence. To add to this, the man he charged had lately come to settle in the neighborhood with his wax-show of anatomical horrors, and the child heard him crying out one day, "Walk in and see the head of Morin, who was killed by Mrs. H." (a celebrated murder-case of last year). It happens that the boy's name is Morin, and here was the moral shock which led to the whole trouble. No doubt the child, haunted by fear, took to dreams, and the idea of some danger menacing him was implanted in him. So one

day he is taken with a fright, and runs off to end it by jumping in the river. (The youngsters who run off after a course of the ten-cent novels to kill the Indians furnish an example of the same type.)

A curious one of the same style is that of a young fellow who walked in his sleep. Seen at the Hôtel-Dieu a few days ago, he seemed healthy, but it was stated that at night he got up and walked asleep, or sometimes fell down in a sort of fit, during which he said people did all sorts of things to him, and it might have led to a charge of some criminal sort. The doctors were puzzled a little, and all sorts of diagnoses were made, including epilepsy and hysteria, etc., until it was found that he had worms, a cure of which took away all the symptoms. Certainly the moral is that a doctor is to be called in to investigate these cases, and not a lawyer.

A similar case was that of a young man who was locked up in prison on some charge of petty theft, and made charges against his guardians that they had entered his cell at night and made obscene attempts on him. Worms again; and these, combined with sensations of anal pruritus and his unhealthy imagination from reading novels and bad books, led to his making charges that could only be cleared up by a medical investigation. So that it is to the medical profession, after all, that we must look for the clearing up of these delicate questions.

We must all remember in regard to children that their growing intelligence is always ready to seize upon the marvellous side of everything, that fiction of all sorts charms them, and that they have a most astonishing facility in giving a body to fictions they hear or read. Again, the little ones are generally influenced by a nervous mother, who will question them in such a way as to suggest to them a certain line of ideas which they will follow. Witness the case here lately of the little boy who plays truant from school, and, returning, his mother fancies from his garments being deranged that some wicked attempt has been made on him. She questions him from this point of view, and he, not knowing what to say, assents to what she says, and on the father's return repeats all as she says it to him, and the poor man, scandalized, goes for the grand question, Who did it? and, forced, as it were, to answer, the child names a neighbor, who is at once arrested and has some difficulty in proving an alibi. Professor Charcot has frequently shown cases like this. Some weeks ago a young hysterical girl, during a period of mesmeric state, was told that she had been given a loan of fifty francs. Another day she was asked where and how she got a certain piece of gay ribbon she was wearing, when she at once stated that she had gone out one afternoon and bought it, and got it in a certain street which she named, and that she paid twelve francs for it. In analyzing this it was found that it all arose from the suggested loan of the fifty francs, which was never given to her; this had passed in her brain as a fact, and she at once invented the rest, as she had not been out of the hospital, and the ribbon had been left there for her by one of her relations without her knowledge. In legal medicine a careful study of these facts, with clinical experience, will mostly be enough to clear up many a difficult law case, if followed up with a little patience by a careful physician.

Treatment of Angina Pectoris.—Recent discussions before the Société Médicale des Hôpitaux have brought this question to the front. Two theories are brought forward to explain the very painful attacks that characterize this malady. One is the nerve-theory, which looks upon these manifestations as a neuralgia of the cardiac plexus, and attributes the serious cases to a sort of neuritis of the same plexus. This neuritis was discovered anatomically in 1863 by Lancereaux, and it was well developed by Professor Peter as long ago as 1871.

The second theory is the arterial one, which attributes angina to an organic stricture or a spasmodic one of the coronary arteries of the heart, and in general to all the various causes that bring about an ischæmia or anæmia of the myocardium. This theory, spoken of by Hunter, Parry, and others, had been abandoned, but has been taken up again by Germain Sée and Potain, and it has again been upheld by M. Huchard during the recent discussion. For this last author the attacks that have been observed in neuropaths, and which have been invoked to sustain the nervous theory, are *false anginas*, and these pseudo-anginas show themselves at all ages. They are characterized by the frequency of the attacks and by their periodic appearance, often at night; also by their duration, which is often very long, and by the seat of the pain, which is at the lower part of the cardiac region. The nature of these pains is similar to a sensation of fulness or tension of the heart; they are more painful than dangerous, and cure in every case, notwithstanding the medicine given or the doctor attending. A recent thesis calls them "angina of the chest of an hysterical variety."

What a difference there is between the real attacks of angina pectoris and these symptoms! says M. Huchard; for in true angina pectoris it is particularly to the age of the affection of the arteries, such as arterio-sclerosis, that we must look: as a great physician said about this, "A man has just the age of his arteries." Again, the attacks are not often spontaneous, and mostly come on after a quick walk or some unusual effort, or even a simple movement which is so quick that a patient of Parry's is reported to have said that "he felt the extremes of pain and feeling well in an instant." The pain is also exactly under the sternum, and it is agonizing while it lasts: as Seneca said, who was himself a sufferer, "For

all other pains one suffers, but in this one seems to give up his soul." Real angina left without treatment almost always terminates by death, and the explanation of its gravity is found in the concomitant lesion,—that is, the state of anæmia of the myocardium, which is proved by the sudden cases of death or faintness without pain.

The anatomical proofs are as convincing as the clinical, for M. Huchard has some ninety observations where the lesions of the coronary arteries are shown, and in experimental physiology the spasm of the coronary arteries is admitted. It is true, however, as M. Moutard-Martin says, that there do exist some cases of obliteration of these arteries in which no angina was observed, but it may be that here the collateral circulation had time to take place without bringing on any of the effects of cardiac anæmia. These theoretical ideas have an important practical importance, because if the attacks of angina are nothing more than anæmia of the heart's substance, and exist only in cases of aortic and arterio-sclerosis, they present a double elevation of the arterial pressure, and we must therefore abandon all the therapeutical measures that are capable of increasing *vaso-constriction* and arterial tension, such as digitalis, ergot of rye, and belladonna, and give, on the contrary, those medicines that produce *vaso-dilatation* and the diminution of the vascular tension. This is why nitrite of amyl and nitro-glycerin, which was spoken of by Lauder-Brunton, produced such good effects in attacks of angina pectoris, and for the same reason injections of morphine did good, but they could not cure the disease that the arterial trouble caused. For this purpose the use of the preparations of the iodide of sodium is proposed, as they have a special action on the arterial walls, while they cause the arterial tension to fall considerably, and the result of M. Huchard's experiments is that this preparation constitutes the real and only cure for this condition. He says that the potassium iodide when long continued becomes a heart-poison, and the sodium salt must be given. He gives it for fifteen to eighteen months at a daily dose of one to three grammes, with an interval of a week's rest in each month. His statistics give a result that the mortality has fallen from ninety-five to thirty per cent. of cases.

It must not be supposed that during this discussion M. Huchard and those who follow his ideas had it all their own way, for while some said that they had success with it, others, such as M. Guyot, said that they had given it without any success; but the near future will decide if M. Huchard is as correct and as sure of his facts as he says, for every case known is now being carefully studied, and further results will be ready in time for the International Congress meeting at Washington.

The Congrès d' Ophthalmologie.—There is a very interesting yearly meeting of this Congress now being held here, and a large attendance of eye-surgeons is present. We notice the name of G. T. Bull, of New York, who presents a new optomètre. Professor Panas, Landolt, and all the prominent men have presented papers, but they are too long for our letter. We will only call attention to some remarks of Dr. Abadie, of Paris, "on the importance of local medication in ocular therapeutics." He said that formerly they looked only to the constitution of the patient and the hope of a reaction of the organism, but now, while still taking into account the nature of the subject, an attempt is made to destroy the pathogenic element directly: as an example of this may be cited lupus of the face, which all the anti-scrofulous medicines do nothing to stop, and yet scarification and cauterization with the galvano-cautery will cure it readily. No ophthalmologist will deny the good effects of yellow precipitate in the scrofulous ophthalmias of children; and, thanks to the use of cocaine, new local applications can be tried. "So we have lately incorporated iodoform with lanoline, which has a great penetrating power, and we have obtained excellent results in tuberculosis of the iris with daily massage of the eye with a pomade made in this way. In the choroid diseases, where the mercurial medication is indicated it also combined with lanoline will permit the drug to penetrate into the thickness of the ocular membranes, where it is hoped the curative influence will be still greater. With lanoline we have all the elements of a new local eye-medication which is easy for all of us to apply according to the indications, and which should be fertile in good results, judging from what has already been seen."

THOMAS LINN, M.D.

PARIS, May 9, 1887.

PROCEEDINGS OF SOCIETIES.

AMERICAN SURGICAL ASSOCIATION.

THE Eighth Annual Meeting of the American Surgical Association was held May 11 to 14, inclusive, in the reading-room of the Army Medical Museum, Washington, D.C.

The Association was called to order at 11 A.M. on the 11th instant by the President, Dr. Hunter McGuire, of Richmond, Virginia, who delivered the President's Address, taking for his subject

THE NEED AND VALUE OF CO-OPERATIVE WORK IN SURGERY.

He spoke of the necessity and advantage of co-operative work, and afterwards suggested several changes in the management of the meetings of this Association. The day has

passed when the dictum of one man, no matter how exalted he may be, is received without question. Disease presents problems peculiarly difficult of solution, for we cannot apply to the human machine the fixed rules by which inanimate bodies are governed. The result of work in private houses and in public hospitals must be different. Besides this, it is necessary to get rid of the rubbish with which current literature is flooded by ignorant but ambitious contributors. This becomes a comparatively easy task, however, when we are confronted with the problem of knowing when to reject material presented by skilful but unscrupulous workers, who to gratify their own personal vanity make false returns of their labors.

In concluding his address the President made the following suggestions:

1. The appointment annually of a business committee to prepare the work of the Association. Two general subjects in surgery should be selected to be discussed at the morning sessions of the first and second days of each meeting.

2. The address of the President and other papers should be limited to half an hour, and those who take part in the discussions to fifteen minutes.

3. The abrogation of Article IX. of the Constitution will allow us to admit to Fellowship some men in this country who are really needed in the Association. Although believing in the rigid observance of the Code of Ethics of the American Medical Association, and the absolute necessity of its enforcement in that body, there is no need for it in our Association. The only code that we should have is scientific work.

4. The report of the committee with reference to the American Congress of Physicians and Surgeons should be adopted.

5. The constitution should be so amended that propositions for membership shall lie over for one year. The qualifications for Fellowship should be age, experience in surgical work, scientific attainments, with general culture.

A committee was appointed to take into consideration the suggestions offered by the President (Drs. S. W. Gross, C. H. Martin, D. W. Yandell, Moses Gunn, and C. Johnston).

The Association then went into Executive Session with closed doors.

Afternoon Session.

F. S. Dennis, M.D., of New York City, read a paper on

THE EXPLORATION OF THE BLADDER BY THE SUPRA-PUBIC METHOD.

The supra-pubic operation of to-day is practically the same as the old operation: the only change has been an improvement in *technique*. The first reported operation was that of Franco, in 1561. From that period to 1879 cases were not numerous, but from 1879 to the present time the operation has been done with such success as to attract attention throughout the world. The time is not far distant when practically the only two operations for vesical calculus will be supra-pubic lithotomy and litholapaxy. Supra-pubic lithotomy is simple in *technique*, safe in execution, free from injury to the reproductive organs, radical in results, curative in application, and brilliant in statistics. The many serious accidents attending the lateral operation are entirely avoided.

Technique of Operation.—For a few days before operation a milk diet should be employed. The day previous to operation the bowels should be moved with castor oil, and on the morning of the operation an enema should be used so as to empty the rectum for the introduction of the rubber bag, and the abdomen should be washed with an antiseptic solution. After the patient has been etherized, the surgeon should introduce a rubber bag into the rectum, above the internal sphincter, into which twelve ounces of warm water are to be introduced. This quantity will have to be increased or diminished according to circumstances. The danger of rupture of the rectum in elderly people and in young boys should be borne in mind. The urine should be withdrawn, and six ounces, more or less, of an antiseptic solution introduced into the bladder. The catheter may be left in the bladder and stopped with cork, and this will serve as a guide to cut upon. The distention of the rectum and bladder increases the distance from the pubes to the anterior cul-de-sac of the peritoneum to three inches. The incision should be made in the median line, and should extend for three or four inches above the pubes. When the transversalis fascia is reached, the use of retractors (on the principle of the eye-speculum) facilitates the operation. Having divided the fascia, the end of the catheter can be felt and cut upon as a guide. The bladder may then be seized with two tenacula and opened. Where free exploration is desired, sutures are introduced on each side of the incision. The stone is removed either with the fingers or forceps. The bladder may then be washed out. A catheter should be introduced through the urethra, but not left longer than twenty-four hours, on account of the danger of exciting traumatic urethritis. In most instances the wound of the bladder should be left open. In cases of calculi the condition of the vesical tissues is such that primary union is unlikely. In certain other conditions, such as rupture, the wound may be closed, for here the condition is different. The abdominal opening is to be closed and a tube introduced.

The operation is indicated (1) for hard, large calculi, and in persons suffering with paraplegia and deformities rendering lateral

lithotomy difficult; (2) for removal of certain foreign bodies, such as hair-pins, etc., or for the treatment of chronic cystitis; (3) in cases of tight stricture, fibroma of prostate, tumors of the bladder; and (4) for rupture. In its extraordinary simplicity, its reduced mortality, its freedom from danger, and its safety for the general practitioner, it compares well with litholapaxy.

The speaker had collected one hundred and twenty-four cases of supra-pubic operation for stone done since 1879. Previous to this date the rate of mortality was thirty per cent. Since then the mortality has been reduced, there being eighteen deaths, a mortality of fourteen per cent. Seven of these deaths may be justly excluded, giving a mortality of nine per cent. According to Sir Henry Thompson's statistics, the death-rate from the lateral operation is twelve per cent.; according to the same authority, the mortality of lithotomy is six per cent. In considering the mortality of this operation, two facts are to be considered. The mortality may be improved by more rigid antiseptic precautions. The second fact is that the operation has been limited to the largest stones. When the smaller stones are included the death-rate will be reduced.

Specimens and models showing the position of the bladder under various conditions were then shown.

John H. Packard, M.D., of Philadelphia, presented a paper on

SUPRA-PUBIC CYSTOTOMY FOR OTHER PURPOSES THAN THE REMOVAL OF CALCULI.

The history of the operation as it appears in cases recorded from 1750 to 1886 was briefly discussed, and the opinions of authors in regard to the hypogastric operation in general, and especially with reference to the evacuation of urine, were next given. In regard to the anatomical relations of the peritoneum to the bladder and abdominal walls, much diversity of opinion was found to exist.

In 1883 the speaker had removed by supra-pubic cystotomy a piece of shawl-pin five inches in length, which had been passed through the urethra. Since then he has done this operation a number of times. In cases of retention of urine from stricture, where a fair attempt to pass an instrument fails, he draws the urine by aspiration. In a short time subsequently an instrument can usually be passed. He did not recall a case in which it was necessary to repeat aspiration.

The following cases were cited:

July 7, 1855. Mr. G., 85 years old, had retention due to enlarged prostate. The bladder was greatly distended. The urine was drawn off with a long catheter; but, as he desired more permanent relief, supra-pubic cystotomy was performed, and a glass ovariotomy tube bent like a tracheotomy tube was introduced. The patient improved decidedly, but suddenly died July 9, from heart-failure the result of sudden exertion.

J. C., aged 43, came under observation January 21, 1885, at the Pennsylvania Hospital, with a history of retention the result of old stricture. The bladder was greatly distended, and no instrument could be passed. There were frequent chills and profuse sweats. The next day Dr. Thomas G. Morton made a perineal incision, opening an abscess; the catheter then passed into the bladder. The following day the bladder was again distended. Supra-pubic incision was then done. A catheter passed through the abdominal opening, and the neck of the bladder came through the perineal wound. On February 7 a large mass of slough came from the abdominal wound. The patient then rapidly improved, and was discharged cured April 21.

H. F., 43 years old, had retention for four days. The penis, scrotum, and skin of abdomen were swollen, tense, and rigid. Free incisions were made: the bladder was opened and a tube introduced. On June 4 an instrument was passed by urethra; on July 13 the patient was discharged, and has continued well.

Mrs. S., aged 63, admitted with enlarged prostate and frequent attacks of retention. August 13, 1886, supra-pubic incision was performed and the bladder opened. Although the condition was improved, the patient died of exhaustion August 29.

The next two cases occurred at the Pennsylvania Hospital within the past few weeks.

W. E., aged 70, was admitted April 24, 1887, with retention due to enlarged prostate. Supra-pubic cystotomy was performed and a large quantity of putrescent urine removed. A rubber tube was passed into the bladder. The urine contained albumen to the amount of one-half its bulk; granular casts were also found. A typhoid condition developed, and the patient died on the fourteenth day after admission.

R. W., aged 40, was admitted the same day. He had double inguinal hernia and double hydrocele. He had passed no urine for fourteen hours. Catheterization was attempted without success. Supra-pubic incision was then performed, and a rubber tube introduced. He has done well since then, and is beginning to pass some water by the urethra.

Concerning the method of procedure, the fullest antiseptic precautions should be observed in these cases. In most of the cases on which the author had operated, the question whether or not the bladder should be distended had not presented itself, as the bladder was already over-distended. The bladder should never be more than moderately distended, not more than six or eight ounces of a boric-acid solution being employed. To retain the water in the bladder, a convenient method is to bend the urethra on itself and hold it in this position. There

seems to be more advantage and less risk from the distention of the rectum. Many writers recommend that the bladder be steadied by an assistant; but this was regarded as needless and objectionable.

The incision through the skin should be free enough to give ready access to the deeper parts. When the bladder is reached, it is desirable to secure it in some manner before puncturing; for this purpose a small double hook may be used. A small tenaculum may answer. When a large opening is to be made, a double ligature is perhaps the best device. In cases of retention, the curved trocar and canula may now be at once used. The canula should afterwards be substituted by the tube. The speaker's custom is to make the opening in the bladder just large enough for the tube. The proper point for making the opening seems to be about at the middle of the exposed portion of the wall of the bladder, which would be about one inch or one and one-half inches above the pubes.

The drainage-tube should go well into the bladder, and have lateral openings only near its extremity. The external end may be closed with a cork or clip or by bending it. In old men with atonied bladders he had sometimes used glass tubes. If a large opening has been made in the bladder, it may be closed around the tube with a few catgut sutures. The tendency of the wound is to close quickly, except where the tissues as well as the general system are in bad condition. The edges of the wound in the skin can be apposed with sutures of catgut or silkworm-gut.

In concluding, the speaker asked, "If the supra-pubic section had been first tried and generally adopted, is it likely that the perineal operation would have been afterwards performed, on account of its greater ease, simplicity, and efficiency?"

The next paper,

TO WHAT EXTENT CAN WE CLASSIFY VESICAL CALCULI FOR OPERATION? WITH A REPORT OF CASES AND REMARKS ON THE DIFFERENT METHODS EMPLOYED,

was read by A. Vanderveer, M.D., of Albany, New York, who communicated the detailed histories of forty-one cases upon which he had operated. The various methods employed were lithotomy, rapid dilatation of the urethra, and Bigelow's operation (litholapaxy). Among them there were seven cases of perineal lithotomies, with two deaths (of very old men with large calculi) and five recoveries. Of attempted litholapaxies and an immediate perineal lithotomy there were two cases, both resulting in death,—one occurring in the speaker's practice, the other in the practice of a friend. Both were large stones, the patients presenting a history of much suffering through many years. Of dilatation of the urethra in the female and washing out of fragments or removal of stone entire there were six cases, all recovering with no complication whatever. Of urethral calculi in the male there were four cases, all recovering. Of simple lithotrity in the male there was one case, followed by recovery.

Of litholapaxies attempted but not completed there were four cases, three ending in death, and one (the stone hiding in a sac) later underwent perineal lithotomy and recovered. One was probably complicated with some form of tumor of the bladder and a history of chronic disease of the kidneys. One was a case of chronic alcoholism, one was complicated with sacculated bladder, and the last two were cases of surgical kidney of the gravest character.

Of the litholapaxies in the male there were eighteen patients, having twenty-two operations, four requiring a second operation. Of the number sixteen recovered and two died; of the latter, one after the first and one after the second operation.

With reference to supra-pubic lithotomy, the author said that the operation must necessarily deal with severe cases of large, and in some instances sacculated, stone. He did not believe that we should ever expect from it as great a percentage of recoveries as from rapid lithotrity. A table of reported cases of supra-pubic operations was given, showing in one hundred and forty-two adult cases a mortality of twenty-two per cent.; in children under fifteen years of age, one hundred and thirteen cases gave a mortality of 10.5 per cent.

The operation of litholapaxy is certainly indicated where the stone is small or of moderate size. Contrary to the teachings of a few years since, this can be done in very young male children with proper instruments. In male adults, if there is severe chronic cystitis, no matter what is the size of the stone, the supra-pubic or some form of perineal lithotomy seems best. The cystitis can then be successfully treated, and there is less danger of a recurrence. The speaker thought that it would be found by future statistics that cystitis has much to do with the necessity for a second or third operation. He thought that the condition of contracted bladder in the male with adhesions had not received the attention which it demanded. This must in some instances embarrass supra-pubic lithotomy. On anatomical grounds, the supra-pubic operation will be much simpler in the youth, as the bladder is much higher in the pelvis at this time of life. In girls rapid dilatation or supra-pubic lithotomy will undoubtedly reach all cases. In adult women vaginal lithotomy may be added.

The discussion of these papers was postponed until Thursday morning.

Adjourned.

(To be continued.)

OBSTETRICAL SOCIETY OF PHILADELPHIA.

MEETING OF APRIL 7, 1887.

(Continued from page 550.)

LABOR COMPLICATED BY LARGE HARD HEADS.

DR. M. PRICE was called to this patient three weeks before her delivery. She informed him that she was in labor, and that her time had expired. Examination showed the cervix but little dilated, the os not being larger than a silver quarter. There was quite a discharge from the vagina. The pains were at short intervals, and were unquestionably labor-pains. The woman was in good condition, and he had no doubt that labor would go on. He left, giving instructions to send for him if the pains increased, and that if not sent for he would call next day. He had attended this woman in two previous pregnancies, both children being large and the labors tedious: so he anticipated that this one would be a slow labor. The next day the pains were less than on the previous day, and there was no change in the cervix. He did not hear again from her for three weeks, when the husband called and stated that his wife had been in labor all night and all day. He now found the cervix wide open, but the presenting part of the child so high up that he was not able to say what part was presenting. Passing the entire hand into the vagina, he found a vertex second, but the head would not engage. After waiting two hours, he found the head had been pushed to the side of the pelvic inlet, with the occiput resting on one side and the neck and shoulders on the other, and determined to ascertain the difficulty. He pushed his hand up into the womb, and had no difficulty in bringing the head back to its first position, but found that it was completely ossified. There was no pulsation in the cord that he could detect, and he at once decided to deliver by turning, as he thought he could deliver the child in that way sooner than in any other. He at once secured the feet, and soon had the body and arms delivered. The forceps were applied to the after-coming head, and it was delivered after quite a pull at the superior strait, but with ease through the soft parts without the instruments. There was no injury to the mother, and she made a rapid recovery. The child was still-born. Its head measured sixteen inches in occipito-frontal circumference. There can be no doubt that the mother's pelvis is much above the average size, as a head perfectly ossified could not have passed through a pelvis of less than sixteen and one-half inches, as the soft parts would take up at least one-half inch. Standard authorities give the circumference of the female pelvis at the inlet at from thirteen to thirteen and one-half inches.

ABDOMINAL SECTIONS.

Dr. JOSEPH PRICE: In reporting a mixed group of cases treated by these methods, of which Dr. Tait has been the first and chief advocate, I desire to make brief reference to Dr. T. Gaillard Thomas's article on "Laparotomy as a Diagnostic Resource," published in the *Medical News*, Philadelphia, December 11, 1886. Therein Dr. Thomas expresses in full Mr. Tait's views. They are simply, without the mention of Mr. Tait's name, an embodiment of the views given vent to by Mr. Tait while on a visit in America in the autumn of 1884. Dr. Thomas would select the text of Mr. Tait's law, his own axiom, as a motto for the walls of a hospital devoted to abdominal surgery: "When a doubt as to the diagnosis of an abdominal neoplasm of serious character or of certain obscure pathological conditions of the abdominal cavity which threaten life exists, give the patient the benefit of explorative incision." Mr. Tait, in like clean and terse English, expressed the same view in a clinical lecture at the Hospital of the Jefferson Medical College, September 15, 1884, when he said, "My experience teaches me that it is a surgical crime to allow a patient to go to her grave without operation where it offers a possibility of relief."

Dr. Thomas, with great frankness, reports five cases as examples of the class in which he had to regret non-interference on his part: cases in which "we" or "I" decided against operation. The patients died. Further he says, "I regret to say that I could more than double the number of cases illustrating this part of my paper. Few such cases occur to me now, for the very reason that I am a strong advocate for explorative incision as a diagnostic resource."

As to another class of cases in which Dr. Thomas meets with happy results, he reports as follows: "There is a class of cases in which in my hands explorative incision has yielded such brilliant results that I shall devote full consideration to it. I allude to cases of ascites in the female."

Mr. Tait, in the address I have referred to, gave as an example in point a case operated upon four years previous. "The patient, a young lady, had an enormously enlarged abdomen, due to ascites,—a fact I had recognized. I opened it by incision for exploration and drainage: by this means the fluid is evacuated just as well as with the trocar; but you cannot feel anything with a trocar; but with a clean cut of two or three inches you can introduce one or two fingers and find out the actual condition of the pelvic organs as you can in no other way."

The pioneer work done by Mr. Tait, his influence in exploratory work and treatment of diseased conditions of the tubes, is referred to by Mr. Greig Smith in a very fair and generous spirit. "Tait's name is mainly connected with inflammatory diseases of the tubes, and his influence has been strongly felt in the substitution of operation for actual disease as against vague nerve-symptoms."

I am strongly of the opinion that an incision which admits only two fingers and not the whole hand is a sufficient incision. Dependence upon fingers skilled in manipulation will serve best and effectively guard against danger in any pelvic operation. Herein I differ from Dr. Thomas, who urges, "Make an incision which will admit the whole hand: one which will admit two fingers only is hardly warrantable." There is great danger in multitude of fingers of irritating the bowels with the hand, and further running great risk by exposure.

Many fatal results attend men beginning the study and practice of surgery of the abdomen. This is illustrated by the statement of an abdominal surgeon: "I do not count my first thirteen cases, because I was learning how to do it." In this there was considerable Rip Van Winkle arithmetic; "We won't count this one." The present good results in the hands of young surgeons must not be attributed to the taking advantage of all the so-called "latest antiseptic improvements." In this relation I will make brief allusion to an experience with well-trained young surgeons, six in number, doing nine pelvic operations due to inflammatory trouble, suppurating, adherent, and matted together pelvic viscera. The operations were all completed with but one death, notwithstanding they were all bad cases.

In illustration, I present a specimen of

PYOSALPINX,

removed by Dr. Thomas G. Morton. This patient had an enormously-enlarged abdomen. She had been seen by a prominent gynæcologist, who had plainly stated that there was no ovarian trouble, and recommended tapping, which was done. It is my impression that by the first tapping the large cyst was ruptured; the dropsical accumulation followed. Dr. Morton found upon examination, after repeating the tapping (the patient refusing any other operation), a small tumor or collapsed cyst. He refused to repeat the tapping, and urged section. He kindly asked me to see the patient. Upon examination, I was fully satisfied of the correctness of Dr. Morton's diagnosis, and agreed with him in urging section. It was immediately done. Extensive adhesions had developed from the tappings; free hemorrhage followed. He removed a large collapsed cyst, and by irrigation large quantities of old clot. An interesting feature of the case was the existence of two pedicles, the pelvic and a fan-shaped one over the diaphragm and stomach. The case presented very interesting and instructive features. Result, cure.

PYOSALPINX.

The next case, Mrs. D., white, æt. 18 years, on October 31, 1883, presented herself at the Philadelphia Dispensary, complaining of attacks of free bleeding and of pain in the left groin and left submammary region, intensified by locomotion. On examination, the uterus was found low down and retroverted; the left ovary was tender. On June 16, 1885, vulvo-vaginal gland enlarged and tender; abscess incised and packed. On July 1, 1885, she complained of pain in the back, left shoulder, and left inguinal region. She was put on general treatment. Menstruation was normal. November 9, 1885, examination showed the uterus retroverted and the ovaries tender; vulvo-vaginal glands enlarged; abscess incised and packed. November 25, 1885, the uterus had been treated for its displacement, and at this time was found in good position; both ovaries were enlarged and tender; the right ovary was the largest, the left the most tender. February 24, 1886, uterus drawn slightly to left. May 24, 1886, complained of pain on coition. January 25, 1887, pain in right inguinal region. On examination there were found tortuous, cystic, boggy masses filling up the whole right side of the pelvis.

January 26, 1887, Dr. Price opened the abdomen in the median line, the incision being enlarged to three and a half inches on account of deep adhesions to all of the pelvic viscera. The right tube charged with pus and the right ovary with a parovarian cyst as large as a cricket-ball were removed, the pedicle ligated with silk and dropped. Free irrigation was employed, the wound was closed with silk, and no drainage used.

PYOSALPINX.

(Reported for J. S. K. MORTON, M.D.) Mrs. T., white, æt. 36, complains of pain in right iliac region and extending down the right thigh, increased by locomotion. General condition bad; dissipated.

Examination.—Uterus in good position; to right of cervix is a firm, pedunculated tumor, filling up the pelvic cavity on that side, firm, nodular, and adherent.

Operation, January 25, 1887.—A two-inch incision was made two inches above the pubis; two fingers were introduced, and everything found practically normal except the right ovary and Fallopian tube. The ovary was as large as a pigeon's egg, and firmly bound down in every direction, and apparently more cystic than normal. The tube was likewise bound down, extremely thickened, and contained fluid. After carefully examining all around the adherent mass, a point more friable than the other adhesions was found and torn up. This done, the enucleation became a matter of patience and application of judicious force until the whole mass had been shelled from its inflammatory bed. When thus freed, the ovary and tube were brought out of the wound and the pedicle doubly ligated as near the uterine cornu as possible, and divided with scissors. Previ-

ous to dropping back the pedicle, the remainder of the Fallopian canal in it was thoroughly swabbed out with strong bichloride solution, eighteen grains to the ounce. Scarcely any oozing took place, and after thoroughly irrigating with water that had been boiled and carefully sponging, the peritoneal cavity was found to be perfectly dry. The incision was closed without a drain. Time, fifty-five minutes.

Progress.—Occasional slight nausea was the only untoward symptom following the operation; evening temperature, 99.4°; next morning, 100°. After that it did not rise until the evening of the fourth day, when it mounted to 102°, and she complained of considerable abdominal pain, with much vomiting. This set-back had come on as a result of getting up and walking about the room some hours before, during the absence of her nurse. The fifth day found her with marked symptoms of peritonitis, vomiting, and towards evening shock and evidently dying. Death occurred during the night.

Post-Mortem.—Parietal wound in good condition; about half a pint of cloudy serous fluid in the peritoneal cavity; abdominal contents matted everywhere with very recent lymph; no blood or clots; kidneys somewhat granular, but not nearly so much so as might have been expected from her dissipated manner of living; other organs practically normal.

(To be continued.)

PHILADELPHIA ACADEMY OF SURGERY.

A STATED meeting of the Philadelphia Academy of Surgery was held May 2, 1887. In the absence of the President, Dr. S. W. Gross occupied the chair.

Dr. F. H. Gross exhibited a

TUMOR OF THE ABDOMINAL WALLS,

and made the following remarks:

"I have here a tumor which I removed at the German Hospital three days ago. It was more interesting before removal than it is now, on account of its situation. The patient was a woman, aged 46 years, married, who had twelve children, eight of whom are living; the other four died in infancy or early childhood. The patient was a large, healthy-looking German, weighing one hundred and forty-five pounds. She first noticed this growth in the abdominal walls about twenty years ago, at which time it was no larger than a pea. It was situated about two and one-half inches above the umbilicus, and a little to the right of that point. The tumor grew very slowly, and two years ago had only reached the size of a walnut. It remained of this size until three months ago, when it rapidly increased to its present dimensions, about those of a small fist. Within the past two months there appeared shooting and darting pains extending around the abdomen; previous to this there was no pain connected with the tumor.

"The deep attachments of the growth were very deceptive. Those who examined it believed that it was attached to the peritoneum, and at the operation we were prepared to remove it, even if it extended so deep. At the operation, however, it was found external to the sheath of the rectus muscle. It appears to be a fibrous growth which is undergoing myxomatous degeneration."

Dr. F. H. Gross also exhibited the growths from a case of

MULTIPLE LYMPHOMATA OF THE AXILLA.

"The patient from whom these growths were removed was aged 43 years, the wife of a clergyman in the interior of the State. She is the mother of eight children, all living. Her parents also are living. She first noticed a swelling in the right axilla about the middle of December, 1886, seventeen months ago. At this time there appeared to be two growths the size of a walnut. They gradually increased in size until they gave rise to considerable inconvenience on account of their bulk. There was no pain. She desired to have them removed. I expressed the opinion that they were lymphomata. There were also two growths above the clavicle not larger than hazel-nuts.

"I made a straight incision in the axilla on the thoracic side and removed two dozen of these glands, the largest being the size of a goose's egg. It is remarkable that the glands above the clavicle, which I had expected to remove by a later operation, have almost entirely disappeared. The operation was done eleven days ago, and the glands are now not larger than a small bean. There is no taint in the family. I think that the origin of the tumors must have been due to indifferent causes.

"I had a similar case a year or two ago, in which the patient subsequently died of phthisis. The wound did not heal, and there was a continual discharge from it. In this case there is no tubercle."

Dr. S. W. Gross: "My own experience is that, independently of Hodgkin's disease, mutliple lymphomata such as we meet with in the neck, and which are so easily enucleated, are exceedingly uncommon in the axilla. The majority of tumors of the axilla connected with the lymphatic glands that I have operated on have been tubercular glands undergoing cheesy degeneration and lympho-sarcoma. I have yet to see a case like this, and I have seen a good many cases of tumor of the axilla. At my first clinic in January this year I had a case of lympho-sarcoma of the axilla, and I remarked to the class that lymphoma, of which I had shown a good many cases situated in the neck, I had never seen in the axilla. Drs. Senn and Cheadle, who were present, agreed with me."

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

A STATED meeting was held April 25, 1887, the President, LAURENCE JOHNSON, M.D., in the chair.

EXTERNAL URETHROTOMY—A PLEA FOR ITS PERFORMANCE IN MINOR TRAUMATISMS OF THE URETHRA.

Dr. L. BOLTON BANGS read a paper with this title. The first proposition offered for discussion was that the operation should be resorted to earlier than it usually is. He had become convinced from the observation of cases in the hospital that their condition was rendered infinitely worse by the passage of time, when the deeper urethra became fixed in a semi-cartilaginous mass which a subsequent operation could never properly overcome. The early operation should be performed for acute traumatism: after falls astride wagon-wheels and other objects; after kicks and blows on the perineum; after penetration of the perineum and wound of the urethra by sticks, etc. The urethra being damaged to a greater or less extent after these injuries, the process of repair sets in at once, but to be interrupted or interfered with periodically by the necessity for the urethra to perform its function. The bladder expels its contents sometimes with great violence, and thus irritation is set up, which finally results in inflammation and the formation of cicatricial tissue in and around the urethra.

Not only should external urethrotomy be resorted to at once after known injury of the urethra and extravasation of urine or inability to pass the catheter, but there are also cases in which the only evidence of injury of the urethra might consist in the escape of a few drops of blood from the meatus. An instrument of large or fair size may pass easily into the bladder, yet experience shows that subsequent trouble will be avoided only by this operation. The slight injury to the urethra might result in a follicular inflammation; a little pus-cavity forms; the urine passing over the urethra makes this condition worse; and there may finally develop extravasation and cicatricial tissue. The object of external urethrotomy is to obtain rest for the urethra and prevent liability to extravasation and its subsequent unfortunate results. The operation should be performed as early as possible, and the first physician who is called to the case, if possessed of a slight amount of manual skill, and having with him a guide and a scalpel, would be able to perform it without difficulty. The operation also should be resorted to when opening a perineal abscess in a patient with a stricture of large calibre, for it is not sufficient to evacuate the abscess and perform catheterism; the urethra should be divided in order to prevent the development of more deplorable results.

The second proposition upon which the author invited discussion was that external urethrotomy is comparatively devoid of danger, although not absolutely so, as this could not be said of any operation on the human body. Its dangers, as well as its difficulties, had been overstated. On looking over hospital records he had found that deaths following the operation had occurred in patients with preceding kidney-disease, probably arising from the urethral disorder or other devitalizing disease, and were not due to the external urethrotomy.

DISCUSSION.

Dr. F. N. OTIS fully coincided with Dr. Bangs with regard to the probable benefit to be obtained by early operation in cases of external injury of the urethra. Our most difficult and refractory cases of urethral trouble are those of traumatic origin. The resultant stricture is often so extensive that it cannot be fully divided, and will return. To illustrate the importance of an early operation, he referred to a case in an English hospital, that of a patient who had a perineal swelling, and the surgeon, taking it for a difficulty outside the urethra, independent of extravasation, applied a poultice to prepare the abscess for the knife. But by the next day extravasation had taken place, and the patient died. He thought the operation was a safe one.

Dr. E. L. KEYES could not take exception to any of the statements made by the author of the paper. He thought the operation of external urethrotomy should be performed early after injuries of the urethra, and also in cases of stricture of the deep portion of the urethra calling for either divulsion or division. The operation he regarded as simple, although when a guide could not be introduced it was attended with some difficulty.

Dr. Keyes further said that the former custom of dilating deep urethral strictures is falling gradually into disrepute. If the tissues were not tight, if the stricture was not resisting, the patient might get along without suffering special inconvenience by passing a moderate sound; but when the stricture was tight, the patient was liable at any time, by passing sounds of increasing size, to get up a urethral chill, an inflamed testicle, and all sorts of complications. Such accidents were not likely to occur if the deep urethra were divided by external urethrotomy. The operation of divulsion in such cases had pretty much fallen into disuse, and internal urethrotomy in his experience was disastrous. If he himself had a deep urethral stricture, he would vastly prefer to have it cut externally to having it divulsed or cut internally to a sufficient extent.

Dr. CHARLES MCBURNEY was glad to hear ideas which were gradually and surely gaining the approval of surgeons expressed so clearly by Dr. Bangs. He thought external

urethrotomy for traumatism of any moment was a highly proper procedure. It was proper because it was the only means of avoiding dangers which were immediate and also remote. Regarding the operation itself, he thought something might be said which would tend to lessen the fears of the patient and those of physicians not accustomed to perform it regarding its severity. The object of the operation was only to provide for perfect drainage of the urine and products of inflammation. It was not done for the purpose of dividing the stricture. There might be a stricture three or four inches in length in the deep urethra, but it was not necessary to try to divide it when performing external urethrotomy. The latter operation was performed for the purpose of drainage, and a small opening was sufficient. The stricture could be divided by internal urethrotomy. External urethrotomy need not involve a single important structure; hemorrhage could be controlled without any danger. If these facts were borne in mind, he thought the operation would lose some of its terrors.

He (Dr. McBurney) thought there were some cases of slight traumatism of the urethra which did not call for external urethrotomy, but they were very difficult to define. He might say, however, that in a case of injury to the perineum in which there was no evidence of laceration of the urethra other than perhaps the escape of a few drops of blood, in which there was no tumefaction of the urethra, in which it was perfectly easy to pass a large instrument, and in which there were no crevices to engage a small instrument, in such a case he would not do external urethrotomy. But he would wash out the bladder after each evacuation.

Dr. BANGS, in closing the discussion, said he was glad to see such uniformity of opinion with regard to the propriety of external urethrotomy in the class of cases under discussion. In further illustration of its importance, he said a man had recently come under his observation who fell upon the table five months ago, striking the perineum, in consequence of which there resulted slight tumefaction and scalding on urination. No blood escaped from the meatus. He was catheterized by the attending physician, and then passed from under his notice. To-day it was difficult to pass a filiform bougie. External urethrotomy would now be performed.

BALDNESS: WHAT CAN WE DO FOR IT?

was the title of a paper read by Dr. G. T. JACKSON. Alopecia prematura alone received attention. Premature baldness, it might be said in a general way, was that occurring before the forty-fifth year, although the period was arbitrary. Subdivisions were made into idiopathic and symptomatic. The idiopathic form began unannounced by any antecedent disease. Many families had it for generations. The different causes claimed for it were named, but the author gave particular attention to the influence exerted by want of proper care of the hair, as this was under the control of the patient and was a part of prophylaxis and treatment. He was inclined to think that due attention to proper care of the scalp and general hygiene of the body were more reliable than any so-called remedies. Women gave more care to their scalps, and not only was baldness less common among them than among men, but the results of treatment were better. In families in which baldness was hereditary, prophylaxis should commence at birth with proper cleansing of the scalp, the use of soap and water, the brush and comb, and the avoidance of all things which might injure the scalp. The shampoo need not be repeated more than once or twice a week, and, after drying, some unguent, as sweet or olive oil, should be applied.

What not to do was nearly as important as what to do. Pomades, as they were liable to become rancid and injure the scalp, should not be used. Wetting, twisting, pulling, scorching the hair, as fashion demanded, were injurious. Close-fitting hats and caps should not be worn. Anxiety of mind should be combated by cultivating a cheerful disposition.

Baldness due to dandruff, syphilis, typhoid fever, etc., next received attention. In addition to treatment appropriate to the special disease, he again urged the importance of systematic care of the scalp and hair.

DISCUSSION.

Dr. FOX said that when baldness was evidently due to some seborrhœal condition, to want of cleanliness of the scalp, the shampoo would do a great deal of good. When due to shock or other nervous state, we should have to rely upon hygiene. Then there was a large class of cases which dermatologists had tried to explain in different ways, but he thought their explanations were pretty much on an equality: they did not explain it. He, too, once thought that baldness was due to disappearance of the subcutaneous tissue and tightness of the scalp; but on examining patients he found in many of them the scalp quite movable. Nor did he believe it was due to high hats or compression of the blood-vessels by the head-apparel. In brief, he did not believe baldness in many cases could be accounted for any more than an explanation could be given for the musical talent in some and for the mechanical in others. Patients should reconcile themselves to the homely statement that "what cannot be cured must be endured."

Dr. CARPENTER inquired whether the custom among some physicians of cutting the hair short during or just after an attack of

typhoid fever had any beneficial effect upon the hair.

The PRESIDENT was a firm believer in high stiff hats as a cause of premature baldness, and as a basis for his belief said that baldness was much more common now than twenty years ago.

Dr. FOX doubted whether baldness was more prevalent now than twenty years ago, and Dr. JACKSON said that high hats had been worn by young people in England almost for centuries, yet baldness was not apparently on the increase. He and Dr. Fox both thought no benefit was derived from cutting the hair in typhoid fever.

NEW YORK ACADEMY OF MEDICINE.

A STATED meeting was held April 21, 1887, the President, A. JACOBI, M.D., in the chair.

ON THE PRACTICAL VALUE OF OUR PRESENT METHODS OF TREATING THE UPPER AIR-PASSAGES.

The subject was one referred for discussion to the main body by the Section in Laryngology, of which Dr. B. Robinson was chairman. In the absence of Dr. Robinson, the discussion was opened by a paper by Dr. Francke H. Bosworth.

Dr. BOSWORTH said it is now thirty-three years since Garcia demonstrated the feasibility of examining the interior of the larynx during life, and Czermak, availing himself of Garcia's teachings, presented to the medical profession a new method of treating disease and inaugurated a new specialty. He thought it was highly proper to stop for an instant and take an account of what progress had been made in this specialty. The early days of this specialty were days of instrument-invention, and so rapidly did the number of appliances and ingenious devices for treating diseases accumulate that the impression grew that we treated disease by machinery. Nor was this impression ill founded. Dr. Bosworth thought that when we knew little about the treatment of these diseases our machinery was very extensive. As our knowledge increased the machinery disappeared, until now all of it might be carried in a hand-satchel.

He then spoke of special methods of topical applications in the treatment of the larynx, lower pharynx, vault of the pharynx, and nasal passages. Although speaking of the treatment of these separately, his conclusions with regard to each were the same: namely, that so-called chronic catarrhal inflammation of the larynx, lower pharynx, and vault of the pharynx was due to disease of the nasal passages; that chronic nasal catarrh was due to nasal obstruction, and the only radical means of relief consisted in removing such obstruction. This was to be accomplished by the use of the knife, saw, snare, or cautery. It was true the spray and the douche had their uses, but in no case had they ever cured chronic laryngitis or so-called chronic pharyngeal catarrh. Their action was only palliative and cleansing. No local applications directly to these parts ever cured such inflammation. It was not claimed for them by anybody that they would cure tumors, syphilis, tuberculosis, or paralysis. He had before said that the lower pharynx was in no sense a part of the air-tract. As he had but recently written on the subject of the surgical treatment of obstructions of the nose, he would now devote most of his remarks to the action of the cautery.

He claimed that the cautery destroyed only the superficial layer of the lining membrane of the obstructed nasal cavity, and that therefore its action in overcoming obstruction was not due to its destruction of tissue, but to its coagulation of the superficial structures, their contraction upon the dilated blood-vessels and hyperæmic tissues, in the manner that a film of collodion acts. This being the case, he claimed that the galvano-cautery was an expensive, especially a cumbersome, apparatus; one which could not be used with delicacy and exactitude; which was not without danger; and consequently its use should be dispensed with and chromic acid substituted. The latter possessed every advantage of the galvano-cautery and platinum wire, and had not their disadvantages.

With regard to apparatus for making spray, he showed a hand-atomizer with a single rubber bulb, which he claimed was as effective as the most costly air-pump and receiver; and, for examinations, a head-mirror two and a half inches in diameter was as good as the more costly.

Dr. A. H. SMITH continued the discussion with a brief paper, in which he said there was growing scepticism as to our ability to cure all cases of so-called catarrh of the upper air-passages. Then, referring to the benefit to be derived in the treatment of chronic or subacute affections of the lining membranes of those passages by the employment of anodynes and disinfectants, especially by weak solutions of carbolic acid, he pointed out the limitations of such benefits. To show that surgical methods were not indicated in all cases or capable alone of curing diseases of the upper air-passages, he quoted the statistics of certain institutions, going to show that out of thirteen hundred and fifty-one cases only twenty-seven per cent. were considered as calling for an operation. It followed that in over seventy per cent. of the cases other treatment than surgical was required. Any person familiar with the subject must have seen patients with chronic nasal catarrh returning month after month, and year after year, to dispensaries and institutions, having

nowhere been able to find complete and radical relief. This was not true alone of the specialty of laryngology and rhinology. The same thing was seen at clinics for diseases of women,—patients returning for months with chronic uterine catarrh, etc. He believed that a change of structure took place; that the vital conditions were altered, and they could not be restored by any measures which we had yet adopted or perhaps would ever discover. In other words, there were certain difficulties and limitations inherent in the case not chargeable to faulty methods of treatment or to want of skill. He had long since ceased to expect, as he had ceased to promise, complete and permanent cures.

Dr. WILLIAM H. THOMSON discussed the subject from the stand-point of the general practitioner. In his opinion, the treatment of chronic diseases of the upper air-passages should be directed chiefly by two principles: first, by taking cognizance of cutaneous nerve associations in the causation and perpetuation of inflammation of the mucous membranes; and, secondly, local disinfection.

Organs which were in symmetrical pairs, such as the hands, feet, ears, and eyes, were so closely associated in vaso-motor relations that the same effect, as far as their circulation was concerned, was produced in both by an impression made on only one member of the pair. Second, there was a close relation between the sensory nerves of the skin and the vaso-motor apparatus of the viscera immediately beneath. Third, there were special relations between the vaso-motor functions of one part of the body and the nerves of sensation in a particular distant part of the body. Wet feet, for instance, might check menstrual flow. This relation also existed between the feet and the larynx, and between the nerves at the nape of the neck and the circulation in the nose.

Unfortunately, we have few vaso-motor tonics. In colds it would be of benefit to apply cold water to the nape of the neck on rising, keeping the hair dry, and to apply cold salt water to the throat. The neck and shoulders should be washed in cold water, dried, and then rubbed with sweet oil. Draughts of air were more harmful than a walk out in the cold air. Exposure of a portion of the surface of the body, especially at night, should be avoided. As to special covering, a thin woollen undergarment should be worn, and over that a perforated buckskin shirt. Buckskin drawers, perforated, might also be worn. He knew of no special clothing so beneficial as this. Chest-protectors, etc., which covered only a part of the surface, were worse than useless.

Speaking of disinfectants and their application in the treatment of diseases of the upper air-passages, he said it was hard to resist the belief, from the evidence already given, that the product of inflammation, as such, was always the result of infection. As soon as a particular tissue began to lose its normal amount of vitality, the enemy (micrococci) found it out and began its work. A practical deduction was that, as the onset of disease could be prevented only by excluding germs, so all chronic mucous inflammations could be got rid of only by driving out such germs after they had obtained access to the tissues. Two methods were to be adopted: first, strengthen the vitality of the parts; second, apply disinfectants directly to the affected parts. The greatest advance, he thought, would be made in the discovery of disinfectants and how best to use them.

Dr. H. H. CURTIS had deduced the following conclusions from the observation of a thousand cases of disease of the upper air-passages. In all cases of nasal stenosis from deflection of the nasal septum, etc., there was subacute or chronic inflammation of the lining membrane of those passages, this inflammation extending also down to the pharynx, and here giving rise to glandular hypertrophy. This affection of the posterior wall in the faucial cavity was due to mouth-breathing, and disappeared on opening up the nasal cavities. Any treatment directed to this glandular hypertrophy without treatment of the nasal passages was without success. Disease of the ethmoid cells was generally due to hypertrophy of the middle turbinated body and consequent occlusion and prevention of exit of the ethmoidal secretions. The treatment consisted in the application of chromic acid to the thickened middle turbinated body in order to reduce the obstruction and allow free access of air and outlet for the secretions. He employed this escharotic to the exclusion of others, and he would be unwilling to exchange it for all the sponges, sprays, etc. Its use was followed not only by clearing up of the nasal passages, but also, in consequence of this, by disappearance of the granulations referred to, of laryngitis, pharyngitis, huskiness of the voice. The chromic acid should be used carefully, but he had not seen any bad results from it. The sooner the profession ceased to apply strong astringent solutions and nitrate of silver to the upper air-passages, and gave proper attention to restoring the respiratory functions of the nasal passages, the sooner would laryngology be placed on a higher plane and relief given to countless thousands suffering from so-called post-nasal catarrh.

Dr. W. C. JARVIS thought the spray was undoubtedly of great utility when properly employed. Pound-pressure, he said, meant nothing; but the dimensions of the pneumatic tube and the pound-pressure being given, we had everything. Cocaine would act better, more efficiently, and a less amount would be required when used by the spray than by any other method. Another remedy

to be used from the spray was rhigolene, and it was often to be preferred to cocaine, especially where the latter failed to produce anæsthesia. He could not do without the spray for cleansing purposes. The coarse spray possessed nearly all the advantages of the douche. Powders were best applied fine by the compressed-air spray. Iodoform was best tolerated. Chromic acid and nitric acid had their uses. But chromic acid was a treacherous drug. Doubtless it was of benefit in some cases; but it should not be used for the relief of hypertrophy of the lining membrane. It was a specific in its action on papillomatous tissue. Regarding the comparative value of surgical with other methods, he thought the decision had been pretty well settled in favor of the former. Where weeks and months were required to cure by local applications, relief and cure came from a single sitting when the snare, saw, or cautery was used. The apparently increased discharge in nasal catarrh was due to accumulation by obstruction, not to hyper-secretion. He spoke of the value of applications of vaseline or other unguents and agents for cleansing and protective purposes.

AUTOGRAPHS OF DISTINGUISHED PHYSICIANS.

The PRESIDENT, in accepting on behalf of the Academy autograph articles of three distinguished physicians, presented by members, expressed the hope that other members would follow their example. The autographs of distinguished members of the profession of to-day would be just as valuable a hundred years from now as were those now of distinguished physicians of the last century.

NEW YORK PATHOLOGICAL SOCIETY.

A STATED meeting was held April 27, 1887, the President, T. MITCHELL PRUDDEN, M.D., in the chair.

ANTHRACOSIS OF THE LUNGS.

Dr. PETERSON presented the lungs of a man, aged 67 years, who had died suddenly in the street. The post-mortem examination showed fatty degeneration of the heart, to which the sudden death was attributed. The liver was fatty. Both kidneys showed signs of senile atrophy. The interest in the case related to the lungs, which were almost black in color, being stained with carbon. The cut surface stained the fingers black when passed over it. In places the lung was composed almost entirely of fibrous tissue and carbonaceous matter, resembling to the touch a cirrhotic liver. In one there was an abscess the size of a hazel-nut. The man had worked during thirty-one years in the cleaning department of a stove-works, in which he was compelled to inhale an atmosphere so filled with carbonaceous matter and fine particles of sand as to render vision obscure. The large force of men employed in the same room all had some pulmonary difficulty.

RENAL CALCULUS.

Dr. IRA VAN GIESON presented a large white kidney, containing in the sinus a cylindrical calculus five centimetres in length, one cubic millimetre in diameter, sending off two prolongations about one cubic millimetre in length into the calices. There were connective-tissue indentations on the surface of the kidney corresponding to the branches in the calices.

PHOSPHORUS-POISONING.

Dr. VAN GIESON also presented specimens from the body of a man who died four days after drinking water containing phosphorus. At the autopsy there were observed fatty degeneration of the heart and liver; parenchymatous degeneration of the kidneys; swollen and granular changes in the cells and follicles of the stomach, Brunner's glands, and pancreas. The lesions were those usually seen in phosphorus-poisoning, but two points of interest in the case were, first, tubercles found in only one bronchial gland, and not elsewhere in the body, thus bringing us face to face with the first stage of tuberculosis following phosphorus-poisoning; second, the presence of minute hemorrhages in the lymph-channels of some of the cervical glands.

Dr. CARPENTER asked Dr. Van Gieson whether he based his diagnosis of tubercle on the presence of the bacillus tuberculosis. Dr. Van Gieson replied that he had not examined for the bacillus. Dr. Carpenter said he thought the ground assumed by some, that a diagnosis of tubercular tissue should never be made except on the basis of the presence of the tubercle-bacillus, was unjustifiable; that in many cases the anatomical elements alone were sufficient basis for the diagnosis, although the bacillus should be looked for when practicable; but the absence of this was not conclusive evidence that the tissue was not tubercular.

DEATH FROM DIPHTHERIA IN A CASE IN WHICH INTUBATION WAS PERFORMED.

Dr. BROTHERS presented a part of the respiratory organs of a child, aged 19 months, which had, when he first saw it, croupy symptoms, evidence of limited pneumonia, and was becoming cyanotic. O'Dwyre's tube was inserted into the larynx through the glottis, relieving dyspnœa, but the patient died two days later. The autopsy showed no false membrane on the tonsils or pharynx, but there was a false membrane covering the larynx, trachea, and larger bronchi which could not be removed. There was a spot of pneumonic consolidation in both lungs. The case did not speak against the value of intubation of the larynx.

HYPERTROPHY OF THE LEFT VENTRICLE, CIRRHOSIS OF THE LIVER, CHRONIC NEPHRITIS, ETC.

Dr. FRANK FERGUSON presented fresh specimens removed from the body of a man, aged 48 years, who had been a confirmed drinker for eighteen years. His illness dated back three years, but during the last three weeks of life his legs became greatly swollen. There was enlargement of the abdomen and of the scrotum to the size of an adult's head. He had not passed urine for three days prior to admission to the hospital, and the bowels had not moved for five days. He was semicomatose, in which state he died. There was found advanced chronic diffuse nephritis, intense hyperæmia of the kidneys, also of the mucous membrane of the stomach, with thickening of the lining membrane of this organ. There was great hypertrophy of the left ventricle of the heart; the valves were normal; the muscular tissue of the heart was anæmic. The liver was very much advanced in cirrhosis, being composed almost completely of fibrous tissue. There was a great quantity of fat in the scrotum, on the right side there being two large lipomata. The pancreas was unusually firm. The suprarenal capsules had undergone extensive fatty degeneration.

REVIEWS AND BOOK NOTICES.

THE SCIENCE AND ART OF OBSTETRICS. By THEOPHILUS PARVIN, M.D., LL.D., etc. Illustrated with Two Hundred and Fourteen Wood-Cuts and a Colored Plate. Philadelphia, Lea Brothers & Co., 1886. Pp. 701.

This new text-book aims to represent in brief the present state of the science and art of the science for which the author believes "maieutics" (*μαιευο* and *μαιευτής*) a more appropriate title than the common one. The work consists of a short introductory and five parts,—viz., Anatomy and Physiology of the Female Sexual Organs, Pregnancy, Labor, the Puerperal State, and Obstetric Operations. The illustrations are numerous, the descriptions clear, the language concise, and the discussion of pathological questions temperate and just. The directions regarding treatment appear sound, but possibly might be made more explicit and positive by one favored with thirty-four years' experience in general practice and a veteran medical teacher. The chapter on Deformities (improperly called Anomalies) of the Pelvis is contributed by Dr. Henry Morris, Demonstrator of Obstetrics in the Jefferson Medical College. As this is not a System of Obstetrics, the interpolation of the work of another interrupts the continuity of the book and implies an incapacity in the author which does not exist. This is not a criticism upon Dr. Morris's contribution, which appears well done, but a plea for the organic unity of a text-book bearing the name of a well-known teacher upon its title-page. As Dr. Parvin is nothing if not classical, we feel that we must notice the use of the word "pubis" in place of "os pubis," while the comparison of the multitude of spermatozoa which, in conception, surround the ovum to the crowd of Penelope's suitors is at least in questionable taste. However, these are trifling criticisms. The author has succeeded in presenting in convenient form for reference the present aspect of obstetrical art, and the work will not only be eagerly sought for by his students, but also will prove acceptable to others who know his studious nature and appreciate his scholarly writings.

A HAND-BOOK OF MATERIA MEDICA, PHARMACY, AND THERAPEUTICS. Including the Physiological Action of Drugs, the Special Therapeutics of Disease, Official and Extemporaneous Pharmacy, and Minute Directions for Prescription-Writing. By SAMUEL O. L. POTTER, M.A., M.D. Philadelphia, P. Blakiston & Co., 1887.

This is the best hand-book on the subject of Materia Medica and Therapeutics for an American medical student with which we are acquainted. In addition to these it has chapters on Pharmacy and Prescription-Writing, and a comprehensive appendix, which contains, among other interesting subjects, Obstetrical Memoranda, the Treatment of Poisoning, and Clinical Examination of the Urine. We think that the departure from the Pharmacopœia in substituting the word "official" for the proper title "officinal," as applied to approved drugs, is unwarranted. A process might be termed official with perfect propriety, but how can a drug become official? On the contrary, if approved by the Committee of Revision, it can be ordered to be kept in the shops for the use of the profession, and hence becomes properly officinal.

THE PRINCIPLES AND PRACTICE OF OPERATIVE SURGERY. By STEPHEN SMITH, A.M., M.D. A New and Thoroughly Revised Edition. Illustrated with One Thousand and Five Wood-Cuts. Philadelphia, Lea Brothers & Co., 1887.

Since the first edition of this work appeared in 1879, eight large issues were made without any change being made in the text, although each was designated as an edition. The advances in operative surgery since the work was written necessitated almost complete rewriting of the work from the stand-point of aseptic surgery. A valuable introductory chapter on the principles discusses very appropriately the civil obligations of the surgeon, and due emphasis is laid upon the fact that antisepsis imposes new obligations. "It is of

the utmost concern to every surgeon to become thoroughly familiar with the principles and practice of antiseptic surgery." The book is freely illustrated.

NEW REMEDIES AND CLINICAL NOTES.

Embolic Obstruction of the Superior Mesenteric Artery.—An interesting case of this is reported by M. Laveran in the *Archives de Médecine et de Pharmacie Militaires* for March. The patient was first thought to have gastritis; then (on account of the severe abdominal pain and vomiting of matters containing blood) acute gastritis due to poisoning or strangulation of the bowel. Cancer came in for a share of the credit, and it was not until the autopsy had been made that the real cause of the trouble was determined.

The patient, æt. 41, entered the hospital on the 29th of October with scarlet fever, and was sent away cured on the 19th of November. The fever had been severe, but had completely subsided by the 4th of November. There had been angina, and the eruption was thoroughly characteristic. On the 14th of January the patient returned to the hospital with excruciating abdominal pains and uncontrollable vomiting. This time there was no fever, the pulse was small and frequent, and there was intense anxiety portrayed in the countenance. The abdomen was excessively painful upon pressure, especially in the epigastric region; slightly tense, but not swollen; constipation for three days; death on the 16th of January. The autopsy revealed a vegetative inflammation of the ascending aorta, the probable source of the embolus, and a sequel of the scarlet fever.

Eucalyptol for Phthisis.—M. Ball, in a communication to the French Academy of Medicine, stated that he had been testing at the Lænnec Hospital Dr. Roussel's method of treating pulmonary phthisis by eucalyptol. While his experience was not yet sufficiently extensive to warrant any positive conclusions, it had nevertheless presented him with the most gratifying results. Out of twenty-one cases, ten had been able to leave the hospital and to return to their usual occupations, six had died, and five were still within the wards. Among the latter, one case had ceased to show any bacilli in the matter expectorated six months after the beginning of the treatment, though before that time they were found there in great abundance. Cessation of the night-sweats and of the diarrhœa, and diminution of the expectoration and of the fever, were some of the immediate results of the use of eucalyptol. In one case only did the remedy have to be stopped during the course of the treatment, and this was on account of some gastric disturbance. Dr. Roussel used for the hypodermic injection one gramme of a fluid consisting of one part of eucalyptol to four parts of pure olive oil. The injections are made in the region of the hip.

Trachoma of the Vulva.—Under the term "trachoma pudendi," Dr. Tarnowski, of Russia, classifies an affection of the vulva which has for its special characteristics eruption and itching. He sees in it a perfect analogy with the classical trachoma, or chronic granular conjunctivitis. It frequently follows gonorrhœa, a fact which harmonizes well with the well-known notion of the gonorrhœal origin of the ocular trachoma. The skin is roughened, which, according to the microscope, is covered with epithelial papillomata, with the horny layer prominently developed and containing a mass of micro-organisms seated within the epithelium and adenoid tissue. These organisms penetrate deeply into the papillomatous tissue, and are surrounded by a peculiar membrane. The itching is particularly characteristic of this affection, and, instead of scratching, the patients show a tendency to press the parts by pressing the thighs together. The application of cold will cause the itching to cease. Scarification and the use of caustics are the most successful in the treatment of this annoying eruption.

Malarial Orchitis.—The report of a case of orchitis due to marsh-poison appears in the *Archives de Médecine et de Pharmacie Militaires* for March. The patient, æt. about 23, a soldier of Tunis, suffered an attack of malarial fever two years after the first malarial seizure. On the second day of the fever, which was of the quotidian type, a rapid inflammation began in the right testicle. Under the steady employment of quinine the fever and orchitis had subsided almost entirely by the fifth day, and the patient was well on his way to convalescence. On the ninth day the fever, as well as the orchitis, suddenly broke out again, but this time the latter was on the left side. On the thirty-third day the patient left the hospital cured, with his testicles half their original size and still undergoing progressive atrophy.

The Causative Element in Uterine Fibromata.—Again the ubiquitous microbe has come to play, in an entirely new *rôle*. He has been sought for in almost every nook and cranny of the human frame, and usually some one has been able to find him there, but this time he is met with as the happy occupant and *causa prima* of all uterine fibroids and ovarian cysts, according to a curious and unexpected communication sent to the Société de Biologie by Drs. V. Gallippe and L. Landouzy. They believe that they

have discovered a parasite which by its irritant action upon the tissue-elements causes the growth of these tumors. The experiments of these gentlemen were not sufficiently guarded against every possible source of error, nor were they performed as crucial tests sufficiently upon normal tissues and other tumors in a way to force us to adopt their conclusions as incontrovertible.

Pure Distilled Water for Tests and Hypodermic Solutions.—M. Lacour recommends passing a current of steam through the worm of the distilling apparatus for about ten minutes before beginning the distillation of water to be used afterwards in delicate tests. In a number of trials without this precaution he invariably found traces of organic matter in the distilled water. The worm of the still when not in use offers most favorable conditions for the development of colonies of many forms of low organized life. This simple precaution has been effectual in reducing to a minimum the organic matter which sometimes finds its way into the distilled water, and which has caused considerable embarrassment sometimes in making exact tests.

Corneal Ulcers.—In corneal ulceration, according to Dr. A. E. Prince, of Jacksonville, Illinois, the questions to-day are not whether it is phagedenic, crescentic, rodent, or asthenic, or whether the abscess be hypopyon or not, but we ask, Is it septic? Where is the source of the infection? What is the nature of the micro-organism? and What will destroy it? Empirical methods, which have been most successful, are now explained by their antiseptic effects. The actual cautery, recommended in 1873 by Martinachi, has steadily gained in favor. In 1885, Dr. A. Needen reported his first hundred cases treated by the galvano-cautery without a single failure to arrest the destruction and save the eye. A collyrium of atropine is useful in addition where peripheral perforation exists or is threatened (strength, gr. j–ij to the ounce, preferably in $\frac{1}{1000}$ bichloride solution), or Panas' solution (biniodide of mercury gr. $\frac{3}{4}$, alcohol f$\overline{3}$v, water two pints). At the commencement of the treatment the application of a small bag of flaxseed frequently dipped in very hot water is to be recommended for the relief of pain. An ointment of iodoform (two per cent. with vaseline) will be found very grateful, and when the acute stage is past, yellow oxide of mercury (one-half to two per cent.) ointment may be used at night. Constitutional and hygienic measures are also of primary importance. — *Peoria Medical Monthly.*

Tetanus cured by Hypodermic Injections of Cocaine. — The following case came under the observation of Dr. Manuel Lopez (*El Genio Médico-Quirúrgico*):

A laborer, æt. 50 years, of nervous temperament, complained of rheumatic pains and applied for relief. He was ordered to take citrate of magnesia and rubbing, to be followed by oil and a poultice of onions to induce sweating. After one week the condition of the man was very grave. He presented opisthotonos, general rigor, frequent spasmodic attacks, and most painful muscular contractions. His face was pale, and showed evidences of great suffering; his pulse weak, frequent, and irregular; respirations were anxious and short, owing to the inability to expand the chest; intellectual faculties preserved. This was regarded as an idiopathic case of tetanus, owing to the absence of any lesion to which the origin of the disease might be traced.

Chloral was administered, and anodynes applied to the vertebral column and limbs. On the third day he was compelled to suspend the administration of chloral, on account of the difficulty experienced in taking it. In place of this, three injections of five-per-cent. solutions of hydrochlorate of morphine and cocaine in equal parts were made in ten separate places on the body and limbs. Two hours after, the invalid was able to flex the limbs, turn in bed, and open the mouth; the painful contractions had ceased. Continued improvement enabled him, at the end of one week, to return to his occupation.—*La Crónica Médico-Quirúrgica.*

Uterine Hemorrhage.—Hydrastis Canadensis, given in the form of twenty minims of the fluid extract three or four times daily, has been found to check uterine hemorrhage effectively in cases of fibromyomata, subinvolution, and hemorrhagic endometritis, by R. W. Wilcox, M.D., who has also used it in climacteric hemorrhage with success. In many cases it appears to obviate the necessity of recourse to operation.—*New York Medical Journal.*

MISCELLANY.

International Congress.—The Committee on Arrangements announce reductions to members of the Congress and their families, as follows: Cunard Line, ten per cent. deduction; Red Star Line, for round trip (Antwerp and New York) tickets, $100; Inman Line, Liverpool, round trip, $100; Hamburg Line, $90; Royal Netherlands, Amsterdam, $85; North German Lloyd, $87.50. Important deductions are also made in the rates of Washington hotels.

Professor George E. Post, of the Syrian Protestant College, Beyrout, Syria, will attend the International Medical Congress.

Dr. William Goodell will remove on June 1 to No. 1418 Spruce Street.

INTERNATIONAL CONGRESS.—Jeffrey A. Marsten, R.A., Deputy Surgeon-General, has been appointed by the Horse Guards to represent the Medical Corps of the British Army at the International Medical Congress at Washington in September next.

The Admiralty has likewise commissioned Deputy Inspector-General Lloyd, R.N., to represent the Medical Department of the British Navy on the same occasion.

THE UNIVERSITY OF PENNSYLVANIA.—On the 2d inst., the Medical Department held its Annual Commencement, graduating one hundred doctors in medicine. Provost William Pepper, M.D., conferred the degrees. The Valedictory Address was delivered by Dr. William Goodell, Professor of Clinical Gynæcology. The annual dinner of the Alumni Association was given to one hundred and fifty graduates in the chapel of the University. Dr. R. A. Cleemann presided.

THE Fourth Annual Meeting of the American Climatological Association will be held in Baltimore, Tuesday and Wednesday, May 31 and June 1, 1887, in the hall of the new Physical Laboratory of Johns Hopkins University, Monument Street, near Eutaw.

OFFICIAL LIST

OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U.S. ARMY FROM MAY 8, 1887, TO MAY 21, 1887.

LIEUTENANT-COLONEL C. T. ALEXANDER, SURGEON.—Granted leave of absence for four months, with permission to go beyond sea, to take effect May 23, 1887.

CAPTAIN P. F. HARVEY, ASSISTANT-SURGEON.—Granted leave of absence for four months, with permission to go beyond sea, to take effect June 10, 1887. S. O. 105, A. G. O., May 7, 1887.

MAJOR MORSE K. TAYLOR, SURGEON.—Retired from active service, May 14, 1887. S. O. 111, A. G. O., May 14, 1887.

R. H. WHITE.—Promoted to be Surgeon, with the rank of Major, to take effect from May 14, 1887.

CAPTAIN VICTOR BIART, ASSISTANT-SURGEON.—Ordered for examination by Army Retiring Board at Fort Leavenworth, Kansas. S. O. 107, A. G. O., May 10, 1887.

CAPTAIN F. W. ELBREY, ASSISTANT-SURGEON.—Ordered for examination by Army Retiring Board at Washington, D.C. S. O. 109, A. G. O., May 12, 1887.

CAPTAIN JOHN D. HALL, ASSISTANT-SURGEON.—Granted leave of absence for one month, with permission to apply for one month's extension. S. O. 74, Department of Colorado, May 11, 1887.

WILLIAM N. SUTER.—Appointed Assistant-Surgeon, U.S. Army, with the rank of First-Lieutenant, to rank as such from May 16, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U.S. NAVY FOR THE TWO WEEKS ENDING MAY 21, 1887.

SURGEON C. U. GRAVATT.—Detached from the U.S.S. "Michigan."

PASSED ASSISTANT-SURGEON G. P. LUMSDEN.—Ordered to the U.S.S. "Michigan."

PASSED ASSISTANT-SURGEON RICHARD ASHBRIDGE.—Detached from the Naval Academy, and to the Practice-Ship "Constellation."

PASSED ASSISTANT-SURGEON THOMAS H. STREETS.—Promoted to Surgeon.

PASSED ASSISTANT-SURGEON L. W. CURTIS.—Ordered to the "Quinnebaug."

PASSED ASSISTANT-SURGEON J. W. BAKER.—Ordered to the Hospital, Chelsea, Massachusetts.

SURGEON A. F. PRICE.—Ordered to Board duty, Annapolis, Maryland.

SURGEON C. U. GRAVATT.—Detachment from the "Michigan" revoked.

PASSED ASSISTANT-SURGEON G. P. LUMSDEN.—Orders to the "Michigan" revoked.

SURGEON C. A. SIEGFRIED.—Ordered to the "Quinnebaug."

SURGEON R. C. PERSONS.—Detached from the "Saratoga."

SURGEON W. G. FARWELL.—Ordered to the "Saratoga."

SURGEON W. S. DIXON.—Ordered to special duty, Baltimore, Maryland.

SURGEON R. F. ROGERS.—Ordered to the Marine Rendezvous, New York.

PASSED ASSISTANT-SURGEON HOWARD WELLS.—Ordered to the "Jamestown."

SURGEON J. C. WISE.—Detached from the "Jamestown."

SURGEON H. P. HARVEY.—Ordered to the "Iroquois."

SURGEON J. R. WAGGENER.—Detached from the "Iroquois."

DR. S. STUART WHITE (of Frederick, Maryland).—Commissioned Assistant-Surgeon in the Navy, May 19.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U.S. MARINE HOSPITAL SERVICE FOR THE SIX WEEKS ENDING MAY 21, 1887.

GOLDSBOROUGH, C. B., SURGEON.—Leave of absence extended thirty days, on account of sickness, April 20, 1887.

DEVAN, S. C., PASSED ASSISTANT-SURGEON.—Granted leave of absence for thirty days, to take effect when relieved, April 12, 1887.

BRATTON, W. D., ASSISTANT-SURGEON.—To proceed to Port Townsend, Washington Territory, and assume temporary charge of the service, April 21, 1887.

FESSENDEN, C. S. D., SURGEON.—Detailed as chairman of Board for physical examination of cadets, Revenue Marine Service, May 13, 1887.

STONER, G. W., SURGEON.—To proceed to Delaware Breakwater as Inspector, and to New York and Philadelphia, to inspect unserviceable property, May 12, 1887.

IRWIN, FAIRFAX, PASSED ASSISTANT-SURGEON.—Detailed as recorder of Board for physical examination of cadets, Revenue Marine Service, May 13, 1887.

FATTIE, J. B., ASSISTANT-SURGEON.—Relieved from duty at Baltimore, Maryland; ordered to Marine Hospital, St. Louis, Missouri, May 13, 1887.

GOLDSBOROUGH, C. B., SURGEON.—Leave of absence extended to June 1, on account of sickness, May 18, 1887.

GUITÉRAS, JOHN, PASSED ASSISTANT-SURGEON.—Granted leave of absence for four days, May 21, 1887.

ARMSTRONG, S. T., PASSED ASSISTANT-SURGEON.—To remain in charge of service at Memphis, Tennessee, until further orders, May 21, 1887.

DEVAN, S. C., PASSED ASSISTANT-SURGEON.—Leave of absence extended thirty days, May 19, 1887.

HARRINGTON, P. M., ASSISTANT-SURGEON.—Ordered to U.S. Revenue Steamer "Rush," May 18, 1887.

NORMAN, SEATON, ASSISTANT-SURGEON.—To proceed to Marine Hospital, Baltimore, Maryland, for temporary duty, May 20, 1887.

HEATH, F. C., ASSISTANT-SURGEON.—Granted leave of absence for thirty days, May 18, 1887.

WOODWARD, R. M., ASSISTANT-SURGEON.—Appointed an Assistant-Surgeon May 20, 1887. Assigned to temporary duty at the Marine Hospital, Baltimore, Maryland, May 21, 1887.

PHILADELPHIA, JUNE 11, 1887.

ORIGINAL LECTURES.

CLINICAL LECTURE

ON CASES ILLUSTRATING THE TREATMENT OF HEMORRHOIDS, FISSURE OF THE ANUS, AND CARCINOMA OF THE RECTUM.

BY A. G. GERSTER, M.D.,
Professor of Surgery in the New York Polyclinic.

GENTLEMEN,—This man, 46 years of age, was operated upon several years ago for external hemorrhoids. He now complains of difficulty in micturition and pain about the anus. On examination by palpation I find a fissure, situated posteriorly, extending up to the inner margin of the external sphincter. You may ask, How do I know that there is a fissure, since I have not seen it, and have no other proof of its existence than what is told me by my finger introduced into the rectum? A fissure, especially one which is not recent, can be diagnosticated by the touch quite as well as by visual examination. The margins of the fissure are indurated, and can be distinctly felt by the finger of one whose touch is tolerably fine.

I have asked the assistant whether the patient has been examined previously because he complains of trouble with micturition. A simple examination of the anus of a nervous patient is frequently sufficient to stop the flow of urine. You know that the connection between the nerves supplying the rectum, bladder, and adjacent organs is very intimate, and that reflex irritation of the bladder at once manifests itself in many patients of a nervous disposition by irritation of the rectum. Thus, for instance, certain persons suffering with prostatic disease will also suffer with spasm of the sphincter ani; and, *vice versa*, a patient who is very sensitive, and suffers with an internal hemorrhoid located near the prostate, will complain of difficulty in micturition. By examining such a patient, stretching the sphincter, as, for instance, by the introduction of the speculum into the rectum, you may unintentionally stop urination, and it may become necessary to withdraw such a patient's urine with the catheter for ten days or two weeks after your examination.

We notice by palpation over the pubic region that the bladder is empty, and this is now confirmed by the introduction of the catheter, which withdraws very little urine.

Regarding the care of catheters I may say a few words. It has become the fashion lately to treat everything to corrosive sublimate or carbolic acid without any discrimination. This has led to a good deal of mischief, not only in the peritoneal cavity, but also in the urethra. The urethra has a very sensitive mucous membrane, and in disinfecting your instruments before introducing them into the urethra you use sometimes as high as a five-per-cent. solution of carbolic acid, or one to one thousand of corrosive sublimate. Now, these solutions are very irritant. But what does irritation mean? Irritation is an expression which may mean ten different things. The word occurs on nearly every page of old surgical works, and on nearly every page it is intended to mean something else. In fact, you can imagine almost what you please when one speaks of irritation. It may mean acute pain from a mechanical cause; it may mean any degree of inflammation, as chronic inflammation, acute inflammation, phlegmonous inflammation. Let us, then, be more precise, and define what we mean when we speak of irritation. I mean by irritation in this case that when a solution like corrosive sublimate or carbolic acid is introduced into the urethra, coming in contact with the tender epithelium, it has the effect of causing corrosion. It coagulates and kills the most superficial layer of epithelium lining the urethra. This leaves an eschar; the cells become opaque, there remains a white blotch. This is cast off, leaving a raw surface. That raw surface must, of course, give rise to a secretion. Thus the result of the introduction of an instrument into a strong solution of corrosive sublimate or carbolic acid before passing it into the urethra is a urethritis with a discharge. Sometimes there is a good deal of discharge, especially in patients upon whom catheterism has to be regularly repeated. Suppose you have a healthy patient, except that he is suffering from a fissure in ano or hemorrhoids. You make an examination or operate, and following this the patient becomes unable to pass his urine. You must

now catheterize the patient, or instruct the nurse to do it, three, four, or six times a day. You are required to be very careful in all your steps; you are on the modern antiseptic racket, to use a not very elegant but an expressive phrase, so you keep your catheter in one of these strong antiseptic solutions, and when the time comes to withdraw the patient's urine you take your catheter out of that solution and introduce it into the patient's urethra and bladder. About the third day the man complains that catheterism is painful. Your manipulations had not been painful at all in the beginning, but now they have become very painful. At your next visit he shows you his penis, and says, "Doctor, I think I have the clap," and he is astonished, and wonders where he got it. He has simply an acute inflammation of the urethra, which you have caused by an unwise application of an advanced principle in modern antiseptic surgery. The best thing can be turned into mischief by lack of judgment in carrying it out. Therefore, whenever you introduce an instrument into the urethra which has been disinfected in a strong solution of any kind, you should always first free that instrument from the corrosive substance by flushing it with hot water. After that, if you introduce it into the bladder it will not harm the patient.

Before introducing the catheter we must have the patient assume the proper position. He should place the heels together, flex the legs and thighs, and spread the knees apart. That gives the greatest amount of relaxation. Now you grasp the glans penis and introduce the instrument into the meatus, using at no time during its passage any degree of force. Hold the handle of the instrument parallel with the longitudinal axis of the body, and push it very gently forward, pulling the penis over it, just as you would pull your glove over your index-finger. Continue this until the instrument ceases to go forward with very gentle pressure. Now if you place the index-finger of your right hand on the perineum you will feel the end of the instrument below the symphysis pubis. It is important to pass around this point without exerting any undue pressure. Having got thus far, you take hold of the handle of the instrument and gently depress it between the thighs of the patient, and it will slip into the bladder without any pressure on your part. Catheterism, if carried out properly, should never be followed by hemorrhage. One drop of blood making its appearance after you remove your sound or catheter indicates that you have not passed the instrument in a skilful manner,—that you have used too much force.

While the instrument is in the bladder you can very readily ascertain the size of the prostate gland. The catheter serves as a guide in ascertaining its exact location and size.

Now, in trying to ascertain the relations of the prostate in this case I have come upon something which none of us need to have suspected. It is something which explains his whole trouble,—the presence of the hemorrhoids, of the fissure, and also the difficulty with his bladder. There is just above the prostate and behind it, at a point which I can just reach with the tip of my index-finger, a pathological change encircling about two-thirds of the gut; a crescent-shaped indurated mass, constricting the rectum so that the end of my index-finger will only comfortably pass through it. It is situated more to the right side of the patient, is apparently attached to the prostate; the mucous membrane of the rectum is still movable over it. It is apparently a growth taking its origin from the mucous membrane, but not from its surface. It is not an epithelioma in the ordinary acceptation of the term. You will remember that there is epithelioma of the rectum just as there is epithelioma of the face or tongue,—that is, a cancerous new growth which takes its origin from the epithelial covering of the surface of the parts. This seems to me to be rather an adeno-carcinoma, if you wish to accept that term, the greatest part of which consists of epithelial elements. The disease probably started in one of the muciparous glands which occupy the interior of the mucous tissue of the rectum, and, therefore, has not ulcerated, as epithelioma is apt to do very soon, on account of the macerating effect of the moisture in the rectum in which it is constantly bathed. An epithelioma of the tongue is an ulcer from the beginning, because of maceration of the surface of the epithelioma from the presence of saliva, which keeps the horny epithelial matter of the diseased portion washed away. The same thing occurs in the rectum when the epithelioma begins on the surface of the mucous lining.

This man is forty-six years of age, about the age when carcinoma is most common. He has lately lost a great deal in flesh. It is probable, therefore, that this adeno-carcinoma will go on increasing in size and thickness. In fact, everything about the case points to rather an unfavorable prognosis.

When there is a new growth, rapidly increasing in size, located near the neck of the bladder, it does not necessarily involve the prostate nor the interior of the bladder, although bladder-symptoms may be present. It is sufficient if it be near enough to irritate the nerve-filaments which go to the neck of the bladder.

This case, gentlemen, is a very interesting and a very important one. It is not alone interesting from the fact that we have successively discovered conditions any one of which seemed sufficient to explain his symptoms, but which at first thought would seem to have no connection the one with the other. The lesson which I wish to draw from the case is one which does not belong especially in the pale of surgical teaching, yet it is of the utmost importance to the success of the surgeon. Never let a patient with rectal symptoms go away from your office without giving him a thorough examination,—without making all you can of that first examination. At least do not let him go away with your opinion of the case unless you have made the necessary examination of all the parts. If I had told this man that he had hemorrhoids alone, which was all that I discovered on external inspection, I should have been far from the truth. I should have stated the truth in saying that he had hemorrhoids, but not the whole truth, and certainly not the essential part of the truth: that would have remained a mystery. Examining further, I found a fissure in ano. But that was not all. Going still further, and examining the bladder and prostate, something was felt high up in the rectum which at once threw light on the whole of the complex symptoms of which he complained, giving us a clear insight into the case and enabling us to make an intelligent diagnosis and to decide what we can do and what we cannot do for the patient. If we had treated this man for hemorrhoids alone, we would have expected a cure and would have been disappointed. By and by we would have found the fissure, would have cut it; yet the patient would have come back to us in a worse rather than in a better condition. He would have become cachectic. A colored discharge would have appeared at the anus. Then some person would have put his finger inside and found an ulcerated tumor of the rectum. Of course the reflection would have fallen back upon the first physician who had treated the case for months without having approached a correct diagnosis of the man's condition. Yet, gentlemen, this sort of practice is not uncommon. It is seen in the treatment of rectal troubles the same as in the treatment of urethral troubles. You know that sometimes a patient comes into a physician's office and says he has a clap, and the doctor does not even look at him, but gives him a prescription and tells him what to do. He thus treats the patient weeks and months, and the patient all that time is expecting a good result. Of course, if the patient has happened to hit upon a correct diagnosis of his case the doctor's treatment may prove of some benefit to him. But never rely upon the statement of the patient or upon a superficial examination which you yourself make in giving an opinion about an organ like the rectum or the urethra.

HEMORRHOIDS.

We will now examine a patient with hemorrhoids, treated by Dr. Wyeth by injecting the tumors with a mixture containing carbolic acid. I believe that a moderate degree of hemorrhoidal trouble can be treated successfully by carbolic acid injection. The objection raised to this method is that it sometimes causes extensive sloughing, not only of the hemorrhoidal node, but of a large portion of the mucous membrane of the rectum. A case occurring in New York was reported, I believe in the *Medical Record*, in which four inches of the rectal mucous membrane came away after a single injection of a hemorrhoidal node with carbolic acid. In some cases phlebitis, etc., have resulted, placing the patient in great danger. But my personal experience with this method is limited to only one case. I have not employed it oftener because most of the cases which come under my care are either light cases, not calling for any operation, or grave cases in which I prefer to give positive and permanent relief by resorting to the operation which you have seen me perform repeatedly at the hospital. I mean

the use of either the ligature or the actual cautery and clamp.

Mild cases of hemorrhoids, or those in the incipient stage, I frequently see get well without any operation at all. I have my share of such cases, and I rarely operate upon them. But I take the trouble to examine the patient carefully from head to foot, to learn all that I may about his internal economy. First, I examine for large masses of fecal matter hoarded up in the gut. This is a very ordinary condition of things in a man of sedentary habits who is over-fed and does not take sufficient exercise. Nearly all persons who suffer from hemorrhoids belong to this class. On examining them carefully you will find the large gut filled with fecal matter. But they may assure you that they are as regular as clock-work; they have a motion of the bowels every morning; and sufficient, they think. Apparently it is sufficient. But if you examine the rectum of such persons, as we often have opportunity to do very thoroughly at the post-mortem table after they have died of some pulmonary or other disease, you will find an extraordinary condition of things. The rectum and colon, as you know, are provided with a number of lateral pouches of greater or less depth. In such patients you will find these pouches filled with fecal matter. It differs in color, as well as in consistency, from ordinary fecal matter; it is harder, and of a slaty color. The evacuations which these patients have take place only through the middle of the gut, and more and more of the fecal matter becomes deposited on the walls. Imagine an old sewer being filled up in that manner, and you can form some idea of the interior of these people. As the channel becomes narrower and narrower from successive deposits of fecal matter along the walls of the gut, the patients suffer more and more, the descending colon and rectum feel like a hard bologna sausage; if you press upon it with your fingers the indentation remains, as if a mould were made of clay. Now, give this patient a good dose of calomel and salts, causing his bowels to move freely, and then examine him, and you will often still find a large quantity of fæces distending the intestine. But after once thoroughly cleansing out your patient he will not need an operation for the hemorrhoids. You will have done what a learned, sensible physician should do. You will not have treated the hemorrhoids as the pile-doctor does, whose vision does not extend beyond the internal sphincter; but you will have treated them as does the modern intelligent physician, whose vision takes in the entire patient. You will have cleaned out the Augean stables and have done the man a real service.

Look upon another patient, a fat man, one whose skin is pale, who appears to have no blood. Examine him, and you find that he has an enlarged liver. You question him, and you find that he has been drinking more beer than is good for him. Now, if such a man has internal hemorrhoids, would it be rational simply to treat those hemorrhoids? He looks like a vigorous man, but you find that after ascending a few steps to enter your office he is out of breath and is glad to sit down and rest himself. He has come to be treated for hemorrhoids, but on further examination you find not only enlargement of the liver, but also disease of the heart. There is obstruction to the whole portal circulation. Of course the hemorrhoidal veins are overfilled. Would it be rational for the physician to treat such a patient simply for hemorrhoids? Of course not. If he did so treat him, his diploma should be taken from him. The heart-disease ought to be treated, and, if successfully, the hemorrhoids will disappear. I have given these examples to show that hemorrhoids in the incipient stage do not require surgical treatment. Topical treatment will, of course, make it easier for you to effect a cure, and it will satisfy the patient. He will feel that something is being done for his piles. He could not understand that you were benefiting a diseased condition in his rectum by treating his heart alone. He is a layman; he cannot see through the whole case. A good many doctors cannot. Therefore, give him some application for the anus. Let him put an ice-bag there, or a salve, or use an astringent injection.

But when you have to deal with a hemorrhoidal condition of an aggravated character, where considerable pathological change has taken place, where there is considerable infiltration and hypertrophy and prolapsus of the mucous membrane surrounding the hemorrhoidal nodes, where they have become ulcerated and reached that stage when they cannot shrink and return to a normal state, then

an operation is necessary; and in that case I think it is better to burn them away, or to ligate them. But there is weighty authority for the local use of carbolic acid: such men as Weir, Lange, and Wyeth, in this city, employ it with good results.

ORIGINAL COMMUNICATIONS.

CASES OF EXPLORATORY LAPAROTOMY FOLLOWED BY APPROPRIATE REMEDIAL OPERATION.

CASE I.—PERITYPHLITIC ABSCESS; AMPUTATION OF THE VERMIFORM APPENDIX; RECOVERY.

CASE II.—RUPTURE OF CYST IN TUBAL PREGNANCY; INTERNAL HEMORRHAGE; DEATH.

Read before the College of Physicians of Philadelphia, June 1, 1887,

BY FRANK WOODBURY, M.D.,

Professor of Therapeutics, Materia Medica, and Clinical Medicine in the Medico-Chirurgical College of Philadelphia, etc.

I HAVE the honor of presenting to the College this evening a private patient who five weeks ago to-day was apparently *in articulo mortis* with perityphlitic abscess. Laparotomy was promptly performed by Dr. Thomas G. Morton, the abscess evacuated, and the appendix vermiformis removed at its origin, as it was found to be the site of a large perforating ulcer. I also present the specimen taken from this patient, consisting of the vermiform appendix almost divided by an ulcer; also a portion of the omentum which was included in the abscess and removed with the appendix. Accompanying these is a small fecal or phosphatic concretion, resembling in size and general appearance a cherry-stone (which it was at first supposed to be), which evidently was the cause of the ulceration. The notes of the case are briefly as follows:

Charles M. N. K., 26 years of age, born in Philadelphia, paper-hanger by occupation, not married, of spare frame, of good habits, had always had good health except that for the last three or four years he has been subject to sudden and severe attacks of abdominal pain. These attacks came on without warning while he was in excellent health, and would completely prostrate him. The pain was of a stabbing character, and was most intense across the lower part of the abdomen, and especially around the umbilicus; it was attended by great irritability of both rectum and bladder; sometimes there would be diarrhœa, but there was always a marked increase in the quantity of water voided, the urine being red "like blood" in color. He is of the opinion that he has at times passed blood in his urine. These attacks, after lasting for a few hours, usually passed away gradually, leaving him rather weak for a short time; but he rapidly recovered, and enjoyed uninterrupted good health until the next attack came on.

I first saw him on the 20th of April, when he came to my office complaining of having taken cold. He looked haggard, skin and conjunctivæ rather sallow, tongue coated, no appetite, bowels constipated. He said that he felt miserable, and had pains in his muscles in different parts of his body. He had frequent micturition, and was passing a remarkably large quantity of pale urine. At this time he did not complain of abdominal pain. He was given fractional doses of calomel and sodium bicarbonate with pepsin, and directed to keep his room.

The urine, examined when he returned on the next day, contained a large proportion of albumen (one-fifth on boiling), and under the microscope showed many leucocytes and a few hyaline casts.

April 22. Felt nauseated during the night, and took some mustard-water to cause emesis. Bowels had been moved satisfactorily with small doses of calomel. After taking the mustard-water he vomited, but was not much relieved. During the day had great irritability of the bladder, and was much prostrated. He came to my office, but was so weak that he had to rest for an hour and take stimulants before he could go home.

April 23. Spent the day lying upon a lounge; now complaining of abdominal pain. He had not slept, and was very restless. Bowels not moved for two days. Repeated calomel in fractional doses (gr. $\frac{1}{10}$ every hour until five doses were taken), and ordered quinine hydrochlorate, gr. xii daily. Poultices to abdomen.

April 24. At morning visit found that during the night he suffered intensely and did not sleep at all. Bowels not yet moved. Ordered a cupful of hot water every hour to assist the action of calomel given yesterday. In the afternoon he had had several copious movements, but the pain persisted. He indicated the point of greatest tenderness about midway between the umbilicus and the middle of Poupart's ligament. A resisting mass as large as a small egg could be detected upon deep pressure in this locality, but examination caused severe pain. Morphine sulphate in half-grain doses was given every two hours, or until pain was relieved. Poultices again applied over abdomen. Temperature 103.5°, pulse 140.

April 25. Had a very bad night. Pain in tumor excruciating, swelling somewhat larger, very tender. Skin not discolored; tumor evi-

dently beneath the peritoneum. Passed urine which was said to contain some small blood-clots. Dr. Jas. C. Wilson saw the case in consultation. Diagnosis either intussusception or perityphlitic abscess. Ten foreign leeches were applied over the spot of tenderness, with great relief to the patient. Morphine and quinine were continued.

April 26. Skin around leech-bites inflamed, tumor more flat and very tender, apparently nearer the surface. Bowels not moved since the 24th. A pint of warm sweet oil was thrown into the colon with a long tube; this felt comforting, and later produced evacuation of the bowels.

April 27. Skin around leech-bites more swollen, injected, and tender. The right lower half of abdomen was dull on percussion, the dulness extending over the middle line from a point just above the anterior inferior spine of the ilium; external to this the percussion-note was clear. General condition poor, face pale, features pinched, beads of perspiration on forehead. It was decided, upon consultation with Dr. Wilson, that opening the abdomen would be justifiable. Dr. Morton saw him at 11 A.M. At 2 P.M. laparotomy was performed. The leech-bites were noticed to be suppurating. An ounce of whiskey was given before the ether was administered. The field of operation was cleaned with soap and water, and neighboring hair removed; the surface was again washed with ether, followed by corrosive sublimate solution (1 to 2000). The usual antiseptic precautions were observed as to instruments, and the field surrounded by towels wet with the mercuric solution. The incision was made directly over the swelling, and finding the muscles infiltrated with pus it was extended until it measured nearly ten inches; commencing just above and two inches to the right of the umbilicus, it continued obliquely downward to the pubes. The peritoneum was opened, and a free flow of pus followed, having a decidedly fecal odor; in it was found a concretion resembling a cherry-stone. The vermiform appendix was greatly swollen, and exhibited a perforating ulcer extending three-fourths around its circumference and very near to the point of origin. A silk ligature was applied close to the cæcum and at the terminal portion of the appendix, and the intervening portion, comprising almost the whole organ, was removed, together with a large portion of omentum which projected into the abscess-cavity, the walls of which were then scraped with a curette and douched with simple warm water.

Following the operation he entered upon convalescence, which was uninterrupted. He was entirely free from abdominal pain, except from distention of the bladder, requiring the use of the catheter for a week. The bowels were moved naturally on May 1, after he had yolks of two eggs in milk. The temperature fell after the operation, and did not again rise above 100°. The drainage-tube was removed piecemeal; the last portion was taken away on the 13th of May. He sat up May 11, and rapidly regained strength. He was out riding May 21. His recovery was assured by careful nursing, the administration of a small quantity of whiskey, a teaspoonful every two hours, and the use of Bovinin, and the Hoff's Extract of Malt, at first every two hours (℥ss of each); lately he has been taking it only four times a day. At present the wound is healed and he appears to be in his usual health.

Case II.—Mrs. W., æt. 37 years, German, married nine years, never pregnant, had complained of more or less pain in the abdomen for a couple of weeks early in May, but had continued at house-work,—washing, lifting tubs of water, and spending much time upon her feet. Previously she had good health, menses regular, bowels constipated usually. About the middle of the month there was obstinate constipation, upon which powders obtained from the druggist were without effect. The abdomen was then rubbed with turpentine and sweet oil at her husband's suggestion, and a large enema used, which produced a copious evacuation about eleven o'clock on May 20. Upon returning to bed, in about an hour after the bowels were evacuated, she experienced excruciating pain low down in the right side of the abdomen and around the umbilicus. She was seen by me for the first time about one o'clock A.M. May 21, when I found her lying upon her left side, with the knees drawn up, complaining that movements caused increase of pain. A tumor as large as an egg was detected in the right hypogastric region, above the middle of Poupart's ligament. It was intra-peritoneal, and not a hernia. Under the influence of deodorized tincture of opium she became more comfortable, but in the afternoon she seemed to be growing weaker, the abdomen was rather distended and uniformly tender, and her pulse was soft and rapid (140 to the minute). During the afternoon she vomited freely a watery fluid, and with it a large ascaris. Her menses had appeared on the 16th and had lasted four days, but on the 21st she had a copious flow of blood from the uterus.

Exploratory laparotomy was advised, and she was removed to the Pennsylvania Hospital, where the operation was performed at 9 P.M. Upon opening the peritoneum a large gush of blood occurred, and a small fœtus of about four weeks' development came out among the clots; it was estimated that about three pints of blood was contained in the abdominal cavity. There was a ruptured sac in the right tubo-ovarian region, the result of the arrest of an impregnated ovum near the extremity of the Fallopian tube. A silk ligature was thrown around the pedicle near the uterus, and the tube, ovary, and sac removed. A few

points of oozing were touched with the Paquelin cautery, the wound thoroughly cleansed with hot water, and a drainage-tube introduced. The patient had no pain after the operation, but did not react well. On the next evening transfusion of blood was performed (one of the resident physicians furnishing eight ounces for the purpose), but with only temporary improvement. She died from exhaustion about 2 P.M. on Tuesday, having survived the operation sixty-five hours.

The autopsy showed a wound united, except just at the point of emergence of the drainage-tube, the track of which was lined by lymph without any evidence of suppuration.

The uterus was found to be the site of a number of interstitial and sub-peritoneal fibroid tumors, and was moderately enlarged and contained some decidual membrane and blood-clots.

[In the discussion of this paper Dr. Morton reported another case of laparotomy which he performed for perityphlitic abscess, seen in consultation with Dr. Edward R. Stone, of this city, who furnished the following notes:

"Mrs. G. W. G., æt. 34, mother of one child (four years old), has been healthy, except that she was of a nervous disposition with decided hysterical tendency. The bowels were habitually constipated, and she had at various times during the last three years attacks of pain, apparently in the bowels, which readily yielded to anodynes and laxatives. It was reported that she had a severe attack of pain, with vomiting, last July, while she was out of town, which required hypodermics of morphia and confinement to bed for four days. In December last I attended her in an attack of abdominal pain which was not confined to any particular region, and which passed away in a few hours.

"On February 17, 1887, she was much on her feet, shopping, etc., and on the evening of that day she took a dose of pills to bring on the menstrual flow, which was a few days over-due. February 18 was spent in active work, washing and ironing. The pills operated on the bowels three or four times, but menstruation did not appear. She went to bed as well as usual, but about 11 P.M., February 18, she had severe pain, with vomiting of the contents of the stomach. The pain was described as darting from the right hypochondrium towards the navel. There was no tumor perceptible, nor tenderness to pressure. Counter-irritation with mustard was ordered, and one-fourth grain of morphia injected under the skin.

"February 19, 10 A.M. Morphia controlled the pain for about three hours, during which she had some sleep. She has not vomited, and the abdomen appears normal, except that she complains of some tenderness to the right of the umbilicus; temperature and pulse normal. Hypodermic injection repeated, and an anodyne mixture ordered.

"February 19, 6 P.M. Pain has not been very severe, but returns when the effect of morphia passes away; no vomiting to-day; bowels have not moved since Thursday; abdomen somewhat tympanitic, and tender to the right and above the umbilicus; tongue somewhat coated and red at tip; anorexia; temperature 100°; pulse 90. Morphia continued, and turpentine stupes, followed by poultices.

"February 20, 9 A.M. Has passed a restless night, requiring frequent doses of morphia; vomits freely a yellowish fluid, apparently from the small intestine; abdomen quite tympanitic and tender; no fæces nor flatus have passed from the rectum; expression anxious; pulse small, 110; temperature 101°. Small doses of calomel were added to the treatment, which served to check the vomiting, except when fluids were swallowed in considerable quantity. There was no abatement of the disease during the day, and Dr. Montgomery saw her in consultation in the evening, and advised an exploratory incision, which was declined.

"February 21. Symptoms continue. She was quieter and much weaker; abdomen very large and tender; tongue dry and red; vomiting easily provoked. An enema of water was administered during the night, but it brought nothing away. The operation of abdominal section, with a free incision, washing out the cavity, was performed this day.

"She did not recover from the shock, dying about 2 P.M. February 21, 1887.

"The points of interest from a medical point of view I may be allowed to emphasize:

"1. The possible relation of former attacks of abdominal pain to the ulceration of the appendix.

"2. The effect of the pills in hastening an impending perforation.

"3. The seat of pain not at all in the usual locality for disease, near the ileo-cæcal valve. The early symptoms seemed rather to indicate the passage of a gallstone.

"4. The paralytic distention of the bowel simulating an obstruction from some more active cause.

"EDWARD R. STONE."]

REPORT ON OPHTHALMOLOGY.

BY ALBERT G. HEYL, M.D.,

Ophthalmic Surgeon to the Episcopal Hospital.

PATHOLOGICAL ANATOMY OF THE EYE IN BRIGHT'S DISEASE.

THE following is a synopsis of an extremely important contribution to this subject by Dr. Carl, Archduke in Bavaria, well known for his work in ocular

pathology. The monograph is made up of a series of observations made upon sections prepared with the latest and best appliances known to the microscopist, and is especially valuable for the minute study of the ocular blood-vessels. The value of the observations has led to so extended a synopsis of this monograph.

Case I. — Boy, aged 12. Admitted February 8, 1882, in a completely unconscious state, into Professor Ziemssen's clinic. There was paresis of the right half of the body, right facial paralysis, left-sided cardiac hypertrophy, arterial sclerosis. Examination of urine showed a large amount of albumen, with some hyaline casts. Specific gravity 1003. Three weeks previous to this a double neuro-retinitis albuminurica had been observed. Symptoms of acute pneumonia occurred, which resulted in death. Post-mortem showed the right kidney enormously diminished in size; cortical substance markedly pigmented and diminished in area. Left kidney ten centimetres long, five centimetres broad, three centimetres thick; cortical substance diminished in area and characterized by disseminated points of pus of the size of a pin-head. Atheroma of the cerebral arteries. Apoplexies in both hemispheres. Perforating ulcer in duodenum, with consequent peritonitis.

The microscopic examination of the eyes showed the following changes in the retinal vessels: 1. An arterial vessel, cut somewhat obliquely in making the section, showed the lumen not materially changed, the endothelium normal, but the remaining coats not distinguishable, owing to a degenerative process. 2. On the same vessel another place was found in which the endothelium was not so distinct, and at one point no longer recognizable, as a conical, finely-granulated mass had worked its way into the lumen of the vessel; the vessel-wall is degenerated, as in the previous case, and the conical mass referred to seems to be the result of this change. 3. This molecular change in the vessel-coats seems to be generally characterized by the formation of round cavities or spaces, one observed suggesting very strongly an aneurismal character, but probably due to the melting of two or three spaces into one. 4. In one preparation the endothelium was forced into the lumen of the vessel by these cystoid spaces filled with detritus, thus diminishing the calibre of the vessel. 5. The endothelium may be completely detached. These changes were noted in the main arterial trunk arterioles, and even careful examination of the capillaries showed slight tendency to the same degeneration.

The venous vessels showed no changes beyond a very wide lumen, a slight opaqueness (verwaschen sein) of their coats, and a light grade of infiltration towards the perivascular sheaths. These changes in the arterial system exist principally in the neighborhood of the papilla. Likewise in the choroid, especially in the circumpapillary region, the same arterial changes occur, but much more pronounced than in the retina. Sections of large arteries showed the lumen either entirely absent or extremely reduced in calibre, while the vessel-walls were very much thickened. Hemorrhage into the arterial coats, as well as collections of blood-corpuscles in the perivascular sheaths, was observed. In some cases the regressive metamorphosis was so pronounced that it was difficult to tell whether a blood-vessel section was being observed, or simply a "hyaline" product. The observations on the choroidal vessels of medium calibre were specially interesting, because they confirm the view which Köster and his pupils have emphasized,—that in the so-called endarteritis obliterans the layer of vessel-wall which limits the lumen is attacked secondarily.

In the observations referred to, the endothelium was found intact, while the coats outside of it were attacked in the way already described, but careful study of the sections showed that the process started to the external side of the intima. The statement is not made that the intima and endothelium are never involved in this process, but rather that in arteritis obliterans the changes in the muscular tunic just as often induce closure of the vessel as those of the intima and endothelium, and that the primary change commences in the outer coats of the vessels. Another preparation showed the evidence of a tear in the vessel-walls. [This goes to show that the intra-ocular hemorrhages in albuminuric retinitis are not always per diapedesin.—H.] It is specially interesting to know that this arteritis is highly developed in the smallest arterioles of the choroid, and that the sections demon-

strated that the chorio-capillaris possesses a perithelial sheath; between this and the endothelial tube a lamellated mass was frequently observed, in some places showing a tendency to molecular disintegration; in others, masses of red corpuscles, some of normal appearance, others in a state of degeneration. An important question is in what tissue originate the degeneration-masses found in the vessel-coats. The observations seem to show that it is in the leucocytes, and the process may be designated as a leucocytic hyaline degeneration. The process begins with an hydropic degeneration of the leucocyte, the protoplasm loses its molecular (feinkörnig) structure, and is changed into a more or less homogeneous mass, and the nucleus degenerates. The red corpuscles can degenerate in a similar way. Not merely are, however, regressive changes found in the retina and choroid, but also production changes. New formations (neubildungen) were observed associated with destruction of the perceptive elements of the retina. Mingled with these new formations are here and there hyaline masses, which the intermixture of yellow-brown granules showed must have their origin in masses of red corpuscles. In none of the preparations from this case could the so-called sclerotic degeneration of the nerve-fibres be observed. The phenomena of arteritis obliterans already described were likewise observed in the vessels of the sclera, the corpus ciliare, the iris, and the conjunctiva. With this peculiarity, however, the complete obliteration of the vessels observed in the retinal and choroidal vessels was absent, except at the point where the scleral vessels join the choroidal system. In isolated spots in the iris thrombosis and complete closure of the vessel were observed.

Case II.—This case was a man, æt. 42, in whom a slight neuritis optici was observed several weeks previous to death. Post-mortem showed both kidneys diminished in size. Parts of the surface sunken in, with here and there a serous cyst. The microscope showed the change seen in the contracted congestion kidney (stauungs niere). The retinal changes in this case represented an early stage of the processes described in Case I. The muscular coat of the large arteries and also of the arterioles was œdematous and infiltrated with round nuclei (körnen). Also marked œdema of the retina, especially in layers in which the blood-vessels lie. In many places, through these changes in the vessel-coats the lumina of the vessels are narrowed so that a single corpuscle would barely pass, and some were not permeable at all. The thrombotic condition of the arterioles and capillaries resulting from this existed especially in the immediate neighborhood of the optic disk, and especially in the nerve-fibre ganglion cell-layer and the inner granular (körnen) layer. As the result of this, a degeneration existed in these layers which is to be looked upon as a coagulation necrosis. This necrosis was likewise observed in the external granulated (granulirte) layer. The choroidal changes were similar to those of Case I. With reference to the disputed question whether the ganglion-cells in the retina become degenerated in retinitis albuminurica, the author finds that they do.

Case III.—The clinical history of this case is unknown, beyond the fact that the specimen was taken from a case of albuminuric retinitis. The papilla, in contradistinction to the previous cases, was enormously swollen, its tissue-elements being pressed asunder by a serous infiltration. The changes in the vessel-coats, which were not limited to the vessels of any single membrane of the eye, consisted in an extensive cell-proliferation. It could not be observed that the tunica media was involved more than the other coats. As the result of this thickening the calibre of the vessels was diminished; in places the lumen was more narrowed than in others by a ring-like projection of the endothelium giving a nicked-like appearance to the vessel. This condition seemed to be more apparent in the nervous system, while in the arterial there was, as a rule, an even concentric narrowing. The cause of this thickening of the vessel-coats in addition to the above-mentioned cell-proliferation is an œdema of all the vessel-coats pressing asunder the elements.

Case IV.—Man, æt. 41. Interstitial nephritis; cardiac hypertrophy; marked albuminuria; specific gravity 1008; retinitis apoplectica et albuminurica. Death from pulmonary œdema, with lobular pneumonia. Post-mortem confirmed the diagnosis. Kidneys extremely reduced in size. The changes in the ocular sections were different from those in the last case, due, the author thinks, to their presenting

a much later stage of the disease. The thickening of the vessel-coats is generally missed, while hyaline degeneration of them is very common. Thrombi are numerous. As regards the nerve-tissue, the components of the opticus were markedly separated (zerklüftet), both in the region of the lamina cribrosa and to the retinal side of it. Numerous hemorrhages in the retina were observed.

Case V.—This was from a patient, 20 years old, with parenchymatous nephritis, cardiac hypertrophy with dilatation, marked atheroma of the brain-arteries, etc. The retinal and choroidal changes were essentially those of the previous case.

(To be continued.)

TRANSLATIONS.

Thymol for Tape-Worm.—As an excellent remedy for the expulsion of tape-worm, Dr. Numa Gampi proposes thymol or thymic acid. The physiological effects of thymol are very little known. Lewin claims for it germicide and antiseptic powers stronger than phenic acid. Bucholtz, studying its antiseptic properties comparatively, has shown it to be surpassed only by the bichloride of mercury; all the other antiseptics are inferior. Thymol does not confine its action solely to the inferior organisms. The method recommended by Dr. Gampi is as follows:

In the morning thirty grammes of sweet oil are given, and during the day eight grammes of thymol in twelve doses, to be taken one dose every fifteen minutes; twenty minutes after the last dose twenty grammes of sweet oil should be given.

During the administration of the thymol it is necessary to sustain the strength of the individual by cordial or stimulant, as cognac or rum, because the thymol exercises a depressing effect, according to the experiments of Huseman.

In *résumé*, the author recommends thymol for the following reasons:

1. It does not produce any disorder of the stomach or intestines, and its depressing action is easily controlled by the use of stimulants.

2. Its easy administration and rapidity of action, without requiring the classical three periods of preparation, expulsion, and after-treatment.

3. It is at the same time both a tæniafuge and a tæniacide.

4. In case of error of diagnosis, it will merely purge and disinfect the intestinal canal.

5. It may be supposed, from its action upon tænia which resisted all other remedies, that it would give very good results in the removal of any other worms that may be present.

6. Having given at all times the same unvarying result, the author thinks that we have at last in thymol a genuine specific for tænia.—*Il Racogglitore Medico.*

The Jugulation of Typhoid Fever by Quinine and Warm Baths.—In an extended paper in the *Bulletin Général de Thérapeutique*, Dr. G. Pécholier reports eleven cases of typhoid pursuing a uniformly favorable course, making sixty-five cases treated by the same method without a single failure. He concludes that by its antizymotic action quinine associated with warm baths shortens or aborts typhoid fever, cases usually terminating in convalescence on the fourteenth or sixteenth day.

Infantile Diarrhœa.—Hayem has found that the green color of the discharges from the bowels of infants suffering with entero-colitis is caused by a microbe which secretes this green coloring-material. The disease is epidemic and contagious. The best manner of treating it is to give to the child a dessertspoonful of a two-per-cent. solution of lactic acid after each time of nursing.—*La France Médicale.*

Treatment of Tuberculous Laryngitis by the Curette.—M. Gouguenheim, in the name of M. Hering, of Warsaw, read a note of cases of tuberculous ulceration of the larynx treated by scraping. Twenty-eight cases were treated, which were divided into three classes. In the first category were nine cases of laryngeal and pulmonary phthisis; duration of cicatrization from three months to a year, without return. In the second there were, of cases of return after cicatrization, three cured. In the third there were six cases of ulceration of the nose, of the pharynx, and of the tongue, with a bad general condition; but still in two cases cicatrization occurred, which persisted until death.

PHILADELPHIA, JUNE 11, 1887.

EDITORIAL.

THE HEREDITY OF TUBERCULOSIS.

NOW that the parasitic origin and the contagiousness of tuberculosis have become matters of demonstration, the question of the heredity of this disease enters upon a new phase. It is among the benefits of progress in science that questions unsettled by old methods of study may at least be reinvestigated by new methods. For the invention of the method goes before the discovery of the fact, and every approach to an unsolved problem by a new way tends to hasten its final solution.

That the children of consumptives frequently become tuberculous is incontestable. But how? Do they bring with them into the world the germ transmitted by their parents, or do they simply inherit a special morbid aptitude, which, acting as a predisposing cause, renders them peculiarly prone to the exciting cause, the contagion to which they are in a high degree exposed by their necessary association with their invalid parents?

Firket, of Liege, who has recently investigated this question in the light of existing theories, although unwilling to formulate positive conclusions in the present state of knowledge, regards the following propositions as tenable:

1. The transmission of a disease from the mother to the fœtus by way of the placenta occurs only when there is an infection of the blood, as in such maladies as anthrax, relapsing fever, and (probably) variola and syphilis.

2. In primary chronic pulmonary tuberculosis (pulmonary phthisis) the anatomical signs of parasitic blood-infection are absent in more than half the cases. When this infection is observed it advances by degrees, little by little, in a manner wholly different from the infection of charbon. Complete infection corresponds to acute miliary tuberculosis.

3. Congenital tuberculous infection by way of the placenta must be regarded as possible, and seems to explain certain cases of congenital tuberculosis primarily developed elsewhere than in the lungs. The frequency of this condition needs to be investigated. But congenital tuberculosis has no special predilection for the lungs, and the fact that these organs are the seat of predilection for primary tuberculosis appears to prove that primary pulmonary tuberculosis is not ordinarily due to congenital infection by means of the blood from the placenta.

A CONGRESS OF CREMATIONISTS.

THE rest of mankind, who are disposed in an uneasy way to jest at undertakers, affect to be amused at the annual conventions of the Association of "Funeral Directors." This affectation of levity, which at best is forced, must vanish upon the announcement in the journals of an International Congress of Delegates from the Societies and Friends of Cremation to be held at Milan next September. The disposal of the dead in such a manner as will do no violence to the prejudices or the health of the living has become in the great centres of population an urgent problem. In so far as funeral directors' conventions tend to the diffusion of useful knowledge relating to the care and preservation of corpses, the prevention of contagion, and the decent ordering of funerals, they serve a useful purpose. Nor would we discourage the social aspect of these gatherings, the transient relaxation from habitual perfunctory professional sadness of manner, or some banqueting and

general good-fellowship. But we protest against all combinations to magnify the pomp and circumstance of obsequies, and to raise the cost of dying, which is one of the prime necessities of life.

The Milan Congress will doubtless lead to practical results in stimulating inquiry and diffusing information in regard to the subject of the disposal of the dead even among those who are opposed to cremation; it will reawaken an interest in cremation, which appears just now, especially among the English-speaking races, to be flagging; but its chief work will be among those already interested in and committed to cremation itself. That it will exert any influence in allaying ecclesiastical opposition is not probable, nor does it seem likely that the medico-legal objections to this method will be fully met. Yet, as it will consist largely of men of science from various points, and as its scope includes the hygiene of cemeteries, it is to be hoped that much good work will be accomplished.

The programme includes reports on the progress of cremation among the different nations, a plan for an international league among the cremation societies, proposed international legislation in the matter of the transportation of cadavers from one country to another, and in regard to their incineration and the preservation of the ashes, from the stand-point of public hygiene and legal medicine, and, finally, the consideration of the different systems of cremation in their technical, moral, hygienic, and economic aspects. There will also be held, in connection with the Congress, an exhibition of models, plans, machinery, instruments, apparel, books, laws, and other matters illustrating the subject in its historical and its present aspects.

SPERMACETI, FATTY ACIDS, AND SOAPS AS DIETETIC AGENTS.

MANY persons have an unconquerable repugnance to cod-liver oil and other fats used as food in wasting diseases. Others fail to digest fat properly, and hence in many cases digestive disturbances result when the administration of fat is attempted.

In normal fat-digestion these substances are decomposed into the fat-acids and glycerin, and the liberated acids combine with the alkalies with which they come in contact in the intestinal canal and form soluble soaps, which are easily absorbed.

The researches of Immanuel Munk have shown that the fatty acids alone are competent to produce the nutritive effect of fat, and that the glycerin with which they are in combination is not only unnecessary, but sometimes injurious.

Bearing these physiological facts in mind, Professor Senator has studied the effects of spermaceti, pure fatty acids, and soaps as substitutes for cod-liver oil and other fats in the treatment of cases characterized by deficiency of fat or rapid wasting of tissue.

According to Senator, spermaceti was formerly much used as an internal medicament in coughs and other irritable conditions of the throat, especially in children. He uses it, however, frequently as a substitute for cod-liver oil. When finely pulverized and mixed with sugar and flavored with some essential oil, as oil of lemon, it can be taken in teaspoonful-doses without producing any nausea. It is, in fact, quite palatable. Two and a half to five drachms of the spermaceti may be taken in the course of the day, and thoroughly digested and absorbed.

The pure fatty acids are given in a mixture of palmitic and oleic acids, two of the former to one of the latter. This mass can be made into pills, which, if keratinized, pass through the stomach unchanged, and are dissolved in the secretions of the intestinal canal and there readily absorbed.

Senator regards the saponified fat-acids (soaps, in short; soda soap; sapo medicinalis) as preferable to either fats or pure fat-acids. Being already in a soluble and

absorbable condition, they make no demands upon the digestive capacity of the intestine. The soap is given in pills, capsules, keratinized pills, or powdered and mixed with sugar and flavored. Senator has used soap in this manner in diabetes, phthisis, obstructive jaundice, cirrhosis of the liver, carcinoma of the stomach, and similar diseases, either of a wasting character or where a deficiency of biliary or pancreatic secretion interfered with the normal digestion of fat. He compares soaps to artificial peptones: the former are pre-digested fats, as the latter are pre-digested proteids. They relieve the overworked or weak digestive organs by supplying the required nutriment in a form ready for absorption.

NOTES FROM SPECIAL CORRESPONDENTS.

THE GERMAN CONGRESS OF PHYSICIANS.

YOUR correspondent has just returned from a trip to Wiesbaden, to attend the sitting of the German Congress for Internal Medicine, which was in session there April 13, 14, 15, and 16. This was the sixth annual sitting of this Congress, and was one of unusual interest and profit. It was a very representative body of German medical men. It included among its numbers also physicians from Austria, Switzerland, France, Holland, and the United States.

Professor Nothnagel, of Vienna, read a paper on *The Localization of Brain-Diseases*, which was discussed at length by Dr. Curschmann, of Hamburg.

Professor Ruhle, of Bonn, read a paper on *The Heredity of Tuberculosis*. The speaker observed that from its very commencement the Congress had been busy with the question of tubercle-bacilli. The Congress has in a manner grown with this question, and it seems its duty not to allow it to become cold. The great discovery of Koch was made just before the opening of this Congress in 1882, and published at its first meeting. It is not to be questioned that the true tubercular poison can originate in the body. As long as tuberculosis has been discussed, heredity has been considered as influencing its propagation. There are two aids to acute infection,—the poison itself, and a suitable ground to receive it.

The speaker then asked how the poison gained entrance into the human race through heredity. This was investigated by Baumgärtner, in 1883, who was of the opinion that the poison penetrated the ovum by way of the semen; that it remained latent in the child ten years or more, and then made its first appearance. The speaker was of the opinion that this theory stood on a very weak basis. The most frequent manner of contracting tuberculosis is from a diseased person through the sputa, and also through the glands, exfoliations of the skin, or any way in which the poison may appear on the surface and be transported by means of pocket-handkerchiefs, washing, etc. The speaker was convinced that the communication of the disease to healthy persons from those affected does not take place through the air. This is an idea which had been demonstrated to no one. Were this true, we could not enjoy life, but would be in continual fear that through some unfortunate breath we might contract the dread disease. The fact that the attendants in hospitals who have the care of consumptives are seldom attacked with the disease leads the speaker to conclude that it is not the air through which the germs are carried, but that it is communicated in another mode,—in fact, the way in which the members of the family kiss and fondle the patient and handle his linen. From one member of the family the tubercle goes to another. Instances can frequently be found on inquiry where the parents transmit the disease to their children. In such cases the family physician should put in his word of warning. The speaker would like to summon his colleagues in practice to take this position in regard to the disease and treat it from this stand-point. It is possible that we will find that the so-called cases of heredity do not need to receive their predisposition through the semen or the mother's blood. If this be acknowledged, then the theory becomes very unreasonable.

The speaker wished further to say that we should hold ourselves aloof from the idea that certain things will bring about certain forms of the disease. For instance, that pulmonary phthisis comes through inhalations, tuberculosis of the alimentary canal through the nourishment, etc. That is only a notion; and when two points are considered,—namely, that scrofulosis is also tuberculosis, and undoubtedly the poison of the tubercles can remain latent an indefinite period,—then we can understand that it is not so simple to lay the origin of tuberculosis to an inhalation of air or to any special primary cause. When a child had acquired a glandular tuberculosis and this heals, and then after fifteen years he becomes tuberculous, according to the opinion of to-day we must believe he had it latent in his system all this time.

The speaker closed his paper with the sentence, "We shall abandon the theory of he-

redity as so far understood, and in its stead place the theory of infection, the family tuberculosis, and closely observe the scrofulosis and latency."

Professor O. Fraentzel, of Berlin, did not agree with the essayist in the statement that the attendants on the tuberculous in hospitals were not infected. He had often made the observation that these attendants died of the disease. He reported from his practice in the Charité at Berlin five such cases.

Professor Lichtheim, of Berne, made an interesting report on *The Coincidences between Pernicious Anæmia and Tape-Worm.* From the cases of this kind which the speaker had observed he has come to the conclusion that tape-worm (Bothriocephalus latus) plays no great part in the causation of disease, yet it has its *rôle.* This, however, is different in the regions about the Baltic, where the people feed largely on fish. The speaker then went *in extenso* into the subject of coincidence of pernicious anæmia with changes in the spinal cord. He had found the anæmia to be the cause of the disease of the spinal cord in two cases in which there was degeneration of the posterior fasciculi of the cord. He related the results of his investigations. The observations he had made lead him to believe the transfusion of blood to be of little use, and that the infusion of salt is dangerous to patients with advanced anæmia.

Professor Rindfleisch, of Würzburg, read a very scientific study of *The Pathological Anatomy of Tabes Dorsalis*, which was listened to with great attention and received with applause.

Dr. Dittweiler, of Falkenstein in Taunus, read a paper on *The Therapeutics of Pulmonary Phthisis.* He had made the disease a life-study, and his paper was very interesting, though quite lengthy. He thought that much more than half of the cases of bacillar phthisis might be completely healed, and by proper care might remain so.

The second gentleman to read on this subject was Professor Penzoldt, of Erlangen, who started with the statement that pulmonary consumption can be healed. After proving this to his own satisfaction, he discussed the question, What can prevent pulmonary phthisis? He answered this from the stand-point that its origin is nothing less than an infection coupled with a predisposition.

1. In the battle with the numerous and invisible tubercle-bacillus, which is scattered broadcast over the whole earth, the chance for its eradication or control is but slight: one can but hope that the government may take in hand this most dangerous of diseases, as it has taken others.

2. We should seek to render harmless the foyer of development of the bacilli in tubercular patients: the possibility of direct infection has long been known from clinical observation. This origin of the disease, fortunately, however, is infrequent. Though this danger is small, yet it exists. On this account it is the duty of the physician to call attention to the danger of intimate relationship with these patients. He must also insist on the greatest cleanliness in the care of the sick, freedom from sexual connection, and unnecessary intimacy in their attendants. The physician should speak out boldly against the marriage of the tubercular, and especially insist on the rules which have been based upon our knowledge of infection. It is more nearly possible to remove the danger of infection on the part of the patients in hospitals. Consequently there must be a hospital for consumptives, or a department for them. The State should watch with the greatest care cattle suffering from murrain, as there is danger of infection from them. The well cattle should be regularly examined with respect to murrain, especially the udders; the diseased animals should be removed, and, where it is possible, destroyed. The most careful examination of animals slaughtered and of the meat put upon the market should be made by competent medical authorities.

3. One must seek to prevent the people from forgetting the danger of infection; especially this must be the case with those who are predisposed, though others are also in danger. The nursing of children by tuberculous mothers or wet-nurses, as well as kissing and tending by tuberculous nurse-girls, should be positively forbidden.

Of great importance is the keeping up of the power of resistance through very rich nourishment, especially meat-diet: the carnivorous animals are less liable to tuberculosis than the herbivorous. The skin and mucous membrane should be hardened; the muscles should be developed, as well as the lungs and the heart, and the respiratory organs protected from dust. The choice of business of the patient is of the first importance: those employments which insure plenty of fresh air—farmer, woodman, gardener, sailor, etc.—are to be recommended. For those who already have the disease the rules of life are in general the same as for those who have inherited the tendency.

The essayist now turned his attention towards the particular curative therapeutics of phthisis. There is, he said, no specific remedy for phthisis. On this account the greatest weight is to be placed on careful attention to the body. In the foreground is the air-treatment. Fresh, pure air, wherever found, must be used with faithfulness; the most curative is the place where little or no phthisis pulmonum is found, or where many have already been cured. Parallel with the air-treatment stands the rational nourishment. The nourishment must be rich as possible, principally albumen easily digested, and must be taken often,—six or seven times a day. The third in order to be recommended is bodily

exercise. The physician should watch over this closely to see that it is carried out. Walks, cautious climbing of mountains, gymnastics in the open air, are especially to be advised. As a fourth point, the hardening of the skin in the case of stronger patients should not be neglected. Lastly, the mental treatment is to be recommended. The physician should encourage the anxious, cheer the despondent, but especially hold the reckless in check. The best guarantee for the carrying out of these rules is the treatment in a hospital in a place possessing as great immunity from the disease as possible. For poor consumptives there is nothing better than good hospitals. The speaker begged his hearers to encourage, wherever possible, the founding of hospitals for phthisical patients in places fitted for them. In the latter part of his address he discussed the medical treatment of phthisis.

The subject of the therapy of phthisis pulmonum was then opened for discussion.

Dr. Brehmer, of the Hospital for Consumptives in Görbersdorf, concurred with the sentiments just expressed. He thought that the tubercular bacillus had given the therapy of phthisis a firm basis. The speaker dwelt particularly on the fact that the question of the immunity of a place is of the greatest weight, even from the stand-point of the believers in the theory of infection. They must, however, be proved certainly to be such by statistics. Such places may be found especially in mountains. Fresh air is there,—also of great assistance. The immunity does not depend wholly on the height, but also upon the geographical position of the place. Indeed, the height must be the greater the nearer the equator it lies. According to Guester, immunity is found in the Austrian Alps only in those places where at a height of more than two thousand four hundred feet the foundation of slate and the ozone regular in amount are to be found. The speaker then gave a brief résumé of his monograph on the subject, published by Bergmann, of Wiesbaden.

The President, Herr Geheimer Medicinal-Rath Professor E. Leyden, of Berlin, in his address laid down the programme of the Congress, and said much in review of what it had done and should do. Every physician knows to what a great extent the medicine of to-day has to thank the natural sciences; he knows that science alone has saved medicine from the pool of arbitrary and inhuman speculation, and founded it anew on the basis of well-grounded facts. The physician must be a searcher of nature. He must learn to observe, prove, and sift the causes of disease in a scientific manner. The task of the physician is, however, not yet exhausted. He has besides the scientific problem a practical side to which he must attend; medicine must be helpful, useful. Those who are inclined to elevate the scientific above the practical must acknowledge that medicine has not a scientific speculation, but a practical demand, to thank for its origin. Every one who has chosen the calling of a physician must undertake the accompanying duties with conscientiousness. He must bring to his assistance in the treatment of his patients all the knowledge and means which in his time medicine will command. Medicine will give up its historical culture and social consideration when it fails to keep in full view this original aim, or even allows it to be placed in the background. It remains our special duty to use the proper remedies for the accomplishment of this task. Medicine must be independent, quite sovereign in this endeavor. To her there is no dogma. Consequently the problem of medicine is not only that of the natural sciences, but there is also another problem which must be solved independently. Above all things, we must not allow the consciousness of the importance of our art to fail us, for medicine is distinguished before all the natural sciences, because she deals with the well-being of our fellow-men. "In this branch of the natural sciences which is called medicine," says C. Hüter, "is prominent the tendency to preserve the life and utility of man." This task gives to our profession her especial importance. Our time is eminently practical, and knowledge should be useful. This practical part is also a beautiful duty which one must fulfil. The field of the laboratory is to study the particular primary causes of disease, to investigate them in their laws, their connections, their actions. Still the experiments remain one-sided necessarily in that only one or few of the appearances are brought out; the great number of symptoms we can only learn at the bedside. The address concluded with some excellent advice to the Congress, and was followed by loud and long-continued applause.

The Pathology and Therapy of Whooping-Cough.—Professor A. Vogel, of Munich, discussed this subject. Pertussis was classified by Gerhardt among the infectious diseases; yet the contagion of whooping-cough is of another nature than that of the acute exanthemata. As concerns the symptomatology, the great clinicians of the last century presented a gastro-pathological theory. In the beginning of the present century the neuro-pathological theory had many followers, but this also fell to the ground as unsuccessful as was the attempt to prove whooping-cough to be a simple bronchial catarrh. There now remains no doubt that it comes under the list of infectious diseases. The essayist here recalled the decision of Linnæus, that the cause of whooping-cough was the inhalation of a contagium animatum, and related the latest revelations of the laryngoscope in the hands of Herffs, of Darmstadt, and likened it to the ideas of Beau, Rehn, Meyer of Hum, and Rossbach. The first found the whole throat hyperæmic, the others found only the posterior

walls to be constantly diseased. The essayist proceeded in relation to the pathological anatomy, saying that in pneumonia following measles and whooping-cough great numbers of microbes were seen by Theon in the pus and lung-cells of the exuded matter, and indeed in whooping-cough pneumonia he had found diplococcus and bacilli in greater numbers than in diphtheritic pneumonia. Marshall described two cases where whooping-cough was complicated with aphasia, stupor, convulsions, and hemiplegia. Wagner reports a case of subcutaneous hemorrhage in a lively five-year-old boy with whooping-cough. In some instances it is a cause of deafness. In the case of a nursing child it is a dangerous and pernicious disease to contemplate; in older children the course of whooping-cough is favorable throughout. In an epidemic in Würzburg, fifty-two children under one year were taken ill, and thirteen, or twenty-five per cent., died; two hundred and forty-six were attacked between one and five, and twelve, or four and six-tenths per cent., died; between six and fifteen years, eighty-seven, of whom one only succumbed. The author lamented that the mortality tables followed the age so closely, notwithstanding the therapeutics. The remedies recommended for whooping-cough are of two great classes,—antispasmodics and disinfectants. In treating the spasmodic cough by narcotics, one resigns every chance of shortening the process; opium or any of its preparations should not be given for any length of time continuously; however, a small dose of opium or morphine is a great relief to children who have passed sleepless nights. A combination of cannabis indica and belladonna is especially recommended by Vettersen, of Humar. Of one hundred and sixteen children, eighty-three showed a favorable result; of these, eighty were completely cured in from eight to fourteen days. Prior and P. Palt recommended the painting of the oral cavity with a solution of cocaine from ten to twenty per cent.; the application of cocaine is not entirely without danger, however. The antiseptic treatment strives to shorten the attack by destroying the germs of the disease. A residence in gas-factories, where the distilled product of the hard coal acts favorably on the mucous membrane of the respiratory apparatus, is first to be recommended. This mode of treatment is sometimes inconvenient. The same gases can be generated in the sick-room by the use of benzine and carbolic acid. After frequent experience, the author did not depend much on this treatment. The inhalations recommended by Pick, of Coblentz, in which fifteen to twenty drops of pure carbolic acid are placed in a cotton ball and inhaled, will be endured but a short time by any child. For general disinfection of the sleeping-room of the patient, Mohn burns twenty-five grammes of sulphur matches to each cubic metre of space. Further investigation in this line is to be recommended. Michael, of Hamburg, blows into the nasal cavities through a glass rod, twenty centimetres long, some powdered resin of benzoin, and besides this uses sulphate of quinine or nitrate of silver in a ten per cent. mixture with lard. The reports from this treatment in the hands of other physicians are favorable. Concerning psychical treatment, nothing new has appeared in recent literature. No followers have been found for the opinion that whooping-cough can be cured only by the rod, fortunately for the poor little patients.

The second paper read on this subject was by Professor Hagenbach, of Basle. He gave a large number of statistics. Two hundred and forty thousand children have the whooping-cough every year in Germany; in Basle, one thousand per year, with twelve deaths; in Geneva, eleven deaths; in London, thirty-six; the rest of England, twenty-two. The mortality is, on the average, four or five per cent. Toplitz reports the mortality from this disease among the children of the Polyclinic, in Breslau, in the years 1875 to 1885, as 7.90 per cent. In Basle, during the last eleven years, the mortality among children under one year has been 26.8 per cent.; from one to two years, 13.8 per cent.; two to five years, 3 per cent.; five to ten years, 1.8 per cent.; ten to fifteen years, 1.8 per cent. These figures show that whooping-cough is a serious disease for the tender years of childhood. With the greatest mortality we have also the most complications.

But what is whooping-cough? The recent investigators are about all united that it is an infectious disease. It comes epidemically, seldom sporadically. In large cities it is endemic and contagious. In whooping-cough we have a catarrh of a certain part of the mucous membrane of the respiratory tract which is connected with the immigration of fungi. At these places, through irritation of the ending of the superior laryngeal nerve, the attacks of coughing are brought on by reflex action.

Professor Hagenbach then discussed the question whether we have to deal with a local or a blood infection. He related the different positions held by Letzerich, Colston, Guéneau de Mussy, Hertf, Rossbach, Meyer of Hum, Lori of Pesth, Rehn, and Baginsky.

The following may be said with positiveness concerning the nature of the contagion. The liability of the human race to this special poison is general. The disease is most frequent in the first year of life, and is found with rarity in the first months. The susceptibility is great up to the tenth year, after which age it becomes less. It is contagious in the first and second stages. So long as mucus is produced, the disease may be carried. Outside of the human body the contagium seems to be unable to exist for any length of time. The reader then discussed the prophylaxis. Schools for small children should be carefully

watched, and children with suspicious coughs kept away as long as they cough in paroxysms. The expectorated material must be carefully removed. If the disease spreads, the school should be closed. The changing of air and place for children infected with whooping-cough is often the cause of an epidemic in places free from the disease. The author then proceeded to treat of the therapeutics, much of which he found defective.

Dr. Michael, of Hamburg, discussed the subject, and recommended a method used by him, in which he blew powder into the child's throat, and gave statistics of his success. In more than one hundred cases so treated he had more or less improved seventy-five. In twenty-five cases, no success at all; in fresh cases his method proved satisfactory, and also in those which had lasted six weeks. The speaker laid more stress upon the qualitative improvement of the cases than on the duration, and circulated through the Congress charts giving the course of the disease under the use of different remedies.

Professor Heubner, of Leipsic, considered the character of the disease to be that of a virulent catarrh, and not a blood-infection. He also exhibited charts showing the numbers of attacks of coughing per day: like the former speaker, he thought it possible to render these attacks fewer and lighter, and eventually to cause the shortening of the disease and its cure.

Dr. Schliep, Sanitäts-Rath, Baden-Baden, recommended the treatment by the pneumatic cabinet which he had used. The increased pressure of air in this cabinet acted mechanically as a sedative on the mucous membrane and increased the inhalations of carbonic acid gas. He found twelve to twenty sittings sufficient to cure a child suffering from whooping-cough. As a further remedy he recommended an emulsion of four grammes of turpentine. He also had good success from smoking the room well with sulphur, twenty-five grammes to the cubic metre of the room.

Dr. Sonnenberger, of Worms, advised the use of antipyrin. He had used it in an epidemic in Worms and vicinity with success. It immediately rendered the attacks milder and shortened their duration.

Dr. Cohen, sanitary officer for Hanover, spoke of the favorable results from inhalations of bromide of potassium, also of the use of the musk preparations.

Professor Unverricht, of Jena, considered the subject of *Experimental Epilepsy*. The lower half of the cortex of the brain contains the centres for the occurrence of epilepsy. Irritation of the cortex will cause attacks of epilepsy. The speaker knew, from experiments he had carried out upon a dog, the importance of the motor region for the muscular spasms.

Professor Rossbach, director of the medical clinic of Jena, read three short addresses: (1) concerning the physiological meaning of the leucocytes which emanate from the tonsils and the follicular glands of the tongue; (2) concerning chyluria; and (3) concerning a *breathing-chair for emphysematous and asthmatic patients*. While till now it has been necessary to use manual treatment of the thorax in order to lighten the severity of asthmatic attacks, a stool had been invented by a patient of the speaker, which enabled him to breathe compressed air without manual aid. The patient takes a seat on the chair and buckles about his chest a girth which is made fast to the stool; on both sides of the chair two arms are situated which the patient moves forward, and which movement tightens the girth four centimetres. By means of this continuous moving of the arms of the chair the patient is enabled to relieve himself. The professor had used such a stool six months in his clinic, and had improved several cases. The advantage this chair has over manual treatment is that through this band the whole thorax is regularly compressed, which is impossible with the hand. Besides, the physician or attendant will be able to carry out the manual treatment for more than half an hour, while the chair can be used as long as desired. Also, this instrument is always at hand for attacks in the night or any time when manual aid may not be available. The professor presented the chair and the patient who had invented it before the Congress, and retired amid great applause.

Professor Schreibe, of Königsberg, related how he had attained the same results through a more simple way,—viz., through elastic corsets.

(To be continued.)

BALTIMORE.

THE AMERICAN CLIMATOLOGICAL ASSOCIATION—A PUBLIC MORGUE—PLEURO-PNEUMONIA AND INFECTED DAIRIES—DIRECTORIES FOR NURSES.

THE Fourth Annual Meeting of the American Climatological Association has just been held in this city. About thirty members were in attendance. Nineteen papers were read, about three-fourths of which treated of climatological subjects, while the remainder were devoted to laryngological or pulmonary topics. To what division of climatology the rectal injection of sulphuretted hydrogen, or the local treatment of the respiratory passages by a spray of Dobell's solution, belongs, does not seem very clear to me.

Some of the papers and discussions possessed considerable practical value, in spite of their apparent inappropriateness on the programme. To this class belongs the paper of Dr. Shattuck on the importance of alimentation in phthisis, illustrated by charts showing the increase of body-weight, and the clear statement of Dr. E. T. Bruen of the scope,

value, and methods of gaseous injection in the same disease.

The subject chosen by the President, Dr. Frank Donaldson, Sr., for his annual address was "Prophylactic Treatment of those who inherit a Predisposition to Phthisis." The question of the hereditary transmission was discussed, the rational position being assumed by the speaker that the disease itself could not be transmitted, but only a predisposition,—a condition of the system which rendered it more vulnerable to the attacks of the specific cause of the disease whenever that gained access to the tissues which are usually the point of attack. Efforts should be directed towards increasing the resisting power of the individual to the cause of the outbreak.

Dr. James R. Leaming read a paper on "The Philosophy of Climatic Treatment of Diseases of the Chest." Dr. Leaming thinks it an advantage for patients affected with this class of diseases to change their abode frequently, in order to take advantage of the improvement generally gained during the first two weeks. Instead of a permanent place at the sea-side for the season, the speaker advised that patients should begin at the northernmost resorts on the Atlantic coast and gradually work southward, stopping two or three weeks at each place. For such patients as could not afford the expense of the present resorts he suggested the establishment of government sanitaria, where the advantages of climatic treatment could be obtained at a nominal cost.

A paper of much interest was read by Dr. R. G. Curtin, of Philadelphia, who pointed out the different manners in which cases of syphilitic phthisis react to sea-air. He detailed five cases of this disease in which marked improvement resulted from prolonged exposure to sea-air, which is contrary to the usual effect of sea-air upon tubercular phthisis.

Most of the climatological papers seemed to be intended to boom certain health-resorts. In fact, the criticism was made in my hearing that the Association seemed to be a convention of persons interested in the development of special sea-shore sanitaria and mineral springs.

A paper by Dr. A. L. Loomis on "Evergreen Forests as a Therapeutic Agent in Pulmonary Phthisis" was an attempt to discuss the climatological problem from a scientific stand-point, and, as such, was fairly successful. Dr. Loomis, however, in discarding the rapidly-dying ozone theory, seems to have overburdened the peroxide of hydrogen hypothesis. As he himself acknowledges, there is a wide difference between elementary meteorology and medical climatology. But without a knowledge of the former no opinion upon the latter is worth much. To an outsider it looks as if a little study of the elements of meteorology beyond what is found in school-books of natural philosophy would be of benefit to some of the members of the Association before they begin to grapple with the more complicated problems. Of course these remarks do not apply to Dr. Loomis.

Nineteen new members were elected.

The following officers were chosen for the ensuing year:

President, A. L. Loomis; Vice-Presidents, A. Y. P. Garnett and J. T. Whitaker; Secretary and Treasurer, J. B. Walker.

The Council consists of E. T. Bruen, J. H. Tyndale, F. H. Bosworth, F. C. Shattuck, and Roland G. Curtin.

The meetings of the Association were held in the beautiful new lecture-hall of the Johns Hopkins physical laboratory.

For a number of years the profession has been active in endeavors to have a public morgue established in this city, but the economy of the City Council or of the Mayor for the time has always rendered all attempts nugatory. Last year the College of Physicians and Surgeons offered to erect and keep in order a morgue, provided a lot of ground adjoining the College and belonging to the city would be sold at a fair price to the College. The Council passed an ordinance to that effect, but the Mayor and Controller, who were authorized to fix a price to be paid for the lot, named such an exorbitant figure that the College declined to have anything to do with it.

About a week ago the trustees of the Johns Hopkins Hospital offered the use of one of their buildings as a public morgue, under the following conditions: "1. The post-mortem examinations at the morgue shall be made by a physician designated by the trustees of the Johns Hopkins Hospital, and appointed, without salary, by the city for that purpose. 2. Post-mortem examinations shall be permitted in all cases where deemed necessary by this physician. 3. The transport and burial of the bodies are to be provided for by the city. 4. All dead bodies which it is customary to send to a public morgue, such as the bodies of unknown dead and those of medico-legal interest, are to be sent to the morgue. 5. Permission to inspect bodies at the morgue shall be obtained by certificate from the health office and the police stations. 6. Unclaimed bodies, as a rule, need not be kept at the morgue longer than ten days, their clothing and effects longer. 7. Special and extraordinary expenses, such as those pertaining to chemical examinations in criminal cases of death by poisoning, are to be borne by the city. 8. The arrangement contemplated in this offer to the city of a morgue by the Johns Hopkins Hospital shall take effect October 1, 1887, and shall continue not less than three years, as the first outlay will be large. The motives which induce the trustees to make the foregoing proposition are: first, the desire of making the hospital as useful as possible to the city; second, the belief that the work

which should be done in a morgue, and the methods which ought to be employed in medico-legal autopsies, are subjects for which it is very desirable that systematic and skilled instruction should be given for the benefit of justice and of the public; third, the desire that the medical department of the Johns Hopkins University, with which the hospital is closely connected, may be able to give this instruction in a thoroughly satisfactory manner."

This is an extremely liberal proposition, but there are certain legal difficulties in the way, which will probably prevent its acceptance. As the second and seventh conditions would conflict with the duties and privileges of the coroners, who are State officials, it looks as if the city would be deprived of the advantages of a public mortuary chamber until our municipal rulers can be made to see its importance.

Quite a sensation was created here last week by the State Veterinary Bureau, which seized upon a dairyman's stable and killed all the cows found upon the premises on account of pleuro-pneumonia. It is said the post-mortem examination verified the diagnosis of pleuro-pneumonia in some of the cases. The authorities would have been justified in breaking up this man's business even if no pleuro-pneumonia existed in his herd, for I have been informed that the filthy and unsanitary conditions under which the cows were kept made it impossible for these animals to retain their health. Pleuro-pneumonia has been quite prevalent in some parts of this State, and all the power at the command of the national and State authorities is being invoked to stamp it out. Infected herds are promptly quarantined, and diseased animals killed. It is hoped soon to exterminate the epidemic here.

We have now two directories for nurses,—one managed by the Medical and Chirurgical Faculty, and a recently organized one under the auspices of the Woman's Medical College. The latter is, in connection with the Training School for Nurses, managed by the College.

G. H. R.

June 1, 1887.

PROCEEDINGS OF SOCIETIES.

AMERICAN SURGICAL ASSOCIATION.

(Continued from page 576.)

Second Day, Morning Session.

THE Committee of Conference with reference to the proposed Congress of American Physicians and Surgeons reported that they had attended the meeting of conference held in Washington, September 24, 1886, which adopted the following resolutions:

"*Resolved:* 1. That it is desirable that the following special Societies—the American Surgical Association, the American Ophthalmological Association, the American Otological Association, the American Neurological Association, the American Laryngological Association, the American Gynæcological Association, the American Dermatological Association, the American Climatological Association, with the Association of American Physicians—shall arrange for a conjoint meeting in the city of Washington, September, 1888, and subsequently at intervals of three years at the same time and place.

"2. That this arrangement shall not interfere in any way with the autonomy of each special Society, and that each Society shall retain the right to withdraw at any time from this conjoint scheme.

"3. That the special feature of the meeting shall be the conjoint assemblage of the special Societies on two evenings during the session, on one of which there shall be an address delivered by the President of the conjoint meeting, and on the other there shall be communications by a referee and co-referee on some subject of general professional interest.

"4. That each special Society approving this report is invited to appoint one representative (with an alternate), and that the representatives so appointed shall constitute an Executive Committee, to serve for one year, with power to select such officers for the first conjoint meeting as may be deemed necessary, to propose a programme for said meeting, to make all other arrangements, and to prepare and submit a plan of organization for future meetings.

"5. That all expenses connected with the conjoint sessions shall be apportioned equally by the Executive Committee among the special Societies participating.

"Owing to the views entertained by the Committees of the Ophthalmological and Dermatological Associations with regard to the interval of times of meeting, they abstained from voting upon the first resolution."

The report was adopted, and Dr. C. H. Mastin, of Mobile (with Dr. J. Ford Thompson, of Washington, as alternate), was appointed as the representative of the Association.

The following were appointed as the Nominating Committee: Drs. J. Collins Warren, J. H. Brinton, T. F. Prewitt, N. P. Dandridge, and D. W. Yandell.

The Treasurer, Dr. P. S. Conner, reported a balance of $738.46 in the treasury.

DISCUSSION UPON SUPRA-PUBIC LITHOTOMY.

The discussion of papers read on Wednesday was then taken up.

Dr. W. T. Briggs, Nashville: Dr. Dennis, in his paper, held that the time would come when supra-pubic lithotomy and litholapaxy would practically be the only operations per-

formed for the removal of stone. His idea was that no special operation is applicable to all cases. The surgeon should have all operations at his command, and should select the one adapted to the particular case. In certain cases, such as large stones, or deformities of pelvis and lower extremities, supra-pubic lithotomy is undoubtedly the best operation. There is, however, no reason why, in ordinary cases of medium-sized stones, the perineal operation should not be adopted. He regarded this operation as the best, as the external wound permits dilatation to any extent. The neck of the bladder is usually resistant, but by making a lateral incision of three lines on each side of the prostate gland, with gradual dilatation, the opening can be enlarged to an extent sufficient to permit the removal of any stone that should be removed through the perineum. A number of stones (varying from one to one and a half inches in diameter) which had been removed in this way, with recovery of the patient, were then exhibited by the speaker. There is no reason why crushing a large stone should not be combined with the medio-lateral operation. The operation is easier than the lateral operation. Incision in the manner mentioned, with the removal of all stones at once, he thought, would have a less mortality than litholapaxy.

Taking all kinds of cases at all ages, his first seventy-four cases were operated on by this method without a death. Then he had two deaths: in one a pelvic abscess complicated the case, and in the other there was scrofulosis. Forty-six cases were then operated on without one death. One did die three months after operation with general tuberculosis, but with the wound united. It is probable that in properly prepared patients without organic disease the mortality will be nothing. In the last two years he had operated upon six old men, at an average age of sixty-six years; all recovered.

Dr. D. Hayes Agnew: As Dr. Briggs has said, we cannot commit ourselves positively to any one method. The median is undoubtedly the safest operation through the perineum. The only damage likely to be done is in extraction, but this can be avoided by nicking the neck of the bladder, which allows distention to almost any extent. Where the stone is large, and yet is one which should come through the perineum, an incision may be made on each side. Drainage is more readily effected by the perineal operation. With proper antiseptic precautions the success of this operation will be even greater than at present. In cases of large stone the high operation is the best. When one has operated year after year through the perineum, as Dr. Briggs and others of us have done, with almost universally successful results, he is indisposed to give up what he believes to be a well-tried method for one which is a comparative novelty.

Dr. J. R. Weist, Richmond, Indiana, after seeing Dr. Briggs perform the medio-bilateral operation, had adopted this method in eight cases, all of which recovered. With one exception, all the patients have been old: this one was twenty years of age, from whom a mulberry-calculus weighing five hundred and twenty grains was removed. The next youngest case was fifty-nine years old, eight stones being removed. In another case, seventy-two years old, twenty-two stones were removed. From the accounts of the supra-pubic operation given yesterday, he inferred that the operation is more difficult of performance than the one described by Dr. Briggs.

Dr. H. H. Mudd, of St. Louis, said that his first operations were performed by the perineal method with good results. He subsequently adopted litholapaxy, which in the majority of cases takes the place of the perineal operation. The supra-pubic operation is of service for the removal of certain large stones and for exploratory purposes. In considering this operation, it must be borne in mind that the existence of contracted bladder with adhesions will render the supra-pubic operation difficult or impossible.

Dr. J. Collins Warren during the past year had seen two cases of the supra-pubic operation, both in the practice of others. One was for stone, and the other for tumor. There seemed to be no difficulty in the operation; both cases recovered without a bad symptom. After investigating the subject of cystotomy in the female, he had reached the conclusion that there need be no apprehension of causing vesico-vaginal fistula.

Dr. Theodore Varick, of Jersey City, two years ago had operated on a boy, 14 years of age, who had had symptoms of stone for seven years. He started with the left lateral operation, but on account of the size of the stone had to carry the incision to the right side. The stone removed weighed seven ounces and two scruples. There was no perceptible laceration, and the boy recovered completely. In cases where there was hemorrhage he had used with advantage the application of water just under the boiling-point, saturating a sponge and placing it for a short time on the bleeding surface.

Dr. David W. Yandell said that he had performed ninety-two operations by the perineum, eight by lithotrity, and six by litholapaxy. He had seen two supra-pubic operations, but it did not seem to him that this operation is an easier or better one than those mentioned. There were seven deaths from the lithotomies. In none of the cases was there any return of the stone. In the eight lithotrities there was a return of the stone in two cases; in the six Bigelow operations there was a return in two cases. The question in his mind is still *sub judice*, and until more evidence has been presented he will adhere to the opinion that the best operation is that made through the perineum.

Dr. John B. Roberts, of Philadelphia, still held the opinion which he expressed three years ago,—that the high operation is certain to be a very important one. If we wish to make a free exploration of the bladder, the high operation is better than the one through the perineum. In cases of stone operated on by a surgeon without special experience in this direction, the supra-pubic operation is the safer. With reference to Dr. Packard's suggestion to treat retention of urine from stricture by supra-pubic cystotomy, he should consider this too serious a step to take in the first place. His own view was that persistent efforts should be made to introduce a filiform bougie, which would drain off the urine. Simple aspiration above the pubes will give a chance for the passage of an instrument through the urethra in two or three days.

Dr. J. E. Michael, of Baltimore: With reference to supra-pubic opening of the bladder for retention due to stricture or prostatic disease, in his considerable experience in this direction he had never found such an operation necessary. Supra-pubic aspiration seems to be all that is necessary, and under proper precautions is safe. Then in prostatic cases the use of a soft catheter will accomplish all that can be done except some radical operation is attempted. In cases of stricture this must be treated. As to the advisability of the supra-pubic operation for exploration for some cases of prostatic enlargement and for exceptional cases of foreign bodies, there can be no question.

A STUDY OF THE PROCESS OF REPAIR AFTER RESECTION OF THE INTESTINES, AND SOME OF THE COMPLICATIONS WHICH OCCUR. BY J. COLLINS WARREN, M.D., OF BOSTON.

The speaker first referred to the anatomy of the wall of the intestine, calling particular attention to the thin submucous fibrous coat, which was the strongest of the various coats of the intestine. The peritoneal and muscular layers, as well as the mucous layer, are easily rubbed away, but this fibrous coat is exceedingly resistant. In introducing the sutures in cases of wound of the bowel, it is desirable that a few fibres of this fibrous coat be included, but care must be taken not to perforate the mucous membrane. The fact that this has been reached is readily told by the resistance offered to the needle. A number of experiments made upon dogs were then described. The operation consists in removing a portion of the intestine and a V-shaped portion of mesentery, and then bringing the parts together; the Lembert suture was the one used. After the operation the bowel was replaced in as near its normal position as possible. The dogs were killed at varying times after operation, from three to eight days. In these cases the intestines were found matted together around the seat of operation, but a current of water flowed freely through the gut. In one case the abdomen was opened a few days after operation, and this matting together of the various coils of intestine found. The intestine was replaced and the wound again closed. Six months later most of the adhesions were found to have disappeared.

SHOULD LAPAROTOMY BE DONE FOR PENETRATING GUNSHOT-WOUNDS OF THE ABDOMEN INVOLVING THE VISCERA? BY CHARLES B. NANCREDE, M.D., OF PHILADELPHIA.

In presenting this subject for the consideration of the Association, the chief object is a medico-legal one. A few years ago, in a famous murder trial the counsel urged the acquittal of the accused on the ground that the fatal result had been induced by the surgeon probing a penetrating gunshot-wound of the abdomen, and many authorities in support of this position were cited. At present the tendency is towards more active interference in these cases. The author asked that, after a consideration of the subject, the Association —the highest surgical tribunal of the country —should express an authoritative opinion upon this question. The questions to be decided are, What are the tendencies of the injury? are they towards recovery or towards death? When death takes place, what are its causes? When recovery ensues, what conservative processes occur? How likely are these conservative processes to take place, and what favors or prevents them? How reliable are unaided natural methods compared with those which art affords, and should they be imitated or avoided by the surgeon? What are the dangers inherent to the operation of laparotomy, and what advantages does it afford?

Reference was made to the experiments of Wegner and Gerwitz, showing that the healthy peritoneum can dispose of air, serum, bile, and healthy urine. When, however, air and putrescible fluids in greater amount than could be disposed of in a short time were introduced, decomposition occurred, and septicæmia resulted. A notable exception was that living defibrinated blood never decomposed under these circumstances. This seems to prove the truth of the suggestion of the author that the presence of fibrin-ferment and probably its absorption is one of the dangers of peritoneal traumatism. The ordinary micro-organisms produce no evil effects, provided the quantity of putrescible matter does not exceed that which may be disposed of in a short time. In small quantities the pathogenic micro-organisms produce no harm. Suppurative peritonitis is produced by these micro-organisms when stagnant fluids are present capable of nourishing the bacteria, when the surface of the peritoneum has been destroyed by caustic fluids, and when there is a wound of the peritoneum.

The practical application of these experi-

ments teaches that all blood and serum should be removed and free drainage provided; every wounded surface must be coaptated; if a tube be used, the opening must be carefully guarded; the depression of the circulation present during shock must be removed, and the vascularity of the peritoneum must be kept as near the normal as possible.

When visceral wounds do undoubtedly exist, the tendency of these cases is invariably towards death. Hemorrhage in itself is rarely fatal, but a very small collection of blood may be followed by fatal consequences either through the induction of sapræmia or by furnishing pabulum for the development of organisms productive of suppurative peritonitis. In nearly every case death is due to septic peritonitis caused by extravasated matters. Of those attacked with peritonitis, ninety per cent. die within twenty-four hours. When recovery ensues, the effused matter is absorbed and a limited adhesive peritonitis glues the injured organ to the abdominal walls or to a neighboring viscus. This process is successful in about eight per cent. of the cases.

The conservative processes are favored by absence of effused fluids, or, if present, only slight flatulent, fecal, urinary, or biliary extravasation; by the absence or only slight amount of effused blood or serum; by the favorable relation of the wound to neighboring viscera or the abdominal wall; but above all by the aseptic condition of the peritoneum, of the wounds and their immediate surroundings, and by complete arrest of the intestinal movements. It is apparent that nature's methods are not to be relied on.

He said that the dangers of laparotomy are shock, and the risk of rendering a peritonitis septic and diffused which might have remained local and simple; but, as we have the power of rendering the inflammation resulting from the manipulations innocuous, shock is practically the only result to be dreaded.

If these facts and the deductions from them be true, all bullet-wounds of the abdomen involving the stomach, intestines, gall-bladder, or urinary bladder, should be treated by suture or by resection and suture; injured omentum should always be excised, and the serous surfaces carefully sutured. Wounds of the liver and pancreas are to be treated in the manner to be described. A wounded spleen or kidney is to be removed, provided certain contra-indications do not exist. Even penetrating wounds of the abdomen without involvement of the viscera are better treated by exploratory section than by the expectant method. In many instances unsuspected injuries of the blood-vessels and viscera will be found and appropriately treated. The speaker laid but little stress upon most of the symptoms said to be diagnostic of wounds of the viscera, and held that the diagnosis should be made by the eye alone. The track of the ball should be enlarged, under aseptic precautions, until it has been determined whether or not the peritoneum has been opened; then median section should be performed to ascertain the existence of and repair any damage that may have been done. The above remarks can apply only to wounds of the anterior and lateral walls of the abdomen. When the posterior wall is involved it is unadvisable to ascertain the fact of peritoneal penetration by direct exploration. In these cases a correct opinion is almost always difficult, and often impossible, without laparotomy.

The rational signs of peritoneal or visceral lesion were briefly mentioned. The escape of bile, fæces, urine, or the contents of the stomach at once determines the question of visceral penetration. These signs are, however, rare even when visceral lesion is present. Repeated vomiting of considerable quantities of blood almost certainly points to peritoneal or visceral penetration. This symptom is unlikely to be present, even when there are numerous wounds, unless one involves the stomach or upper portion of the small intestine. The passage of blood in quantity by the bowel is strong presumptive evidence, but it rarely occurs early enough to be of practical diagnostic value for operative purposes. The presence of fluid within the abdomen within an hour or two after the injury is a positive indication of peritoneal penetration and probable visceral injury, for only intra-peritoneal hemorrhage could produce such rapid accumulation of fluid. The rapid accumulation of intestinal gas in the general peritoneal cavity is a sure sign of wound of the peritoneum and of the gut. To be of much value it must appear within a short time after the injury. Finally, an amount of hemorrhage which cannot be accounted for after a careful examination of the parietal wounds indicates penetration and vascular or visceral lesion.

Profound shock, if not due to hemorrhage, is a contra-indication to operation. The surroundings should not contra-indicate operation in a proper case, provided the operator be expert in abdominal surgery. Most cases will do better if left to nature than they will if operated on by a bungling surgeon. If well-advanced peritonitis exists, laparotomy is not to be done. Where there is no visceral complication, operation under these circumstances may sometimes be justifiable. Laparotomy, if done at all, should be done at the earliest possible moment that the condition will permit. Shock is the only thing that should delay the operation, and this should not do so if the condition is produced by hemorrhage.

In operating, strictly antiseptic precautions should be carried out. The incision should always be median, extending from a short distance above the umbilicus to two inches above the pubes. Unless there be free hem-

orrhage, the small intestines should be carefully gone over, keeping them constantly enveloped in towels wrung out of hot water. Afterwards the stomach, spleen, kidneys, bladder, etc., must be carefully examined. The source of a severe hemorrhage must at once be sought after. Wounds of the bowel should be secured with the Lembert suture and dusted with a little iodoform. Wounds of the liver, if occupying its free border, should be coaptated, if possible, with dry aseptic catgut, which will soon swell and fill the track made by the needle. If this cannot be done, the hemorrhage possibly may be arrested by the thermo-cautery; or, if the bleeding be free, the wound should be plugged with an iodoform-gauze tampon. If at the close of the operation the bleeding is almost completely checked, the cautery may be used as a further protection and the tampon removed. If, however, the bleeding is still free, the tampon should be replaced and allowed to remain permanently. Wounds of the pancreas, spleen, and kidneys are to be treated in a similar manner. If these measures fail, a spleen or kidney should be removed. Wounds of the bladder had better be united with dry catgut. Contused portions of the bowel should be excised. Wounded or contused omentum or mesentery should also be removed. In removing a portion of the bowel, the cuts should correspond to the distribution of large mesenteric vessels. Should the pulse fall during the operation, flushing the abdominal cavity with hot water is often of service. The peritoneal toilet is most quickly and effectively made by irrigation with warm sterilized water and subsequent removal with sponges. Wounds of the peritoneum should be united. In closing the abdominal cavity the peritoneum should be sutured with fine silk or catgut. The muscular, aponeurotic, and cutaneous structures should then be united with strong silk. The wound should be dusted with iodoform, and the dressing completed by the application of a pad of absorbent cotton and a flannel bandage.

Alimentation should be carried on by the rectum for forty-eight hours when possible. Where peritonitis comes on after the operation, its treatment will depend upon whether it has developed rapidly or gradually. In the former case there is often evidence of shock from vaso-motor paresis, and in these cases small doses of morphine with atropine will be of service, while large doses of opium may prove fatal. This should be continued until pain is relieved and the patient falls into a quiet sleep, from which he is readily aroused. In the latter stages of peritonitis one or more hypodermics of atropia will at times save otherwise hopeless cases. For the control of the vascular processes involved in peritonitis we have two powerful measures in the ice-coil to the abdomen and in the use of leeches if applied early and if the patient has not lost much blood. If the temperature continues to rise despite treatment, it is probable that ptomaines are being absorbed, producing sapræmia. In such cases, irrigation with safe antiseptic fluids is indicated.

In concluding, the speaker stated that everything advanced was to be viewed as more or less provisional, since sufficient experience in the operative treatment of these cases has not accumulated to warrant positive statements.

Thursday, Afternoon Session.

PISTOL-SHOT-WOUND OF THE ABDOMEN TREATED BY LAPAROTOMY AND SUTURING THE INTESTINES. BY R. A. KINLOCH, M.D., CHARLESTON, SOUTH CAROLINA.

J. B., colored, aged 27, was admitted into the City Hospital January 21, at 7.30 P.M. He had been shot, two hours before, in the abdomen with a pistol-ball (.38 calibre). The ball entered one and one-half inches to the left of the umbilicus. There was moderate shock. The patient seemed to be comfortable, with the exception of a slight pain on the inside of the left thigh, which was intensified by movement. Pulse 88, respiration 24, temperature 99°. At 10 P.M. half a grain of morphine was given hypodermically, and shortly afterwards anæsthesia was induced by the A. C. E. mixture. Penetration of the peritoneum was first determined, and the abdomen was then opened by median incision. A weak carbolic spray was used. The intestines were examined piece by piece and wrapped in towels wrung out of a one to ten thousand bichloride of mercury solution. The jejunum presented four wounds,—two of entrance and two of exit. The ileum had two wounds. The mesentery was perforated in two places, and was also badly torn. There was free bleeding from a mesenteric branch, which was controlled by pressure-forceps, and subsequently by ligature of silk. All the wounds were closed with the Lembert suture, using a fine round needle and antiseptic silk. The wounds of the mesentery were brought together as far as was possible, but there was an infiltration of blood which could not be removed. The abdominal cavity was washed out with a weak solution of bichloride of mercury. The abdominal wound was closed with silver sutures, and a large rubber drainage-tube introduced. Antiseptic precautions were observed throughout the operation. The next morning vomiting occurred, and an examination of the wound showed that a suture had given way and a knuckle of intestine protruded. This was returned, and the opening closed. At 5 P.M. the temperature was 102°. Vomiting again occurred, and shortly after midnight the patient expired suddenly.

Post-Mortem.—No adhesion of the parietal peritoneum had occurred. Half a pint of

dark sero-sanguinolent fluid was found in the cavity. All the intestinal sutures had held, and there was no fecal extravasation. A circumscribed abscess was discovered in the meso-colon, out of the line of the bullet. The ball was found behind the body of the fourth lumbar on the left side.

This was the third case in which the author had performed laparotomy for bullet-wounds of the abdomen without visceral protrusion. In two cases of such injury the patients recovered without operation. The first operation was performed May 27, 1863. This patient recovered. The operation was performed seven months after the injury. There had been but one discharge from the bowels, and the patient was gradually sinking. This was the first time that laparotomy had been done for gunshot-wound without protrusion.

PISTOL-SHOT WOUND OF THE ABDOMEN, INVOLVING THE LIVER, STOMACH, SUPERIOR MESENTERIC VEIN, INTESTINE, AND KIDNEY — LAPAROTOMY — NEPHRECTOMY — DEATH ON THE FIFTEENTH DAY—AUTOPSY.

This paper was read by W. W. Keen, M.D., of Philadelphia.

Miss B., in Vineland, New Jersey, a plump and healthy, well-developed girl of nearly 18, shot herself with a pistol (calibre .32), at 6.30 A.M., April 1, 1887. Dr. O. H. Adams, who arrived in a few moments, found that the ball had entered over the liver, and after a careful search found it lying under the skin of the left flank.

I saw her at 2 P.M. She told me that the wound was self-inflicted; hence the pistol had been almost in contact with the body, and the ball had probably passed in a straight line. The wound of entrance was over the ninth rib, which was fractured, four and a half inches above the level of the navel, and three and three-quarter inches to the right of the median line. Skin not burned. The ball was located eight inches to the left of the median line, one and a half inches above the level of the navel. There was moderate tenderness over the entire belly; hepatic dulness not changed; stomach resonant from fifth interspace; no cough, no râles; vocal fremitus normal; renal dulness began at tenth rib on left side, and was the same on the two sides. There was severe pain in the left shoulder. She had vomited a drachm and a half of clear bright blood, she told me, immediately after the accident. About a pint of urine, the first since the accident, was drawn by the catheter; it was not bloody. Pulse 104, respirations 30. No material rise of temperature.

As, after consultation with Drs. Adams and Bidwell, it was deemed almost certain that the belly was invaded by the ball, exploratory laparotomy was advised, consented to, and begun at 3 P.M., and lasted nearly three hours, with every antiseptic precaution. The ball was easily removed just under the skin. Neither wound could be traced positively into the belly. On opening the belly, neither blood nor serum escaped. Nor was any extravasated food or fæces noticed. There was no peritonitis. Two fingers were passed in and an effort made to discover the wound of entrance or exit, without any being revealed by touch. The wound was then enlarged and the stomach drawn out. A small round wound near the pylorus was found, and was closed by four sutures (Lembert) of the finest iron-dyed silk, a round ordinary sewing-needle being used. This wound was practically closed by the pouting mucous membrane. As the ball had entered the stomach, search was made for the necessary wound of exit. None was to be found; but the manipulation showed that a small amount of bloody serum existed in the belly, and a large area of extravasation was seen in the mesentery. But little blood had escaped into the peritoneal cavity. The mesentery was carefully torn through and a small artery tied. The chief bleeding came from a hole nearly one-eighth inch in diameter in a large vein, so large and lax that at first I thought it the vena cava; but its position just below the head of the pancreas convinced me that it was a large superior mesenteric vein just before it forms the portal vein. After much difficulty, I seized it with hæmostatic forceps and placed a lateral ligature of chromicized catgut on it.

The anterior border of the liver had been scalloped by the ball, but, as there was no bleeding, it was let alone. In addition, a large wound in a coil of small intestine in the left flank had been found. Ten Lembert sutures were used in closing it.

Returning now to the stomach, a very careful search was again made for the wound of exit. It was found obscured by a slight coating of blood. This was closed by three black silk Lembert sutures.

A systematic investigation of the entire bowel from the stomach to the sigmoid flexure showed no other wound. The left kidney was badly lacerated, and was immediately removed by peeling it out of its capsule and tying the pedicle with a stout silk ligature. A rubber drainage-tube was inserted through the wound of exit into the abdominal cavity.

The wound of entrance was cleansed, and closed by three stitches, and the wound of exit by two sublimate-gauze rubber dams, and a wide flannel bandage completed the dressing.

During the day following the operation suppression of urine was threatened, only three and a half ounces being secreted: this was quite albuminous. The next day, however, the amount rose to twenty-four ounces, and on the third day to forty ounces, and the albumen gradually disappeared. For the first three days nothing was given her except cracked ice, ice-water, and a little whiskey and champagne. On the fourth day pepton-

ized milk in frequent but small quantities was allowed, with rectal enemata of the same, and later other liquid foods. Menstruation appeared regularly when due on April 3, and pursued its usual course of four days. On the 8th she had a chill lasting twelve minutes, and the temperature rose to 104°; but as the most careful examination revealed no spot of special tenderness, no dulness, no fluctuation, and she was almost, it seemed, *in articulo mortis*, it was not deemed prudent to re-open the belly.

The next day, the 10th, she improved somewhat. On the 13th she had another chill, with a temperature of 105.4°; had vomited several times, and also had some involuntary evacuations. But, as her condition was fair, pulse 136, temperature 101°, the belly was reopened and explored. The intestines were bright and glistening, and no peritonitis existed.

Surgical bimanual examination revealed no pus or special tenderness at the site of the removed kidney, or, so far as it could be located, at the intestinal wound. No shock followed. The next (14th) she had two bloody motions, and gradually failed, dying on the fifteenth day.

The autopsy, by Dr. H. C. Smith, revealed general peritonitis except in the pelvis, but no free pus was found anywhere. Only one wound was found in the stomach, near the pylorus, and this was healed, the four stitches being seen in place. The blood in the mesentery was disintegrating and suppurating, though no abscess existed, nor was there any free pus in the peritoneal cavity. The suppuration was chiefly marked along the mesenteric attachment of the intestine. On the other side of the mesentery corresponding in position to this wound was a spot on the bowel-wall as large as a five-cent coin which was gangrenous, and in its centre were two perforations of the bowel. No wound was found except that discovered at the operation. No trouble was found at the site of the removed kidney. Although it was nearly ten hours from the accident to the time when the intestine and stomach were sutured, no intestinal or gastric juice or fluid escaped, although the intestinal wound was so large, and vomiting occurred three times.

The kidney, I believe, has never before been removed at a laparotomy for gunshot-wound, but it was clearly the right thing to do. The day following the operation the remaining kidney worked badly, only three and a half ounces of albuminous urine being secreted; but the next two days dispelled all anxiety on this score, the urine rising to twenty-four and forty ounces respectively, and the albumen soon disappeared. The early and marked compensatory enlargement of the right kidney is also of great interest and importance, though of course now well known to follow nephrectomy.

DISCUSSION.

Dr. P. S. Conner, of Cincinnati: When an operation is required, we are all agreed as to what should be done; but the most important point to determine is, *When* should the abdominal cavity be opened? The question of diagnosis is of great importance. If there is extravasation of bile, fæces, or urine through the wound, the nature of the injury is clear; but in the absence of these signs there is much doubt. There is no single symptom or collection of symptoms to be relied upon. He had been disposed to attach some value to the presence of profound depression of temperature. If the temperature remains subnormal four, five, or six hours, penetration and perforation may be considered almost certain. Diagnostial laparotomy is admirable in certain cases. In private practice we have to be largely governed by the opinions of the patients and friends. Many of these cases necessarily involve legal investigation, and it is a very simple matter to show that death resulted not from the original injury, but from the surgeon's knife. While it is wise to lay down the general rule that penetrating wounds of the abdomen—and still more perforating wounds of the viscera—should be submitted to laparotomy, at the same time we are not justified in laying this down as a hard and fast rule.

Dr. Moses Gunn, of Chicago: When Dr. Sims proposed this operation a few years ago, the profession was not ready to accept it. We are now all prepared to say that it is a proper method to pursue, but the only question is how to make the diagnosis. We have, as has been said, no positive signs of visceral injury. We are now fully warranted in saying that we may resort to laparotomy for purposes of diagnosis when we are in doubt.

Dr. T. Richardson, of New Orleans, looking over the statistics of the Charity Hospital of New Orleans, had found that in the last five years there were thirty-one cases of penetrating knife-wounds of the abdomen, of which twenty-four recovered and seven died. There were thirty-three cases of gunshot-wound of the abdomen, with thirteen recoveries and twenty deaths. Laparotomy was performed in one of the fatal cases of gunshot-wound; all the others were treated on the expectant plan.

Dr. D. Hayes Agnew, of Philadelphia, said that he had some very strong convictions in regard to laparotomy, and believed that, where there is a reasonable degree of evidence that there is a penetrating wound of the abdominal wall, especially of a shot-wound, it is the surgeon's duty to make an exploratory incision. We are not to be deterred by the possibility of some legal technicality if the case should come into court. We are to do our duty, without reference to the consequences.

Drs. David Prince, Joseph Ranschoff, and

N. P. Dandridge also reported cases bearing upon this discussion.

REPORT OF A CASE OF VENTRAL HERNIA SUCCESSFULLY TREATED BY OPERATION, WITH A SUGGESTION AS TO THE METHOD OF OPERATING. BY J. EDWIN MICHAEL, M.D., BALTIMORE.

Mrs. F., stout woman, 45 years of age, had a ventral hernia resulting from a fall several years previously. Great annoyance was experienced in the use of pads and bandages. The longitudinal opening was about two and a half inches in length. The patient insisted on operation.

March 15, 1886, the operation was performed. Antiseptic precautions were adopted. Free incision was made in the median line. The sac was carefully separated from surrounding tissues. It was then emptied of its contents and opened. The sac was cut off close to the margin of the ring. Strong silver-wire sutures were passed a little less than one-half an inch apart, having a hold of one-half to three fourths inch. The sutures included the peritoneal, muscular, and tendinous structures only. These were twisted, and perforated shot employed. The wire was then cut off close. The skin and subcutaneous tissues were secured with catgut sutures. A half-dozen catgut strands were placed in the wound for drainage. The wound united rapidly. In October, examination of the wound showed it to be firmly united. The sutures could be felt, but gave no inconvenience. In his remarks the speaker stated that his object in using the wire sutures in this manner was the expectation that they would be surrounded by a mass of cicatricial tissue, making a permanent closure of the ring. As far as he was aware, he had used the wire for this purpose without precedent.

A paper on "Prognosis in Sarcomata of the Breast," by Dr. S. W. Gross, of Philadelphia, was read by title and referred to the Publication Committee.

THE MEDICO-LEGAL ASPECT OF CRANIAL AND THORACIC WOUNDS (SUICIDAL). BY D. HAYES AGNEW, M.D., OF PHILADELPHIA.

The study of this subject had been suggested to him by a recent case occurring at Newport, Rhode Island. The question was as to the possibility of a cranial wound and a wound of the heart being self-inflicted. A colored man was found one morning lying dead under the breakfast-table. He had food in his mouth, and had a wound of the head and of the heart. The coroner's jury rendered a verdict of suicide, and the body was buried. Subsequently it was disinterred and the verdict reconsidered, and the conclusion reached that the man had been murdered. Suspicion then fell upon the son-in-law of the man, who had up to this time borne a good reputation. At the trial five medical experts were called for the prosecution, and their general testimony was that these wounds were incompatible with the idea of suicide. Subsequently the prisoner confessed that he had committed the murder. As this was an important question, the author had investigated it. There are two conditions resulting from injury of the head which would prevent the infliction of a second injury: these are unconsciousness and paralysis of one or both upper extremities. Injury to the brain is not necessarily followed by loss of consciousness or by paralysis. Many cases were cited to show the truth of this statement. Numerous instances of heart-injury were given in which, after the reception of the accident, the individual was able to perform many acts. Cases were also given in which persons, in attempting suicide, had produced injuries of the head and of the heart. As the result of his study, the speaker concluded that it is possible for a ball to enter the brain without destroying consciousness, although for a moment it may cause mental confusion, and that a suicide may shoot himself in the head, and after a moment shoot himself in the heart.

In the discussion which followed, numerous cases were related in which the heart or brain had been injured and the individual had lived for some time and had not been unconscious. Cases were also given in which both a wound of the brain and of the heart had undoubtedly been produced by the individual himself.

(To be continued.)

OBSTETRICAL SOCIETY OF PHILADELPHIA.

MEETING OF APRIL 7, 1887.

(Continued from page 579.)

OVARIAN CYST SIMULATING OCTOPIC GESTATION. (REPORTED FOR DR. F. A. PACKARD.)

MRS. T., Italian, white, æt. 29; married the second time about two years ago; had five children, all by the first husband; no miscarriages; labors all easy and natural; made good recoveries, and nursed all her children. Menstruation regular in time and quantity until November, 1886: it was absent in November and December.

For the past month she had been bleeding freely, the hemorrhage appearing in clots mixed with what seemed to be shreds of decidua. The breasts tingle, but are not apparently enlarged; face blotchy; no abdominal enlargement noticed. She has had nothing like labor-pains. The discharge is of bad odor. She has had no fever or chills.

Examination showed a cystic tumor in the pelvis, to the right of the uterus, about the size of a gravid uterus of the second month.

Operation.—On January 10, the patient being etherized, an incision three inches in length was made in the median line of the abdomen, just above the pubis. Hemorrhage from the abdominal wound was slight. A small cyst of the right ovary was found, consisting of two chambers,—one being filled with clear serous, the other with darker, blood-stained fluid. There were no adhesions. The cyst was removed unruptured, the pedicle ligatured with silk and returned. The cyst was about the size of a small orange, and sprang from the right ovary. The patient's condition after the operation was excellent. She had no rise of temperature or pulse, and no pain. Four stitches were removed on the fifth day, and the remainder on the seventh day. There has been no return of the bleeding.

ABDOMINAL SECTION FOR INTESTINAL PERFORATION. (REPORTED FOR DR. FRANCIS L. HAYNES.)

Mrs. M., aged 20, nullipara, had suffered for nearly a year from diarrhœa, cough with purulent expectoration, and symptoms produced by uterine disease and general weakness. March 9, 1887, she was suddenly seized with severe abdominal pain, which shortly became intense in a spot two inches to the right of the median line and three inches above Poupart's ligament. The temperature varied from 100° to 104°; pulse from 120 to 140. Vomiting and purging and slight ballooning were other symptoms. The attending physicians, R. and F. L. Haynes, diagnosticated peritonitis from intestinal perforation.

As the patient gradually became worse, Dr. Joseph Price made abdominal section on March 14. The intestines were found matted together. They were washed and wiped with sponges. Two pieces of fecal matter, each about the size of a pea, together with some serum, were removed from the cavity. The abdominal pain and swelling now diminished, and by the third day after the section had entirely disappeared. The temperature gradually sank to the normal. On the seventh day the patient became delirious, collapsed, and died on the morning of the eighth day after the section. No autopsy was allowed. It was thought that general tuberculosis was the cause of death.

PYOSALPINX IN ITS RELATION TO PUERPERAL FEVER.

Dr. J. M. BALDY presented this specimen not simply because it was one of pyosalpinx, but because of its extremely important relation to the puerperal state, and, as far as he is aware, because it is the first of its kind ever operated upon and life saved when the patient was dying from so-called puerperal fever. The patient, Mamie P., 23 years of age, was delivered of a male child, after a tedious but normal labor, some four years ago. She was at that time confined to her bed for eight weeks with "an inflammation in her stomach." She, however, made a good recovery, and has not suffered from pain or ache in her abdomen since. On February 3, 1887, he was called to attend her in her second labor. Although he went with the messenger, he found the labor over: a dead child, together with the placenta and all the membranes intact, lay between her thighs. Her uncovered arms, chest, and legs were exposed in a room without a fire. No examination was made, but she was put between warm, dry bedclothes as quickly as possible. On the second or third day she had a chill, with a quick rise of pulse and temperature, and a tympanitic and tender abdomen. These symptoms abated somewhat, and he lost sight of her for several weeks. On the 3d of March, one month after her confinement, he was again summoned to her, and found that she had been suffering ever since he had last seen her. She had become so emaciated that he hardly recognized her; her temperature 102°+, pulse 130; she had continued chills and creeps, hectic, night-sweats, and sleepless nights; her abdomen was swollen and tympanitic and intensely painful; her bowels loose and fetid; micturition and defecation were both painful. She was evidently fast approaching death. An examination of the soft parts showed no sign of a recent tear. The uterus was subinvoluted, and on the left side there was a large boggy mass firmly adherent, tortuous, and extremely tender. The right side was tender, but no mass could be detected. Abdominal section was advised as the only remaining hope of saving her life, and the proposition was eagerly accepted by the patient and her friends. Dr. J. Price saw the patient and confirmed the opinion of immediate operation. He operated on March 5, the delay being necessary in order to have her surroundings cleansed. Drs. J. Price, McMurtrie, of Danville, Kentucky, and Mr. Eckman, of Scranton, Pennsylvania, were assisting. The right tube and ovary were healthy, and were not removed; the left tube was almost as large as the uterus, and firmly adherent in all directions, especially to the bowels, from which it was separated with great difficulty. An abscess of the cellular tissue was ruptured while breaking up the adhesions, and pus welled up through the abdominal incision. Both tube and ovary were removed. A large cheesy mass on the bowel at the point of adhesion was trimmed down with scissors, and Monsel's solution applied to the bleeding points. After a free irrigation a drainage-tube was put in, and the incision, which was only one and a half inches in length, was closed. The tube was found to be distended with pus; the ovary was disintegrated and contained pus. The patient rallied quickly, and had no shock; her pulse fell to 80 and her temperature to normal within twelve hours, and remained so. The tube was re-

moved on the seventh day. There had been little or no pain; no catheter, no laxative or drug of any kind, had been employed. The day after the removal of the tube her pulse began to rise, as also did her temperature; pain developed in the left ovarian region, and she began to have hectic and cold creeps. About the eleventh day there was a free gush of pus from the tube-tract, and she began to improve again from that moment. A rubber tube was inserted and passed deep into the pelvis, and the abscess was washed out twice daily. The discharge gradually diminished, and the tube was again removed. The wound is now completely healed, and the patient is a well woman.

The belief that a certain proportion of our puerperal fever cases are simply cases of salpingitis septica is by no means a new one, and is probably held by most of the great operators in the world. Dr. M. Sänger says that "salpingitis septica coexisting with severe puerperal septicæmia has never as yet given the surgeon an opportunity to remove the principal focus of disease by the extirpation of the tubes. It is possible, however, that under certain circumstances such a procedure might be indicated." Dr. Carl Schroeder holds that "septic endometritis does not extend to the tubes, as a rule. Occasionally, however, it does go on to a purulent salpingitis." That these cases do exist much more frequently than we have had any idea of is certain, and that oftentimes a life otherwise doomed can be saved by operative interference is proved by the case presented to-night. Mr. Tait mentions four deaths from this cause in Queen Charlotte Hospital alone, and says "that these cases were, during life, all regarded as puerperal fever." Dr. A. Martin, out of a total of two hundred and eighty-seven cases, found that seventy resulted from the puerperal state. Dr. Sänger mentions two cases which have come to his knowledge in which the over-distended tubes burst and discharged pus into the abdominal cavity, with death on the fourth day after confinement in one case and on the twenty-first day in the second case. He thinks that in both these cases the salpingitis existed before delivery, and mentions a case in his own practice in which this certainly was the condition. Hecker, as early as 1878, mentions two cases in which the pyosalpinx was old and was only lit up by the puerperal state. Whether the disease arises *de novo* or, having already existed from other causes, is simply lit up by the puerperal state, must be determined in each individual case. Hecker's and Sänger's cases, as mentioned, had a pre-existing salpingitis, but in the seventy cases reported by Martin the micro-organisms of puerperal septicæmia were found in the contents of the tubes, and no mention is made of any other micro-organism, so it is fair to presume that these cases arose from the puerperal state pure and simple. Of course the possible contagion of gonorrhœa can never be eliminated except by a microscopic examination. In his case, although the trouble seemed very clearly to have arisen at the time of the second labor, possibly with her first labor also, yet the chances of gonorrhœal infection both before and after her first pregnancy are so great that he cannot pretend to say it was not present. The operation has up to this time been done at least four times in Philadelphia. One case was operated on just two weeks previous to mine by Dr. Longaker, in which a pyosalpinx was found and removed, the patient dying on the second day. Dr. J. Price has since operated twice, and in one case found more than a quart of pus in the abdominal cavity. The case unfortunately fell into his hands too late, and the patient survived only two days. These cases, though few in number, certainly teach us that the work done in this direction is encouraging, and, although a large percentage have died, it only warns us of the extreme importance of an early diagnosis and prompt surgical interference. It becomes our imperative duty in every case of post-puerperal trouble to make a thorough investigation of the case on the appearance of the first symptoms, and should a fulness be found on either or both sides of the uterus, accompanied by pain on touch and with constitutional symptoms of gravity, there should be no hesitation as to the course to pursue. This being secured, our present high mortality of one woman out of every hundred delivered in large cities, as recently stated in a statistical paper on lying-in charities in the United States, must be largely diminished, and the fatal influences now surrounding our parturient women must become infinitely less.

Dr. J. PRICE remarked that the operation in this case was difficult and tedious, and was done with great care. He believes that conception can take place coincident with desquamative salpingitis. Salpingitis even of gonorrhœal origin may affect one tube only, and the other, being normal, may give exit to an ovule. Six months ago he removed a large pus-tube from the right side; the woman is now four months pregnant. If he finds induration and distention of a tube with inflammatory symptoms during the post-parturient period, he does not hesitate to operate at once, the operation involving less danger to the patient than the rapid progress which the inflammatory process will take at that period. He read from a letter from Mr. Tait, "There can be no doubt as to the frequency of the occurrence of puerperal pyosalpinx, and what we want to do is to hammer at people until we get them to open the abdomen in primary puerperal peritonitis." Dr. Price does not think septic post-partum salpingitis would be unilateral. He would also call attention to the extreme degree of degeneration that has taken place in the tissues of the tubes themselves, and most commonly unilateral only: they are

quite cheesy in character. This change could not occur in so limited a space of time, a few days only.

Dr. LONGAKER remarked that one of the four cases referred to by the author of the paper was a patient who was under his care, and who died forty hours after operation. Briefly, the history of the case is as follows. A young woman from Maryland came to his office, being in the sixth month of her first pregnancy, for treatment for a profuse mucopurulent discharge having all the characteristics of a recent gonorrhœa. A month later, premature labor set in. The child did not live. The placenta came away entire. Four days after labor she began to complain of a severe pain in the left inguinal and hypogastric regions, paroxysmal and associated with great tenderness. The tongue was dry, but there was no nausea or vomiting. There was no chill, but the temperature was slightly elevated. The same symptoms continued for the next two days. On the eighth day, 7 A.M., she began to complain of intense cutting pains; temperature 96.5°, pulse 96. Four hours later, under the free use of morphine, the pain was relieved, the temperature had risen to 102°, and the pulse to 120. Dr. Joseph Price kindly saw the case with him, and agreed on the advisability of laparotomy. During the afternoon her temperature continued to rise, reaching 104° in the evening. On the following day she was much better, was free from nausea and vomiting, and had no severe pain. Owing to this apparent improvement, Dr. Longaker allowed himself to be persuaded to put off operating. The abdomen was opened February 14, 1887, the ninth day after delivery, and nearly sixty hours after the onset of acute peritonitis. General peritonitis and a large quantity of pus in the region of the left cornus uteri, exceedingly foul in odor, were found. The left tube was removed; it was an inch in diameter. The uterus was fairly involuted; it was firmly fixed in the pelvis. The wound drained freely, but incessant vomiting set in, and the patient died forty hours after operation. Is it not assuming too much to say these cases had pyosalpinx before conception? He is sure such was not the case in his patient. Though she had lived irregularly with a man for some five years, she had had at no time such symptoms as would lead us to suspect this disease. It would be possible, if pyosalpinx be the consequence of a poison from without, to find entrance to the tubes during the first three and a part of the fourth month, before decidua vera and reflexa become firmly united, but the result would most likely be an abortion at the time of the invasion. The morbific matter probably obtains access to the tubes after parturition is completed, and owing to the combined circumstances acts in an explosive manner. Is not the pyosalpinx originated after labor as the result, it may be, of a gonorrhœa contracted between conception and labor or before conception?

Dr. HIRST presented a specimen from a case of

VIRULENT PUERPERAL SEPSIS,

by permission of Professor Parvin, in whose service the case occurred.

The specimens are interesting not merely because they come from a case of puerperal fever, which unfortunately is not a rare disease, but from the rapidity with which the disease terminated fatally, and from the possible point of entrance of the septicæmic poison. The history of the case before delivery presents nothing worthy of note. Immediately after delivery the temperature was 99.5°, and in spite of the most energetic antiseptic treatment of the vagina and uterine cavity the temperature rose to 102°, but dropped again to 99.5°, only again to rise to 102°, where it remained till the woman's death, about seventy-two hours after the birth. The post-mortem examination showed diphtheroid patches in the vagina extending into the cervical canal; the uterine cavity and walls were normal; the peritoneum, tubes, and ovaries healthy; the kidneys were the seat of numerous metastatic abscesses, and there were several infarcts in the liver; the lungs were healthy; the rectum was covered with extensive patches of diphtheroid membrane,—a very interesting condition, for it indicates the possibility that here was the point of infection, and if this is the case this specimen assumes considerable importance, for he knows of only three such cases recorded in medical literature,—one by Winckel, the others by Koester and Von Recklinghausen. These specimens may well serve to call attention to the possibility of infection by the administration of enemata, and to the importance of observing the most minute precautions as to the chemical cleanliness of every instrument that may come in contact with the parturient or puerperal woman.

A LARGE OVARIAN CYST CURED BY EVACUATION, DRAINAGE, AND OBLITERATION OF ITS CAVITY.

Dr. W. H. PARISH: On January 27, 1887, I operated on a Jewess, 27 years of age, for the removal of a large abdominal cyst. I saw the patient for the first time on January 24. She was then under the care of Dr. N. Hickman, who placed her under my care for operation. She was the mother of four children, the youngest only four months of age. In her last labor she had been attended by a midwife, and but little reliable information could be obtained with reference to the existence of an abdominal tumor during the three weeks following labor. The patient stated, however, that her abdomen was not unusually large after the birth of the child. About three weeks after labor she was under the care of Dr. Hickman for a few days, during which time she presented the usual symptoms of general

peritonitis. She then passed into the hands of others, and was not seen again by Dr. Hickman until just before I operated. During this period of three months she was visited by a number of medical gentlemen. Aspiration was resorted to by one of the number. Laparotomy was repeatedly urged, but persistently refused by the patient. The abdomen increased rapidly in size; pain became constant; appetite entirely disappeared; vomiting occurred at very short intervals; hectic became marked, with occasional rigors, and emaciation had reached an extreme point. The lower extremities were but slightly œdematous, and there was no special enlargement of the superficial abdominal veins. The abdomen was greatly distended, tense, and tender, and the patient was so exhausted that she could not rise from the semi-recumbent position. She was at once transferred from her surroundings of filth and poverty to a private hospital, and I operated without delay, as it was apparent that without surgical relief her life could last but a few days longer. There were present Drs. Hickman, R. P. Harris, S. D. Lazarus, John Hand, and F. A. Packard. The patient had a general sponge bath with soap and water, and stimulants had been administered. Before etherization the pulse was 130 per minute; there was a dull percussion-note over the entire abdomen anteriorly, and the diaphragm was pushed well upward by the tumor. Fluctuation was distinct, though palpation suggested a thick-walled cyst rendered very tense by reason of the degree of distention. I gave a diagnosis of ovarian tumor, with suppurating contents and extensive adhesions. Incision two and a half inches long in median line: without opening the peritoneal cavity the knife cut into the cyst-wall, which was easily recognized by its consistence, color, and anatomical elements. There were anterior adhesions of great extent and firmness. The cyst was opened, and a quantity of pus-like fluid of offensive odor escaped. The cyst did not empty itself, and the introduction of two fingers showed large masses of lymph-like character, varying in density and size. The introduction of the hand was required to remove these masses. In the interior were a number of thin septa, such as are seen in colloid ovarian tumors. The great bulk of the contents was an apparent mixture of pus, lymph, and detritus, while part of the contents presented the translucent appearance of the fluid of some ovarian tumors. After thoroughly emptying the tumor it was evident that its walls were everywhere adherent. No portion of the wall could be brought into the abdominal incision. There were evidently dense adhesions to the liver, spleen, stomach, intestines, and to the pelvic brim and contents. The tumor did not dip down into the pelvis; the walls were everywhere thick and strong. At this stage of the operation the patient's condition seemed threatening imminent death: pulse 140, and exceedingly feeble. The ether was withdrawn, and was not used again; stimulants were given hypodermically. The thickness of the cyst-walls and the universal adhesions rendered the case one well adapted to treatment by drainage. I decided not to remove the cyst. I now thoroughly cleansed its interior, introduced a glass drainage-tube, and approximated around it the walls of the abdomen and cyst, carrying the sutures into the cyst-wall but not through it.

The patient rallied well, and there was no ether-vomiting. For several days the discharge through the tube was of a purulent fluid similar to portions of that removed during the operation; its character then changed to that of ordinary pus. The cavity of the cyst was daily emptied of about two ounces of fluid, and phenol-sodique injected in the same quantity. The abdomen was covered with a compress and binder, to keep the inner cyst-walls approximated and to encourage absorption of the exuded lymph. The area of dulness diminished rapidly from day to day, and the discharge diminished with surprising rapidity. At the end of two weeks a shorter drainage-tube was substituted, and at the end of three weeks rubber tubing about three inches in length was introduced in lieu of the glass tube. The wound was entirely healed by the end of the fourth week. Examination showed a small flattened mass, two by one inches, underlying the abdominal wall and adherent to it. The patient's appetite became ravenous a few days after the operation, and she was fed liberally. The recovery of the patient is now complete, and I feel confident the cyst-cavity is so effectually obliterated that it cannot refill. Does the rapidity of the shrinkage and disappearance of the cyst indicate that it was not an ovarian tumor? I answer in the negative. It was not an extra- nor an intra-peritoneal abscess, for abscesses do not contain such septa nor such fluid. The character of the contents and septa distinguishes this case from two cases operated on by Tait, in which he ascribed the tumors to distention and suppuration of sacculated urachus. In making the incision I recognized the peritoneum external to the cyst. In my own mind there is no doubt as to the ovarian origin of the tumor. A specimen of the fluid was examined microscopically by Dr. F. A. Packard, who has written as follows:

"I found it to be composed of numerous fatty degenerated epithelial cells, leucocytes, and granular material, entangled in a dense mesh-work of fine, homogeneous, fibrin-like fibres. There appeared to be no definite arrangement or other evidence of an organized tissue. The general appearance was that of a tissue that had undergone complete fatty degeneration. I unfortunately ruptured the small cyst before I could collect the contents for examination."

The entire paper will be published in the *American Journal of Obstetrics*.

Dr. R. P. HARRIS remarked that the cyst-contents consisted chiefly of a thin greenish fluid of a puriform character, in which were found masses of cell-structure, some of them as large as a fist, on the surface of which were in some instances still to be seen small translucent cysts containing a yellowish fluid; there was also noticed during the emptying process an escape of fluid from cells which had preserved their integrity, and which resembled to the eye what is often seen in tapping during ovariotomy of multilocular tumors. His own impression during the operation was that the tumor was ovarian. The emaciated state of the woman, her rapid pulse, and the strong adhesions of the cyst-wall to the abdominal parietes and viscera, satisfied him that any attempt to remove the cyst would cause the patient to die either upon the table or of shock in a few hours. Judging from the recoveries after the secondary operation in abdominal pregnancies, where it has been found of vital importance not to remove the cyst,—a measure the value of which was discovered by an accident more than ninety years ago in New York City, which occasioned its being left *in situ* and eventuated in saving the woman's life,—it was decided to adopt the same plan here. When the abdominal wound was closed in Dr. Parish's case, the thick cyst-wall could be felt like a large disk, with edges more than half an inch thick. As the disintegrating process thinned the cyst-walls, contraction of the disk took place, and the centre of the abdomen became deeply fissured, until the diameter of the disk was not more than three inches, and it was also much thinner; this change continued until the percussion-sound showed no dense structure beneath the abdominal wall. As the ovarian tumor was so altered in structure by peritonitis that its lining surface could no longer secrete ovarian fluid, there was no risk of the formation of a discharging fistula, and the wound rapidly closed as the sac contracted.

Dr. B. F. BAER remarked that he thought Dr. Parish acted wisely in not attempting to remove the source from which the fluid was secreted. He was led to express this opinion, first and mainly, because the doctor was not sure at the time of operation that there was a tumor, and, secondly, because of its very close adhesion, if a tumor existed. He questioned the ovarian origin of the fluid in this case upon the following conditions, as stated by the author: 1st, the difficulty of diagnosis before operation; 2d, the character of the fluid,—absence of the ovarian cell especially; 3d, the fact that the secretion so readily ceased after the sac had been opened; 4th, because there was such a rapid disappearance of the cyst-wall. It is so well known to all of us that the secreting surface of a true ovarian tumor is not destroyed by tapping or drainage that we have come to regard tapping and even drainage as very bad practice, where the tumor can be removed even at considerable risk: free drainage and injecting the tumor were long ago given up as futile in the cure of ovarian tumors. Then the sac of an ovarian tumor does not soon undergo atrophy and absorption, even if the secreting surface is destroyed. The cases of extra-uterine pregnancy mentioned by Dr. Harris, in which the sac disappeared so readily, were doubtless of the abdominal variety, and the gestation sac therefore largely, if not entirely, adventitious. This was probably the character of the sac in a case upon which he (Dr. Baer) operated some time ago and removed a full-term child which had been dead thirteen months. The fœtus only was removed. A drainage-tube was placed in the sac. The patient recovered, and all remains of the fœtal envelope have disappeared. Dr. Baer would admit, however, that the fluid in the case reported to-night was very like ovarian, except in the absence of the ovarian cell, which he regarded as of very great diagnostic value in a doubtful case. He requested the President to express his opinion concerning the absence of the cell in this case.

Dr. DRYSDALE remarked that it would be very difficult to detect the ovarian cell in such a mass of purulent matter, but if the fluid of the child-cysts had been examined the cell would most probably have been found. He dwelt upon the importance of the investigation of the fluid being made by one familiar with the appearance of the ovarian cells and those resembling them, as without such experience it is difficult to differentiate the cells. Dr. Drysdale referred to an obstetric case which Dr. Parish had attended for him four years ago. This lady suffered from a tumor some years before, which proved to be a dermoid cyst developed in the posterior wall of the uterus. During its growth it formed a communication with the bowel, and a great quantity of offensive fluid escaped in this way. The opening into the bowel closed, the sac filled again, the patient emaciated rapidly, and septicæmia set in. Aspiration was resorted to, and a quantity of very offensive matter removed, after which the cyst was washed out with a five-per-cent. solution of carbolic acid; this was repeated nine times at intervals, the patient declining any other operation. She had now become so emaciated that every process of bone showed through the skin, and her pallor was extreme. In this condition, with a pulse of 140 and a temperature of 105°, she finally submitted to an operation. Before this was commenced she was told that it was not likely that the tumor could be removed, as from its location in the uterine wall and its former communication with the bowel it would probably be found firmly adherent to the surrounding parts. He therefore proposed opening the abdomen, and if the tumor was found to be as he apprehended he would stitch the edges of the cyst to the

lips of the abdominal incision, insert a large drainage-tube, and close the wound. This was done, and, although the case was so unpromising, she made a good recovery, while the cyst gradually contracted and finally disappeared, but there still remains a fistulous tract where the tube was inserted, which occasionally discharges matter. She became pregnant about three years after the operation, and was delivered of a male child by Dr. Parish, who informed him that she had an easy labor.

Dr. JOSEPH PRICE had no doubt of Dr. Parish's case being an ovarian cyst. He had seen the patient and had recommended operation.

Dr. PARISH remarked that the walls of the cyst were largely composed of adventitious material, the result of inflammatory processes breaking up the original substance, and hence in part the explanation of the rapid cure of the case.

MISCELLANY.

THE American Medical Editors' Association held its Annual Meeting and Banquet at the Palmer House, Chicago, June 6, 1887. A large increase of membership and the warm interest shown by those present indicated a degree of prosperity hitherto unknown in the history of the Association. Preparations were made to have a meeting at Washington during the session of the International Congress, in order suitably to entertain medical editors from abroad.

IODOL AS A SUBSTITUTE FOR IODOFORM.—Dr. R. Norris Wolfenden prefers iodol to iodoform because it is odorless, anæsthetic, and undoubtedly antiseptic. A number of preparations containing this new agent are referred to in his communication to the *Practitioner* for May.

SULPHUROUS ACID IN WHOOPING-COUGH.—Fumigations of burning sulphur of the bedchamber during the temporary absence of the patient are highly recommended by Dr. Mohnk, a Norwegian physician.—*Therapeutic Gazette.*

NOTES AND QUERIES.

OBITUARY.

EDME FÉLIX ALFRED VULPIAN, born in 1826 at Paris, recently died in the city in which he had attained well-deserved pre-eminence, in the sixty-first year of his age. His lectures on Comparative Physiology, published in 1864, and followed by "Leçons sur la Physiologie du Système Nerveux," led the way to his great works on the Vaso-Motor System and Diseases of the Nervous System, which place him in the foremost rank as a physiologist and pathologist. He was Professor of Comparative and Experimental Pathology, and for several years Dean of the Faculty of Medicine. His death was caused by infectious pneumonia.

OFFICIAL LIST

OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U.S. ARMY FROM MAY 22, 1887, *TO JUNE* 4, 1887.

MAJOR B. E. FRYER, SURGEON.—Granted two months' leave on account of sickness; permission to apply for an extension. S. O. 28, Division of Pacific, May 28, 1887.

MAJOR V. B. HUBBARD, SURGEON.—Granted leave of absence for one month, to take effect on or about June 1, 1887. S. O. 119, A. G. O., May 24, 1887.

CAPTAIN PAUL R. BROWN, ASSISTANT-SURGEON.—Granted leave of absence for four months. S. O. 126, A. G. O., June 2, 1887.

CAPTAIN H. O. PERLEY, ASSISTANT-SURGEON.—Relieved from duty at Fort Maginnis, Montana Territory, and ordered for temporary duty at Fort Snelling, Minnesota. S. O. 49, Department of Dakota, May 23, 1887.

CAPTAIN H. G. BURTON, ASSISTANT-SURGEON.—Granted two months' leave of absence, on surgeon's certificate of disability. S. O. 107, Division of Atlantic, May 25, 1887.

CAPTAIN F. W. ELBREY, ASSISTANT-SURGEON.—Found incapacitated for active service by an Army Retiring Board; sick leave still further extended until further orders on account of disability. S. O. 116, A. G. O., May 20, 1887.

FIRST-LIEUTENANT LEONARD WOOD, ASSISTANT-SURGEON.—Ordered for temporary duty at Fort Huachuca, Arizona Territory; relieved from duty at Headquarters, Department of Arizona. S. O. 126, A. G. O., June 2, 1887.

FIRST-LIEUTENANT WILLIAM N. SUTER, ASSISTANT-SURGEON (recently appointed).—Ordered for temporary duty at Washington Barracks, D.C. S. O. 122, A. G. O., May 27, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U.S. NAVY FOR THE TWO WEEKS ENDING JUNE 4, 1887.

PASSED ASSISTANT-SURGEON C. W. DEANE.—Detached from the "Dale" and to Hospital, Mare Island.

SURGEON H. P. HARVEY.—Orders to the "Iroquois" revoked and wait orders.

PASSED ASSISTANT-SURGEON S. H. DICKSON.—Detached from Navy-Yard, Washington, D.C., and to the "Dale."

SURGEON J. R. WAGGENER.—Detached from the "Iroquois" and wait orders.

ASSISTANT-SURGEON S. STUART WHITE.—Ordered to Receiving-Ship "St. Louis," Navy-Yard, League Island.

DR. JAMES G. FIELD (of Gordonsville, Virginia).—Commissioned Assistant-Surgeon in the Navy, May 23, 1887.

SURGEON JOHN F. BRANSFORD.—Ordered to the Smithsonian Institution, Washington, D.C.

SURGEON J. RUFUS TRYON.—Detached from the U.S.S. "Quinnebaug" and ordered home.

SURGEON CHARLES A. SIEGFRIED.—Ordered to the U.S.S. "Quinnebaug."

ASSISTANT-SURGEON WILLIAM MARTIN.—Detached from the U.S.S. "Pinta" and ordered home.

PASSED ASSISTANT-SURGEON HENRY B. FITTS.—Detached from the Receiving-Ship "Vermont" and ordered to the U.S.S. "Pinta."

ASSISTANT-SURGEON JAMES G. FIELD.—Ordered to the Receiving-Ship "Vermont."

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U.S. MARINE HOSPITAL SERVICE FOR THE SIX WEEKS ENDING JUNE 4, 1887.

GOLDSBOROUGH, C. B., SURGEON.—Detailed to represent the service at the meeting of the American Medical Association at Chicago, Illinois, June 6, 1887, June 1, 1887.

BANKS, E. C., PASSED ASSISTANT-SURGEON.—When relieved, to rejoin station at Boston, Massachusetts, May 23, 1887.

NORMAN, SEATON, ASSISTANT-SURGEON.—When relieved, to rejoin station at Cape Charles Quarantine, May 26, 1887.

PHILADELPHIA, JUNE 25, 1887.

ORIGINAL LECTURES.

CLINICAL LECTURE

ON CASES REQUIRING AMPUTATION OF MAMMARY GLAND FOR HYPERTROPHY, AND EXCISION OF THE HIP-JOINT FOR COXALGIA.

Delivered at the Jefferson Medical College Hospital, Philadelphia,

BY J. M. BARTON, M.D.,

One of the Attending Surgeons to the Hospital, etc.

Reported by Dr. J. M. FISHER, Clinical Assistant.

GENTLEMEN, — This patient, Ellen W., aged 17 years, single, a slightly-built colored girl, has an enormously enlarged left breast. Her family history is good, and she has enjoyed perfect health since childhood. She menstruated regularly until four months ago, but not since.

This breast became slightly and temporarily increased in size about three years ago. One year ago, while but little if at all enlarged, it began to grow rapidly, until it now measures twenty-seven inches in circumference; it is distinctly pedunculated, its circumference at the base being only twenty-one inches. Its outline is quite regular, its surface perfectly smooth; the superficial veins are greatly dilated, some being as large as the little finger; the nipple is retracted and surrounded by an eczematous eruption probably due to pressure, as this is the most dependent part of the growth.

Upon palpation, I find no distinct tumor in any part. It is more dense than the normal breast, and in all parts it feels as though an irregularly-coiled, small, hard rope were between the fingers. There is no sensation of fluctuation, little if any increase of heat, no discoloration, and it is not adherent to the skin nor to the deeper tissues. There is no glandular enlargement in the axilla. The other breast is apparently normal.

The size of the growth, the age of the patient, and the absence of any distinct tumor, exclude at once scirrhus, fibroma, myxoma, the smaller adenomata, and the solid sarcomas.

The absence of fluctuation excludes all cystic growths, and, I might say, excludes the softer varieties of sarcoma. Though rapidly-growing round-celled sarcoma, or any form with a large number of small cysts, frequently bears a strong resemblance to this condition, yet the absence of all fluctuation, of any decided heat, and of any pain, together with the great uniformity of the outline of the growth and the good general condition of the patient, excludes all suspicion of this form of malignant tumor.

We have here a simple hypertrophy of all the glandular apparatus. The ducts, the acini, and even the fibrous stroma are increased, and in such growths it has frequently been found that the fibrous stroma has made distinct, small, fibroid tumors. It differs markedly from the normal breast in the entire absence of fat. On microscopical examination of such growths we find some fibrous stroma, though less in proportion than in the normal gland, but great increase in the glandular elements, so that the tumor can be classed as an adenoma, or as a fibro-adenoma.

This form of tumor is quite rare: the late Professor S. D. Gross, in his Surgery, recorded but one case that came under his personal observation. Professor Agnew recorded only two, and Professor Billroth, in his book on Mammary Tumors, also states that he has seen but two cases.

Such tumors occur most frequently about the seventeenth, or from this to the twentieth, year, just after the beginning of menstruation, though some exceptional cases have occurred as late as the forty-third year. Of thirty reported cases, the average age was less than twenty-three years, though thirteen of them were under twenty and twenty-one of the thirty were under twenty-five years.

Both breasts are usually enlarged in this disease, one more than the other. In thirty-four reported cases both breasts were diseased in twenty-two cases, the right alone in seven, and the left in five.

If permitted to remain, they incommode by their size and weight and interfere materially with the individual earning her livelihood. Occasionally they are the cause of death. I find reports of three fatal cases. The first, reported by Dr. Grähs, was a young woman of fifteen years of age, in whose hypertrophied breast "abscess after abscess formed, sinuses ran in all directions, and, notwithstanding an enormous discharge of pus, the breast continued to increase in size."

She perished with pyæmia five years after the beginning of the disease.

The second case died with exhaustion, and the third with gangrene of the hypertrophied breast.

In the patient before us I will remove the entire growth, making skin-flaps to cover the wound, adopting the usual antiseptic precaution with which you are so familiar, as you have seen all your clinical teachers use them here for several years. As most of these cases bleed quite freely, I will surround the base of the gland with an Esmarch's tourniquet while I am fashioning the flaps, and will then rapidly remove the breast, seizing such vessels as spring with these Pean's forceps, which I find very serviceable under such circumstances. After all the vessels are secured by catgut, the wound again thoroughly flushed with the bichloride solution, the flaps are brought together with the continuous catgut suture and the antiseptic gauze applied. Of course there is no danger of any return of this disease.

[*Note by reporter.*—The dressing was removed the following day saturated with bloody serum, fresh mercurial gauze was applied, and, as the temperature remained normal, it was not redressed for ten days, when the wound was found to have healed without a drop of pus.]

COXALGIA: EXCISION OF THE HEAD OF THE FEMUR.

Levi L., æt. 8 years, has suffered for three years with coxalgia, the disease being now far advanced in the third stage. You see the thigh, buttock, and back are riddled with sinuses, the leg is flexed to a right angle with the pelvis, and the patient is thin, exhausted, and nervous.

Under ether, I find the leg shortened, the trochanter being two inches higher than it should be. The leg rotates freely, the femur rotating on its own axis, showing that the head and neck are separated from the shaft and probably long since broken down and discharged with the pus.

Making a free incision down to the bone, we find the trochanter carious and softened, and as two of the many sinuses are nearly in this line I shall carry my incision through them. Now rapidly raising the thickened periosteum with this special elevator of Dr. Sayre, then dividing it transversely at the point where I propose making the section of the bone,—that is, about three inches below the upper extremity of the trochanter,—I now readily loosen the periosteum entirely around the bone, and by means of a Bellocq's canula draw the chain-saw into position, with which the bone is now divided, then grasping the trochanter with a "lion-jawed" forceps it is held firmly while the muscles are separated. The trochanter and the remains of the neck are now lifted out.

I am glad to say there is no disease of the acetabulum. The carious portions have long since been separated and discharged, and the cavity of the acetabulum is filled with healthy granulations. The sinuses are now scraped, and drainage-tubes passed through some of them. The wound and the sinuses are flushed with bichloride solution, a large drainage-tube is laid in the wound, and the wound brought together.

The boy is placed at once in the apparatus known as "Sayre's wire cuirass," which extends from head to foot, covering the posterior half of the body.

It has a fenestra opposite the wound, permitting it to be dressed without disturbing the granulations which will form about the new joint.

Full extension is kept up, so that the sawn end of the femur may be opposite the acetabulum, otherwise the femur would travel up to the situation formerly occupied by the trochanter. The extension is made by adhesive plaster applied to the leg in the usual manner. The cord from the adhesive plasters runs through this pulley fastened to the apparatus just below the foot, and it then passes upward to be attached to a strong piece of elastic the upper end of which is firmly fastened some distance up on the wire cuirass. This maintains a constant tension of about six pounds. The boy is prevented from slipping down by the well foot pressing against this adjustable wooden foot-piece. In this apparatus he can be readily handled; it is not necessary to remove him from it to relieve either bowels or bladder, or to dress the wound. He can be given a change of air, he can even take a drive in a carriage.

After the cavity left by this operation has filled with granulations, the joint will be fixed by plaster or some other form of apparatus. He will then be permitted to walk on crutches, with a sole some inches thick on the well foot to keep the diseased leg from contact with the ground, and thus maintain extension by the weight of the pendent extremity.

ORIGINAL COMMUNICATIONS.

ON BLISTERING THE SURFACE OF THE BODY IN INTERNAL INFLAMMATIONS.

BY ENOS T. BLACKWELL, M.D.

OUR medical fathers had a few remedial forces which they wielded in many different conditions and with powerful effect. The theories for their action were definite in their minds, and they wavered not in driving them to a definite conclusion. That they were always judicious in the exercise of these powerful agencies can hardly be affirmed; yet we cannot fail to admire the clearness of their views, the firmness of their convictions, and the boldness of the ensuing practice.

With the revolution of years and the innovation of modern speculations, the methods so long and faithfully relied upon began to be questioned in men's minds, and by a rebound—peculiar to all reforms, genuine and spurious—a sweeping ostracism of the old procedures resulted. The most opprobrious epithets were applied to the obnoxious remedies, and they were denounced as barbarous and harmful under all circumstances. A crusade was waged against calomel, blood-letting, and blistering, which had the effect to deter the timid from their use, and to lead them to accept in their stead the alluring placebos and so-called sustaining remedies now so much in vogue. Disregarding the clamor of the ignorant aud prejudiced, I have used in appropriate cases and at suitable times each of the remedies so persistently maligned, and with excellent results.

In the *Philadelphia Medical Times*, vol. x. page 522, I gave an article on the benefits derived from calomel in certain morbid states; and in the *Medical and Surgical Reporter*, vol. lv. p. 72, one in which venesection was shown to play an important part in averting threatened destruction of life. In the present paper I propose to give a few cases from many which show the inestimable importance of blistering the surface as a curative agency in internal inflammations, whose fatality is fully described by all mortuary records. In the first of the journals named, under the heading of "Catarrhal Pneumonia,"* two cases are related in which the gravest condition was changed for the better most quickly and strikingly.

I refer to the case of Bertie B., 22 months of age, whose respirations before using the blister were 100 per minute, and the pulse 120,—a ratio of ten to twelve. After the production of a blister upon the whole front of the chest, from lines dropped from each armpit, the respirations receded to a range of 72 to 86, while the pulse-rate remained unchanged,—a ratio of seven to twelve. A renewed frequency of respiration on the fourth day thereafter was reduced by extending the blistered surface to the edge of the scapulæ on either side, when the rate of breathing descended to 50 per minute, and continued thereupon to diminish until the natural health-rate was reached. In just a month from the first outbreak as a catarrh the patient was dismissed completely recovered.

The second case was that of Walter H., 13 years of age, recorded in the same paper, and is equally instructive. He had pneumonia as a complication of measles, which commenced April 18, 1883. During the forenoon of Friday, April 20, he coughed almost incessantly. In the afternoon the cough was less, but the fever increased and the respiration became very rapid. At 9.30 A.M., April 21, the rate of the respiration, as reported by the medical attendant, was 60 per minute, varying little during the day. I saw him at 9 P.M. of that day. There were fine crepitant râles in the lower lobe of the right lung, and a few scattered coarse ones in the left. His respiration was 40 per minute, and heaving in character; his pulse 130,—ratio, four to thirteen. The temperature was 104° Fahr. April 22, 11.30 A.M., a full blister, extending across lower part of the breast from scapula to scapula and four inches wide, has been produced. The respirations now number 28, and the pulsations 120,—ratio nearly three to twelve. The crepitation is greatly lessened. At 3 P.M. of the same day the respiration had a further decline to 24 per minute, and the pulsation to 84. April 23, the respiration has risen to 36, and the pulse to 100. There is a crepitant râle of great intensity, dry and crackling, in the whole upper part of the right lung. Upon blistering the whole surface of that side of the chest not already vesicated, the respiration became easier and a moist râle succeeded. The case came to a successful issue under

* Philadelphia Medical Times, vol. xiii. p. 887.

the use of ordinary remedies. It may be proper to state here that neither opium nor quinine, which were freely used, availed to check the advance of the inflammation.

The following cases have never been reported, and are equally valuable as indications of cure:

Lizzie S., infant, was taken March 30, 1885. I saw her on the day following, when she had catarrhal pneumonia fully formed. There were crackling and sibilant râles in both lungs. The respirations were 64, and the pulse 120 per minute,—ratio, one to two. A cantharidal plaster was so placed as to conform to the contour of the whole anterior part of the chest. On the day following the respirations had decreased in a marked degree, and all the symptoms were surprisingly improved. I ceased attendance on the seventh day, the patient having entirely recovered.

Joey B., 1 year old, was taken with distressed breathing and cough March 20, 1887. I saw him at four o'clock P.M. The respirations, because of his uneasiness, were not accurately made out, but appeared to be about 90 per minute; the pulse was about 125. I found a soft cataplasm upon the chest, which was allowed to remain, and quinine sulph. was given alternately with ext. ipecac. fl., ext. jaborandi fl., and tinct. opii.

March 21, 9 A.M. There is no relief to the breathing, which numbers 84 per minute; the pulse is 125,—ratio, two to three. No râle can be detected. Cerate of cantharides was applied to the whole chest, right and left, and the other treatment was continued.

March 22. The plaster caused satisfactory vesication at the expiration of three or four hours. The respiration is less labored, and shows a rate of 72. A faint râle is heard in the left lung. The pulse is 120. Ratio of respiration to pulse, three to five. The bowels have been moved by calomel, the resulting fæces being very offensive.

March 23. A faint râle exists, as at the last examination. Respiration 42, pulse 125,—ratio, one to three.

March 24. All symptoms are favorable,—neither respiration nor pulse being such as to call for special notice. Alvine evacuations are numerous, and remain very offensive.

March 26. The patient still coughs, but is well in other respects. Period of treatment one week.

Mrs. L., a young married woman, was taken with a cold and hoarseness February 16, 1887. At my visit on that day she had a very high fever and general pains throughout the body; the pulse-rate was 140. The treatment was two grains quinine sulphate every two hours, and two grains opium every four hours. She received the same treatment until February 19, when, on account of severe vomiting, she took potassium citrate, creasote-water, and hyoscyamus, but no opium. Her skin was constantly bathed in perspiration, yet there was no remission of the rapidity of the heart's beating. She has been using externally from the commencement a remedy of her own, a tar-plaster.

February 20, 10 A.M. The patient has had a very severe pain during the night, as also a constant cough. The pain occupies the entire area of the left chest from scapula to sternum, and from the axilla to the free border of the ribs. She lies upon the right side, with the left arm close to the affected region, and is unwilling to move either the body or the arm. Early in the morning she commenced to expectorate bloody mucus; the respirations reach 38 per minute, and the pulsations 124,—ratio 1 to 3.3. The skin is moist, the tongue coated, and the stomach quiet. A plaster of cantharides was so placed as to conform to the painful area, and the following medicines were prescribed,—viz., three grains of quinine every two hours, and three grains of opium every six hours.

February 21. The plaster has caused a perfect blister. The patient is free from pain; the skin is moist; the cough and expectoration moderate; the sputa less bloody. The rate of respiration is 22, and pulsation 102,—ratio 1 to 4.7.

February 22. There is a constant sweat, the tongue is cleaner, the expectoration nearly colorless, and there is little pain. The respirations are 20, and the pulsations 96,—ratio 1 to 4.8. She sleeps considerably.

February 25. Respiration 19, pulse 76.

February 26. Took leave, the patient having recovered in eleven days.

The two following cases illustrate most strikingly the necessity of blistering in the cure of some of the inflammations connected with the female reproductive organs.

Mrs. P. is a young married woman, with one child. About the middle of October last, when her menstrual flux had been absent for six weeks or over, at the close of a wearisome day's labor she was taken with hemorrhage from the genitals and a pain referred to the fore part of the thighs, near the knee. The day following the pain shifted to the hypogastric region. After a few days, a discharge having the characteristics of that following abortion succeeded. On the morning of October 30, two weeks from the first attack, she suffered extreme pain and tenderness in the uterine region, and, as she received no relief at the hands of the empiric who had hitherto attended her, I was called to take charge on the evening of that day. At 8.30 P.M. she had extreme pain and tenderness in the hypogastrium, as well as in the fundament, constituting a true tormina. She had also irritable bladder and painful micturition; there was great thirst and dryness of the mouth; the pulsation was small and very frequent,—138 per minute. I

prescribed opium and quinine in large doses: the former to be repeated every four hours, the latter every two hours. A plaster of cantharides was made to cover the entire tender surface. In about three hours I was recalled, as the pain was insupportable, and the other aspects of the disease were still the same. I administered hypodermically a half-grain of morphine acetate; and this, with the opium regularly administered, secured tranquillity for the night.

October 31, 10 A.M. The cerate has caused a thorough blister; the pain and tenderness are greatly relieved; the pulse remains about the same. Evening visit, 8 P.M.: the relief in the abdominal region continues, and the pulse has receded to 122 per minute.

November 1, 10 A.M. Mrs. P. has had an abundant sweat in the night, and the pulse has declined to 102. The quinine and opium were continued as demanded by the fever and pain. On November 2, at 10 A.M., the pulse was at 98; on November 3 it was at 88, a very great sweat having prevailed during the night. There was a tender spot in the left iliac region, to which was applied a blistering plaster three by five inches. On the day following the tenderness was relieved, and the case—one of uterine peritonitis—went on to a rapid recovery, my visits ceasing November 20.

Mrs. H. had what appeared to be an abortion on December 21, 1886, there being pain and hemorrhage from the genitals. On examination no portion of the secundines could be detected in the uterine neck, which was dilated so as easily to admit the finger. Suitable remedies were employed, and the flow seemed to be stanched. The patient, however, failed to do well. There was persistently coated tongue, poor appetite, various pains about the lower limbs, very slight tenderness and pain in the uterus by pressure, with little or no quickening of the pulse. She received various treatment,—quinine, salicylate of sodium, diuretics, and anodynes,—a very great amount of opium being necessary to insure anything like comfort, out of all proportion to the apparent disease. The local treatment consisted of poultices, fomentations, etc., over the uterus, and liniments, vinegar, and flannels to the limbs. By January 17 the pulse, which had been so moderate before, became, notwithstanding the free use of quinine, quite rapid, — 120 per minute. The tenderness, though not acute, was persistent, and there were voided occasional clots of blood. A blister was placed on the hypogastrium, the opium and quinine continued, and, as there was a great sense of weakness and nervousness, the compound fluid extract of cinchona and the fluid extract of cimicifuga were also given, in fifteen-minim doses each. At my next visit, January 18, the tenderness was absent for the first time during her illness, and the pulse had declined to 112. On the day following it receded to 104.

The further record of this case affords nothing other as illustrating the use of blisters, but is valuable as the history of a case in no respect too clear in its indications. During the two following weeks the pulse continued from 95—a very common figure—to 118, the highest. She was also troubled with a nausea and vomiting, particularly at night. By the middle of February the clots, which had been appearing occasionally, were succeeded by a free hemorrhage. Upon an examination by the speculum there was seen to be erosion of the os uteri, which was somewhat dilated and giving vent to blood and mucus. A solution of nitrate of silver (forty grains to the ounce of water) was applied to the whole internal surface of the uterus, which was in a state of involution, and about the os as well. She had been taking for the stomach creasote-water and acid phosphate, the latter of which was now replaced by the extract of ergot,—the prescription reading as follows:

℞ Ext. ergotæ, f℥j;*
Ext. cinchonæ fluid. co.,
Ext. cimicifugæ fluid., āā f℥ss;
Aq. creasoti, f℥ij;
Syrup., f℥ss. M.
S.—Dose, a drachm thrice daily.

She received weekly a topical application of the silver salt, and, continuing the medicines as above, was discharged cured March 15, 1887, after an illness of three months' duration.

CEDARVILLE, NEW JERSEY.

REPORT ON OPHTHALMOLOGY.

BY ALBERT G. HEYL, M.D.,
Ophthalmic Surgeon to the Episcopal Hospital.

(Continued from page 598.)

EYE-INJURY FROM LIGHTNING.

KNIES reports the following. A boy, æt. 10, was struck by lightning while standing at a window. He turned slowly several times round as on an axis, then fell backward to the floor and was unconscious two hours. He recovered consciousness slowly, moving arms and legs. Both eyelids were much swollen, and a great deal of lachrymation existed. Four days later the following was noted: right forehead and temple showed irregularly-shaped scars of

* Increased on March 1 to 3ij.

burns. These extended along the right sterno-cleido-mastoid and the right side of the body to the foot; incomplete ptosis and diffuse corneal clouding of each side; on each side the eyelashes were burned off; right lens showed broad cataractous stripes running from the equator towards the centre, and a large star-shaped post-polar cataract; fundus could not therefore be examined, but there was absolute amaurosis; left eye showed synechia posterior; beginning cataract in broad stripes; eye-ground normal; vision ½, not improved by glasses; on each side the eye-tension much diminished. Two months later the ptosis had disappeared, the corneæ free from clouding, the right lens completely cataractous, light-perception and projection normal. About five weeks later the right eye was atropined, when the lens was noted to be peculiarly round as if swollen. It was removed by simple linear extraction with great difficulty, with the resulting secondary cataract formation, but vision of C. F. at five metres.

Attention is directed to the following points:

1. The incomplete paralysis of the levator palpebræ, inducing ptosis. Why the frontalis muscle was not likewise paralyzed is not clear.

2. The temporary paralysis of the optic nerve may have been due to the direct injury to it from the electricity. Possibly, judging from a case of Laker's, capillary hemorrhage into the nerve would have been seen had the fundus been visible.

3. The formation of the cataract. This is explained as the result of a powerful contraction of the ciliary muscle induced by the lightning.

It is incidentally mentioned that the cataractous stripe of the left eye vanished completely.—*Graefe's Archives*, vol. xxxii.

EPISCLERAL FARADIZATION.

Eulenburg describes an instrument for this purpose consisting of a small platinum plate eight metres long, six metres broad, fastened to a shaft, and capable of being elevated by pressing on a button attached to a handle, and thus breaking the current at will. The instrument, after a previous instillation of cocaine, is applied to the desired spot, while the indifferent electrode may be placed over the sternum. In this way the eye-electrode has been allowed to remain one to two minutes without any injurious effect, even when induction-currents were applied strong enough to induce contraction of the orbicularis palpebrarum or even the frontalis and corrugator. The author was surprised to find, however, that in no case was there any contraction of the eye-muscles, the eyeball apparently remaining perfectly stationary; he explains this on physical grounds, the distinctively watery constitution of the ball diverting the current, and also, in the necessity of the case, the tendon of the muscle and not its belly being mainly reached by the current. As an exploratory method in eye-muscle paralysis there is not much to hope from the method, but in peripheral ophthalmoplegus it promises to be of value.—*Centralblatt f. Augenheilk.*, March, 1887.

[May not the cocaine instillations benumbing the scleral conjunctiva have had something to do with the failure of the eye-muscles to react?—H.]

AMBLYOPIA AFTER QUININE-INTOXICATION.

Patient, a woman, æt. 42, three weeks after a normal and easy confinement, was seized with violent fever, and for about ten minutes delirious: 15.0 (grs.?) quinine were given; three days later sudden amblyopia occurred; the fever continued about a week, and then a general debility ensued, the amblyopia still continuing. In the course of about a couple of weeks symptoms of melancholia developed, which led to her being placed in an asylum. At this time the patient could count fingers at a short distance. The main ophthalmoscopic change was great thinning of the vessels; color of the papilla normal. Under treatment with strychnine, iron, etc., the reason gradually improved, although the papillæ became very pale and the retinal vessels very narrow, the arteries being scarcely visible. Several months later the patient left the asylum well enough mentally to attend to her business, but with defective sight. Both pupils at this time reacted well to light; media clear; papillæ extremely pale; all the vessels extremely pale, especially the arteries; vision about ⅓, not improved by glasses; visual fields defective above and below. Again for some reason the dose of quinine was repeated, and amblyopia again occurred, which for the next seven weeks increased somewhat, then slowly improved, although it was not entirely relieved.—*Klinische Monatsblätter*, February, 1887: reported by Mellinger.

[It will hardly be doubted, after careful examination of this case, that the quinine was only a secondary factor in causing the amblyopia. The points in the case may be summed up thus:

1. Uterine disturbance of some kind after confinement, with consequent derangement of the cerebral circulation.

2. The dose of quinine which aggravated this derangement inducing not only amblyopia, but also the melancholia.

From some experience in the examination of the eyes of cases of melancholia, the reviewer is satisfied that a certain set at least of such cases are accompanied by changes indicating circulatory disturbance in the brain, and probably in the cortex; and, while not prepared to say that these cases of so-called melancholia are simply a species of congestion of the brain, the latter is nevertheless a very important factor. The practical point about the above case is that quinine, at least in decided doses, should be used with care when the uterine vessels are likely to be in an abnormal condition.—H.]

TRANSLATIONS.

TETANUS FOLLOWING THE OPERATION FOR HYDROCELE.—Dr. Rafael Bueno (Havana) reports the following case. Joseph B. V., native of Oviedo, aged 22, single, waiter in hotel, entered La Beneficia Hospital on the 14th of March, 1887, to be operated upon for hydrocele on right side of two years' standing. On the morning of the 15th the operation was performed, a new nickel-plated Galante trocar introduced, which had been previously disinfected in a five-per-cent. phenic-acid solution; a two-per-cent. phenic-acid ointment was also used. The liquid removed amounted to two hundred and fifty grammes. The injected solution, which was a five-per-cent. carbolized solution, came out the color of milk. When the operation had been completed, the patient was attacked with vertigo and mucous vomiting; they quickly disappeared after he was put in bed and given a small glass of sherry wine. He passed the remainder of the day comfortably; the slight pain after the operation disappeared; he partook of broth twice during the day.

For a week after the operation the case progressed satisfactorily and appeared to be rapidly convalescing. On March 22 the invalid breakfasted well, was communicative and lively, though not yet out of the bed. Some difficulty of deglutition became evident at nightfall, and pain was experienced in the ligamentum nuchæ and dorsal region, without any contracture.

March 23, at 3 A.M. Tonic convulsions of the muscles of the back part of the dorsal region; opisthotonos, trismus, dysphagia very noticeable; pulse 108, temperature normal; copious perspiration. Two hypodermic injections of morphine, one and a half centigrammes each, with one hour interval, caused a temporary abatement of symptoms.

At 7 A.M. Trismus, dysphagia, opisthotonos, gastralgia; slight contracture of the muscles of the abdominal walls. Chloral, gr. xxx, and morphine, gr. $\frac{1}{15}$, were given each hour until relief was experienced.

Later, on the 23d, the attacks were repeated at the end of each half-hour; peaceful slumber betweentimes. The muscular contracture had now reached the thoracic cavity. Pulse 108 during seizures, temperature normal; abundant perspiration; urine normal.

At 6 P.M. he vomited a spoonful of chloral, which was taken by great effort, producing an attack, during which seizure the tongue was cut through by the teeth. Respiration was now performed with great difficulty; a cyanotic appearance of the face was noticeable. Discontinued the administration of chloral by the mouth, and ordered three enemata, two grammes each, to be administered during the night, at intervals of two and a half hours.

March 24. The seizures had become more frequent and intense. The respiration was now impeded, the skin assumed a violet hue, the pulse was irregular; enemas of chloral, one gramme each; friction and massage to the thorax and upper part of abdomen. Death at 11.30 A.M., of asphyxia. Removed bandage, and found the little wound wholly cicatrized, without a vestige of suppuration.

The following reflections were made by the reporter:

1. Operated for hydrocele on 15th of March in the morning; used a new trocar (Galante), which had been thoroughly disinfected by a five-per-cent. phenic-acid solution.

2. Nothing remarkable about the oper-

ation, nor in the progress of the inflammation.

3. The man had not left his bed for a single day.

4. Tetanus made its appearance at nightfall on the 22d, and death from asphyxia occurred at 11.30 A.M. on the 24th.

5. He lived in front of a stable, near a car-depot; and, from sources believed to be authentic, there has not been a case of tetanus in this location for three years.

6. La Beneficia has not had a case in fifteen months until this one. He left the hospital to go to festival and work about the tents; this was in December, 1885.

7. There appears to be no attributable cause for the death in this particular case other than the cold humidity which prevailed at that time, and, above all, the great difference of temperature between the night and the day.

8. If tetanus be due to a microbe, it appears to resist a very strong solution of phenic acid (five per cent.), as is shown by this case. — *Crónica Médico-Quirúrgica de la Habana.*

Antipyrin, Antifebrin, and Thallin. —At the Second Congress of Russian Physicians, held at Moscow, Dr. Anserow discussed the comparative value of some new antipyretics: antifebrin, antipyrin, and thallin. All three appear to act upon the vaso-dilators. The peripheral vessels dilate under their influence, and the temperature of the surface rises,—thus equalizing the temperature of the internal organs and the surface, and permitting heat to escape by radiation. The following conclusions are given:

1. Antipyrin, antifebrin, and thallin all act upon the thermo-regulatory apparatus, and produce their effect by dilating the peripheral vessels and augmenting the circulation in these vessels.

2. They act by the intermediary of the central nervous system.

3. They act not only upon the temperature, but also upon the nervous system, in a manner analogous to hydrotherapy.

4. Antipyrin and antifebrin alone deserve to be employed.—*Bull. Gén. de Thérapeutique.*

Liquid Vaseline or Fluid Petrolatum as a Solvent for Cocaine.—Bignon (*Bull. Gén. de Thérapeutique*) advocates a two-per-cent. solution of cocaine in liquid vaseline either as a local application to the eye or for hypodermic use. One drop of this solution will produce complete anæsthesia and dilate the pupil,—dilatation commencing in from thirty-five to forty minutes and disappearing in five or six hours. The accommodation is unaffected even by twice this quantity (gtt. ij of a two-per-cent. solution). A drachm of this may be injected hypodermically as a local anæsthetic for surgical operations, but ordinarily much less will answer if the solution be subsequently allowed to come in contact with the recent incisions during the progress of the operation. The author recommends the use of the alkaloid in this solution in preference to any of its salts, since the latter are difficult to keep and are uncertain in composition.

Antipyrin as an Analgesic.—Germain Sée calls attention to a new and important action of antipyrin. A watery solution containing fifteen grains to the spoonful may be administered at intervals of from one to four hours, giving from three to six grammes (forty-five to ninety grains) at a dose, in ice-water. Given in this way, the pains are relieved without any unpleasant result, especially upon the heart or great vessels. The remedy acts especially upon the spinal cord.—*Revue de Thérapeutique Méd.-Chir.*

Treatment of Chronic Bronchitis in Children.—H. Roger recommends the administration, morning and evening, of one or two granules of sodium arseniate (gr. $\frac{1}{64}$) given in a cup of milk. Before each meal a dessertspoonful of the syrup of the iodide of starch, containing one grain of iodide of potassium in two drachms of the solution. At the meal sixty grammes of raw meat-pulp beaten up with one or two grammes of pulverized calcium phosphate are to be given with other food.—*Revue de Thérapeutique Méd.-Chir.*

Expedient in Obstinate Epistaxis. —Verneuil recommends a blister applied over the liver in the treatment of rebellious epistaxis unaccompanied by fever. He concludes that "(1) latent and still benign diseases of the liver may cause and keep up obstinate epistaxis; (2) the revulsion obtained by the aid of a large blister placed on the right hypochondriac region appears to be the best means of curing hemorrhages of this kind."—*Revue de Thérapeutique Médico-Chirurgicale.*

EDITORIAL.

THE AMERICAN MEDICAL ASSOCIATION.

TWO things were patent to any intelligent observer in attendance upon the Chicago meeting. The first was the magnificent possibilities of such a large and thoroughly representative body of American physicians; the second, the hasty, inefficient, and irregular methods of conducting the work of the general sessions. As at present managed, it appears to be simply an impossibility to ascertain definitely the sense of the Association upon any debatable question. There seems to be no doubt as to the wisdom of the recommendation of the special Committee with regard to the necessity of adopting such a change in the method of selecting the Nominating Committee as will enable it to perform its functions, important as they are, with deliberation and due formality. As an amendment to the Constitution, this will come up for discussion next year at Cincinnati. There seemed to be general regret that it could not go into force at once.

In order that the next meeting shall be distinguished from its immediate predecessors by greater dignity and decorum, the following suggestions are, with due respect, offered to the consideration of the officers, and especially to the Entertainment Committee. In the first place, since all members must pay their dues whether they attend the session or not, let the registration be conducted through the mails prior to the meeting, and the present difficulty in getting registered will be at once avoided. If the lists of delegates were to be sent to the Chairman of the Committee of Arrangements one month before the meeting, he could send by return mail the badge of membership which would enable the wearer to participate in the business of the executive session, and during the course of such executive session no one should be admitted to the floor of the house who is not entitled to be heard or have his vote counted. After the executive session is over, the doors may be thrown open to all who wish to hear the addresses or public discussions. The credentials having been sent in advance, the labor of the Committee on Entertainment will be materially lightened, and invitations to entertainments can be delivered through the post-office, as at present.

A properly-organized Council, in permanent session, would greatly strengthen the Association. There is no need of holding formal meetings, however, with our present telegraph and postal facilities: all its functions can be performed by correspondence or through the Journal as intermediary. It is also a question worth considering whether the provision which prevents permanent members from voting is compatible with the best interests of the Association. In many County Medical Societies the delegates are chosen not because they are the representative members, but because they are new and have never been sent as delegates before. It is true that in this way new members are added every year to the national Association; but it does not seem the height of wisdom to intrust the welfare of the organization to such inexperienced hands, who may fall an easy prey to the medical politician.

Finally, if at the time of registration each delegate were to select one Section with which he desired to connect himself as a member, it would prove advantageous in several ways, and particularly in the election of officers, or in deciding other questions which may call for a vote of the Sections.

THE SPHERE OF THE GENERAL PRACTITIONER.

IN his opening address as President of the recent German Congress of Internal Medicine at Wiesbaden, Professor Leyden discussed in a dignified manner the relations of specialism and general medicine. The scientific specialist, said Leyden in effect, has done much for the advancement of our knowledge of local processes, both physiological and pathological, and of local measures of treatment. The present age is scientific and experimental, and medicine has partaken of the general tendency and has become an experimental science. But the scientific and experimental work in the laboratory, upon which so much weight is placed, and which has unquestionably contributed to exactness in our knowledge, fails to answer the demands of the present, however much it may promise for the future. The living present has claims which the physician must not overlook in his zeal for mathematical exactness in diagnosis and mechanical treatment. It is time to remind the practitioners of our day that the inexhaustible source of all knowledge and progress in medical art is observation at the bedside of the patient. Experiment is one-sided; complete knowledge of disease can be gained only by studying cases.

In the multiplicity of specialties medicine as a whole is in danger of being lost. Internal medicine has itself become in a measure a specialty. The human individual is hardly any longer considered as a concrete whole, as a man. He is an aggregate of organs and cells. Every organ becomes the object of special study and special knowledge. Local examination, local diagnosis, local treatment, is the order of the day.

Against this misleading view Leyden enters a protest. The true function of medical art is not to treat diseases, but to treat persons who are sick. These stricken individuals must be aided in their struggle for existence. This is the duty of the general practitioner. In order to do this intelligently, he must not only be conversant with the nature of the disease-process in certain organs,—for which knowledge he is indebted to the specialist,—but he must also understand and be able to appreciate the influence of the morbid process upon the sick individual. To the cry that general medicine must become more surgical, Leyden returns the answer that the specialties must again become more medical, and thus restore the unity and integrity of general medicine.

"Old truths and old facts are liable to be forgotten," says Leyden, in closing his eloquent address, "and it is not inappropriate to recall them on suitable occasions."

In this paraphrase of the words of one of the leaders of German medical thought we observe a departure from the too exclusively local and experimental methods of the medicine of Germany and Austria during the last thirty years. There is a tendency to return to more philosophical views, such as have dominated French and English medical doctrines, and which have had so large a following in this country.

It is this tendency to which we have striven to give effect in the columns of this journal. While recognizing the importance of specialists and special study, we have always insisted upon the paramount necessity of the combining, unifying, and vivifying influence of the knowledge derived from observation at the sick-bed. The appreciation of the grand truth that "all medicine consists in observation" will restore to general medicine and the general practitioner the pre-eminence they deserve. This will likewise react favorably upon specialism, and the specialist will be, in the words of the lamented Hodgen, "a physician and something more," instead of, as is now too often the case, "something less than a physician."

THE ILLNESS OF THE CROWN PRINCE OF GERMANY.

AS the medical journals have taken up the malady of the Crown Prince of Germany for discussion, we give our readers the following statement from a leading physician of London, who is in a position to be thoroughly acquainted with the facts. It is not a "cablegram," but an extract from a private letter to the Editor:

"The Crown Prince had measles a year or more ago: he caught cold last winter and has been hoarse since. Gerhardt found a small growth on the left vocal cord in March, and the electro-cautery was used with temporary benefit. The hoarseness, however, grew worse and the growth larger while the Crown Prince was at Ems. Bergman, Wegner, and Tobold saw him when he returned to Berlin, and advised thyrotomy. Everything was arranged for the operation, and it was the intention to perform thyrotomy and to be guided by the appearances found, and, if necessary, to perform resection of one-half the larynx. The Crown Princess, however, had been in communication with the Queen, who sent over Dr. Morell Mackenzie. He saw the growth, and stated that he could remove a portion for examination. This he did with intra-laryngeal forceps, tearing away a portion of the vocal cord along with the scrap of growth. The greater part of course remains, the whole having been the size of a split pea, and lying immediately on the under surface of the left vocal cord. Virchow thus had a portion of growth involving its whole thickness, and after examination he said that it was not malignant, and he ought to know, though the general opinion seems to be that the prognosis is very bad."

THE ASSOCIATION OF AMERICAN PHYSICIANS held its Second Annual Meeting at Washington on the 2d and 3d instant. Our report of its proceedings has been forced to lie over until the next issue.

NOTES FROM SPECIAL CORRESPONDENTS.

LONDON.

THE General Medical Council has held another session, the second this year. Sir Henry Acland, who has been its president for thirteen years, retired, and was succeeded by Mr. John Marshall, who a few years ago resigned the chair of Surgery at University College, London. I have already in previous letters mentioned the controversy which has raged all through the past winter anent the Apothecaries' Society of London. The act of Parliament passed last July renders it obligatory upon every student to pass an examination in medicine, surgery, and midwifery before obtaining a license to practise. The Apothecaries' Society had no power to examine in surgery, and consequently, unless the difficulty were overcome in some way, its examinations would cease to have any value. The Society accordingly at first applied to the College of Physicians and Surgeons to admit it to the Conjoint Board; this being refused, it next applied to the General Medical Council to appoint examiners in surgery for it: this the Council did, after discussing the question and a great many side-issues for four days. The curious result flows from this that the despised license of the Apothecaries' Society becomes in a certain sense a state license, because part of its examination will be conducted by examiners appointed by the General Medical Council, which is in reality a Committee of the Privy Council. The licentiates will not be slow to take advantage of this.

The death of Dr. Wilson Fox, Holme Professor of Clinical Medicine in University College, took place on May 3, after a few days' illness. Dr. Fox was a power in the profession by reason not only of the important appointments which he held, but also on account of his upright and generous character: a man sensitive in the point of honor, enthusiastic in every piece of work to which he put his hand, he earned the affection and esteem of colleagues, pupils, and patients by the singular charm of his sympathetic manner and the perfect sincerity of his conduct. Dr. Fox was educated at University College, and became Professor of Pathology there in succession to Sir William Jenner in 1861. For the last twenty years he has been the Professor of Clinical Medicine, and in this capacity every student has passed through his hands. He was a painstaking teacher, who left no point which could elucidate his cases untouched; the care which he taught his pupils to bestow on the smaller details which contribute so much to a patient's comfort was one of the most valuable lessons they learned from him. In early life he gave a great deal of attention to the study of tuberculosis: the view which he consistently held, when it was far from popular,

was that tuberculosis was a special pathological process, to be sharply distinguished from chronic inflammation. An erroneous interpretation of certain experiments on animals, however, led him to believe that the process was not specific: to this is due the non-appearance of his great work on phthisis, for which he had for many years been making preparations. Dr. Fox was a physician-in-ordinary to the queen, and was in the enjoyment of a very large consulting practice as a physician, and, if he had survived, the very highest honors which the profession in England has to give would undoubtedly have been his.

The close resemblance to be traced between certain forms of sarcoma and chronic inflammation has struck many observers, and it has frequently been suggested that some etiological relationship must underlie this anatomical and clinical similarity. A striking instance is afforded by the diffuse sarcomata of the spinal pia mater, of which a few cases are on record. Dr. W. Pasteur recently reported to the Pathological Society two additional examples of this curious disease. The symptoms resemble those produced by chronic spinal meningitis, and in the only case of the kind which I have seen this diagnosis was made by a very eminent neuropathologist: after death the spinal cord is found to be embedded in a mass of sarcomatous tissue which extends the whole length, and completely fills up the space between the bony canal and the cord. The nervous tissue shows no structural changes, except where here and there it is invaded by the new growth; the naked-eye appearances are of course very different from those produced by chronic inflammation, but the microscopical elements have a great resemblance, the fundamental difference being that in the sarcomata there is no tendency towards organization or retrogression. At the last meeting of the same Society a closely-related question was raised by Messrs. Shattock and Ballance, who reported the results of some experiments made with malignant tumors to ascertain whether any vegetable parasites were present. In every case where sufficient precautions were taken to exclude contamination by material on the surface of the growth exposed to the air, where of course micro-organisms swarm, the tubes inoculated with the portions of tumor remained quite sterile. The experimenters, however, were by no means inclined to abandon the parasitic theory of the origin of malignant growths on account of these negative results: their view appeared to be that the parasite was probably not surrounded by proper conditions for culture or had become devitalized.

Headache is one of those smaller evils which sometimes make existence almost intolerable, and yet it must be confessed that remarkably little help in its treatment is to be derived from a perusal of text-books or encyclopædias: that it is generally symptomatic will be universally admitted, but ignorance of ultimate causes is still so complete for a large proportion of cases that a paper communicated to the Royal Medical and Chirurgical Society by Dr. Alexander Haig will be read with interest. He seems to have well worked out the relation of a certain form of headache, which may be called the gouty headache, to the excretion of uric acid. The headache could be brought on by eating meat and cheese, and he found that there was retention of uric acid before the headache, excessive excretion during the headache, and diminished excretion after the headache. Whether there is merely retention or also excessive formation would be an interesting point to determine, but this could not be ascertained. The amount secreted during the headache was greatly in excess, and more than accounted for the retention which occurred during the headache, but the amount excreted after the headache was diminished, and the diminution before and after just balanced the excess during the headache. Dr. Haig thinks that there is temporary excessive formation, and that this accounts for the good effects of salicylate of soda, which diminishes the formation of uric acid; a meal also has a good effect by increasing the alkalescence of the blood. This last observation appears to be of special interest, because it appears to be a general custom to attribute headaches which are relieved by food to "cerebral exhaustion" or "neurasthenia."

Very conflicting accounts are to be heard and read of the value of Dr. Bergeon's treatment of phthisis by the injection of sulphuretted hydrogen into the rectum, and this although the process has not been very extensively used. One physician will say that it is the greatest advance ever made in pulmonary therapeutics, another that it does no good, and a third that the slight amount of benefit does not compensate for the disagreeableness of the operation. The eccentricity of the method, so to say, repels many, but the theory upon which it is founded is ingenious, and nobody seems to be inclined to dispute the main fact upon which it rests,—namely, that sulphuretted hydrogen and carbonic acid in the intestines are carried away by the portal circulation and immediately excreted by the lungs.

At the last meeting of the Ophthalmological Society, Mr. Lang advocated the insertion of an artificial globe into Tenon's capsule, after excising the eye, as a substitute for Dr. Miles's operation of evisceration, with insertion of an artificial vitreous. The operation was originally suggested by Mr. Adams Frost at the Brighton meeting of the British Medical Association last year. The globe is enucleated, the four recti are then held apart, a glass sphere is introduced into Tenon's capsule, and the tendons, capsule, and conjunctiva are united over it. Mr. Lang reported that suppuration had not occurred in any of the six-

teen cases in which he had performed the operation: this he attributed to the antiseptic precautions used,—that is to say, irrigation before and after excision and at the end of the operation.

Dr. Lewers has reported to the Obstetrical Society the condition of the pelvic organs in one hundred cases, as nearly as possible consecutive, of women whose bodies were examined after death at the London Hospital. Disease of the Fallopian tubes, restricting the expression to pyosalpinx, hæmatosalpinx, and hydrosalpinx, was met with in seventeen out of the one hundred cases examined. Dr. Galatin stated that the proportion was much smaller at Guy's Hospital. It had been found there that in three hundred and two cases there were of chronic inflammatory disease about the tubes nine per cent., distention of tubes four per cent., and that death could be indirectly traced to pelvic inflammation in about two or three per cent. It ought to be added that fourteen out of the seventeen cases observed by Dr. Lewers were women over forty years of age, whereas the majority of the women upon whom Mr. Lawson Tait has operated have been twenty-seven or thirty years of age.

The medical staff at Guy's Hospital has been depleted so much during the last few years that it became necessary for the Governors to take some decisive step to bring it up to its full strength. Vacancies for two or three assistant-physicians were accordingly declared, and physicians unconnected with Guy's were invited to apply; no less than twelve applied, in addition to two physicians connected with Guy's; both of these latter—namely, Dr. G. N. Pitt, the Medical Registrar, and Dr. L. C. Wooldridge, the teacher of practical physiology—were appointed, and one outsider was chosen; the fortunate candidate was Mr. E. C. Perry, who had recently taken his degree in medicine at Cambridge, after studying at the London Hospital; he was selected probably because he was Senior Classic in 1880.

At St. Thomas's Hospital also two appointments have been made, both Dr. W. B. Hadden and Dr. Theodore Dyke Acland having been appointed assistant-physicians; both are already well known, the first as a neurologist and the second chiefly for his bacteriological researches.

Owing to the death of Dr. Wilson Fox, Sir William Gull becomes physician-in-ordinary to the queen, and Dr. James Reid, who has been for some years the resident medical attendant on the queen, has been appointed a physician-extraordinary.

DAWSON WILLIAMS.

THE Legislature of Pennsylvania has given twenty-five thousand dollars to the Medico-Chirurgical Hospital of Philadelphia.

BOSTON.

THE Massachusetts Medical Society held its One Hundred and Sixth Annual Meeting in Boston, June 7 and 8, with an attendance and interest fully up to the average. The total membership is now sixteen hundred and sixty-one, ninety-five new members having joined in the last year, and twenty-six having died. As usual, the Massachusetts General and Boston City Hospitals were thrown open to visitors, and operations were performed in the amphitheatre. At the latter hospital there were several capital operations. The programme of the meeting on Tuesday, the 7th, included papers on "Tumors of the Bladder," by Dr. George W. Davis, of Holyoke; "Cases of Burns, with Special Reference to Complications, Sequelæ, and Treatment," by Dr. J. E. Cleaves, of Medford; "Laparotomy for Pus in the Abdominal Cavity, and for Peritonitis," by Dr. John C. Irish, of Lowell; "Fracture of the Spine: its Immediate Treatment by Rectification of the Deformity and Fixation by Plaster-of-Paris Jacket," by Dr. H. L. Burrell, of Boston; "Observations on the Puerperal Pelvic Ligaments," by Dr. S. W. Driver, of Cambridge; "The Relation of Tea-Drinking to Disorders of the Nervous System," by Dr. W. N. Bullard, of Boston; "Pulmonary Tuberculosis as a Sequel to Ordinary Pleurisy with Effusion," by Dr. H. F. Vickery, of Boston; and "The Surgical Treatment of Empyema," by Dr. M. H. Richardson, of Boston. At the meeting on Wednesday other papers were read, on "A Contribution to the Study of the Etiology of the Summer Diarrhœa of Infants," by Dr. H. C. Haven, of Boston; "Sepsis and Antisepsis in Summer Diarrhœa," by Dr. S. A. Potter, of Roxbury; "Training Nurses," by Dr. Alfred Worcester, of Waltham; and "The Value of Public Health Measures to the State," by Dr. S. W. Abbott, Secretary of the Massachusetts State Board of Health.

The paper of Dr. Abbott was one of marked interest, being based largely on data gathered and compiled by the writer in his official capacity. The decrease in the mortality from the so-called preventible diseases in the years since sanitary science has been practised in the cities and towns of this State was strikingly shown in the case of typhoid fever, cholera, and smallpox, but not in diphtheria, which seems on the whole to be upon the increase, as are also developmental diseases like cancer and some local affections. The increase of the average age of the population at death during the last decade was shown by charts to be actual, but not great, for every class in the community.

At the conclusion of Dr. Abbott's paper a discussion was opened by Dr. Henry I. Bowditch, one of the original members of our State Health Board, who spoke with great earnestness on the subject, particularly with reference to the duty of the State towards the

physical training of the pupils in our schools. He deplored the present lack of attention to this important subject on the part of educators. The military drill, the only attempt towards meeting this requirement in Boston and many other cities, was characterized as inadequate, if not positively harmful. Dr. Bowditch had lately seen a West Point cadet with one shoulder lower than the other, and it is well known that there the most careful gymnastic training is given to overcome the defects and dangers of this one-sided and at best cramped exercise.

Other speakers followed in the same strain. One had seen two deaths from phthisis in young women who had gone to teach in a school-house which, after proving the source of much sickness, was found to have had all the time some eighteen inches of water in its cellar.

A committee of three was appointed to investigate the general subject of physical training in public schools, with special reference to what has been successfully done elsewhere in this matter, and to report at a future meeting a plan feasible and adapted to the needs of children of both sexes. The recommendations of this committee are, it is understood, to be laid before the State Board of Education, with whatever of influence the weight of the Society may bring to bear.

The Annual Address was delivered by Dr. George J. Townsend, of Natick, on "The Massachusetts Medical Society: its Relations to Medical Progress and to the Community in which we practise." It showed the true function of a medical society, and vindicated the profession from the charge of sectarianism in medicine, showing that the regular physician was not a "-path" of any kind, and did not belong to any "school," least of all to an "old school."

The members of the Society then sat down to their annual dinner, which was presided over by Dr. William L. Richardson, of the Harvard Medical School. Speeches were made by the President of the Society, Dr. Thomas H. Gage, of Worcester, His Excellency Governor Ames, Hon. George M. Stearns, United States District Attorney, Rev. Brooke Hereford, Professor J. P. Reynolds, Colonel T. W. Higginson, Roger Wolcott, on behalf of the Trustees of the Massachusetts General Hospital, Mr. Hodgson, of the English Society for Psychical Research, and others.

Dr. J. S. Billings, of Washington, delivered a course of lectures on "The History of Medicine" before the students of the Harvard Medical School during the spring. The course was attended by many physicians as well as students, and was found to be of much interest. Dr. Billings also gave two lectures while here to the students of the Massachusetts Institute of Technology. It is reported that the same gentleman may be heard here again next winter in a course before the Lowell Institute, which is one of our most valuable institutions, having an income sufficient to pay liberally for several lecture-courses during each winter from men the most competent in the world to speak on their several departments of knowledge.

The Washingtonian Home, a most valuable institution for the care and cure of inebriety, under the charge of Dr. Albert Day, has just made its report for the current year, showing three hundred and seventy-nine patients treated, at a cost of $12,240.07. This sum was met in great part by payments from the patients, many of whom are men in fair standing socially and financially, who, finding themselves in danger, voluntarily put themselves where for a time they will be removed from temptation, or where they can be sure of good treatment and secrecy while recovering from the effects of a debauch. There were during the year ninety-nine cases of delirium tremens, with only one death. About three-fifths of the patients were married men, and nearly all were residents of this State.

C. F. W.

THE GERMAN CONGRESS OF PHYSICIANS.

(Continued from page 605.)

PROFESSOR LITTEN, of Berlin, contributed a paper on the subject of the *Connection between Disease of the Stomach and Change of Position of Right Kidney.*

The fact that distention of the stomach (ectasia) occurs in connection with dislocation of the kidneys, the so-called wandering kidneys, is not new. The only question is if this stands in a causative relation with the other. The change of position of the kidneys is dependent on mechanical causes; in women it is often occasioned by too tight lacing. The speaker then related such cases of dislocation as had not yet appeared in literature. He has made the observation that the ectasia of the stomach occurs frequently in connection with dislocation of the kidneys in laborers, masons, railroad and street navvies, whose mid-day meals often consist of indigestible food, are eaten in a very short time, —in fact, devoured without form. He also found two women among his patients who were able to take their meals quietly. Out of twenty-six cases of stomach-distention observed by him, in seventeen dislocation of the kidney was present; this brought him to the belief that the stomach-distention is the cause of the dislocation of the kidneys. In the other cases the renal arteries are probably too short, so that on this account the kidney cannot escape. The greater or less movability of the kidneys depends upon the more or less tightness of the arteries. In closing, the speaker went into detail concerning

his findings in post-mortems of such persons as had distention of the stomach with wandering kidneys.

Professor Nothnagel, of Vienna, opened the discussion. He was acquainted with the frequent coincidence between distention of the stomach and dislocation of the kidney, but disputed, however, the causative connection. He had in a period of three months found sixteen such cases. The stomach-distention in many instances was primary, the dislocation of the kidney secondary. He did not know, however, if stomach-insufficiency was able to cause movements of the kidney. The greater number of dislocations occur in broken-down, nervous women. The speaker would like to point out the first case where dislocation occurred, then distention. He reported a dislocation of the kidney of a remarkably high degree. He then dealt with the treatment of this disease. He placed lean persons first on the malt cure, then placed a cushion over the kidney to hold it in position, and a waist over the cushion which covered the whole body.

The Cure of Neuralgia by means of Cataphoresis.—Professor Adamkiewicz, of Cracow, read on this subject. The reader had already in a former article expressed the opinion that by means of an instrument devised by himself, and called "diffusion electrode," chloroform could be put through the skin of a man until he was thrown into the deepest cataphoresis. He then reported the results obtained by this proceeding in the treatment of neuralgia. The diffusion electrode should be connected with the positive pole of a constant battery, and without current placed upon the painful part. Now the current should be closed, and gradually increased to seven M.a. It should be held at this height for two minutes, then slowly brought down to nothing. From this kind of an application the speaker had never seen any evil consequences. He had never observed the formation of eschars, but had found that cataphoresis cured the neuralgia in all his cases, and that the cure followed more promptly the more recent the case. The nerves having a superficial course he found could be cured much easier when the conditions were favorable. Four, indeed one sitting may be enough to completely remove the complaint. In chronic neuralgia the cataphoresis cure shortens the duration of the attack, weakens its intensity, and can for a longer or shorter time bring it under control. Those neuralgias which depend on a lesion which cannot be reached by the cataphoresis are very unfavorable for its definite action.

Professor W. Lowenthal, of Lausanne, and Docent Rumpt, of Bonn, took part in the discussion. The last made a few objections, but was not prepared to change the results of the essayist's exact investigations and good observations.

The Etiology of Typhus.—Professor A. Fraenkel, of Berlin, made an address on this subject. This was discussed for a short period with considerable vigor. The discussion was concerning the infectiousness of the disease.

Professor Finkler, of Bonn, read a paper on *Observations on the Mode of Contagion and Treatment of Typhus Abdominalis* (*Typhoid*).

Among the purely contagious diseases are smallpox, scarlet fever, and diphtheria. A pure miasmatic disease is represented by malaria. Between these two we now place a third class, termed contagio miasmatica, to which we refer cholera and typhus abdominalis. It is partly believed that typhoid is not carried directly, but the germ coming from a diseased person attains a certain ripeness in the soil, then is able to generate the disease in another person. The knowledge of the quality of bacteria, and especially of those which would seem to be the generators of typhoid, goes to show that this indirect spreading does occur. It appears that this is the rule, and direct infection is entirely denied by many. Recent observations prove the infection is carried by many different kinds of vehicles. An excellent example is the epidemic in Mayence in 1884, which was undoubtedly carried by artificial mineral water (according to Dr. Helwig); also an epidemic in Cologne which was carried by means of milk from a certain infected dairy; also the epidemic in Triberg, Black Forest, from the water of a certain brook. All these epidemics are proofs of this kind of contagion, and it has been very difficult to bring proofs of a direct contagion. Again, it is true that different epidemics possess different forms of contagiousness. In 1885–86, a severe epidemic took place in Bonn. A woman went to Eisel and attended her children who were ill with typhoid. After their recovery she returned to Dollendorf on the Rhine, and fell ill with the disease herself. She gave it to the woman who attended her, and so on, until in nine months fifty cases occurred among the fifteen hundred inhabitants of the town. The spreading did not seem to take place by means of the water which flowed through the village, but through the mingling of people together. Three patients from Dollendorf were taken to the Klinik at Bonn, and started an epidemic there. Here the infection was quite direct, partly through the washing (one out of three washerwomen took the disease). On the other side, the sisters, by taking a child ill with typhoid from a damp house to Königswinter, carried an epidemic there into the hospital among the nurses and sisters, which, however, was soon over, but broke out again with great severity eight months later from the opening of a dung-hill into which mattresses, etc., from the patients' beds had been thrown. The germ by remaining in the soil can take on virulence and hold its life for a long time. Typhoid is not confined to certain parts of the earth; it can be carried into a city like Wiesbaden, otherwise

so favored as to health, and disturb this security. From numerous examples we know that if the nest in which the germs are resting is destroyed the epidemic will be cut off for all time; and from this fact it must be believed that there is a difference between the medium which spreads the disease and the source of infection.

Professor Fleischer, of Erlangen, gave experimental contributions on the pathology of the kidneys. They consisted of numerous experiments on a dog.

Dr. Kuhne, of Wiesbaden, read a treatise on the appearance of the spiro-æchten form of the comma bacillus of Koch in the tissue of the intestine in cases of cholera, with demonstrations of different fluorescent preparations. The speaker had examined a great many specimens from the epidemics of Paris and Palermo when he accidentally came upon this variety. After discussing the comma bacillus *in extenso*, he closed by recommending his method of coloring to find the bacillus in the tissue. He then gave different methods of his own to bring to view the bacillus in the internal organs in typhus, lepra molleus, etc.

Dr. Fränkel, of Dornheim, read on *The Permanent Inhalation of Fresh Air*, a treatise on the prophylaxis and therapy of lung-affections.

Professor Von Moring, of Strasburg, read on diabetes mellitus, on which disease he is a well known authority. He related how he had given a dog diabetes mellitus by means of phloridizine, and gave some excellent observations, which he was well able to make.

Professor Leube, of Würzburg, thanked the reader heartily for his most excellent paper, and hoped the dark subject of diabetes mellitus would now be brighter.

Dr. Cahn, of Strasburg, spoke on the acids in carcinomatous stomachs. This was followed by an earnest discussion, taken part in by Professor Riegel, of Giessen, Professor Fleischer, of Erlangen, Professor Von Noorden, of Giessen, Professor Von Mering, of Strasburg, and Dr. Stuckel, of Cologne.

Professor Leyden, from the chair, asked for themes for the next Congress, and gave the information that Professor Fürbringer, of Berlin, would offer a paper on the subject of the treatment of abdominal typhus. Professor Binz, of Bonn, would read on the subject The Application of the Spiritus Vini in Therapeutics. The secretary, Dr. Emil Pfeiffer, of Wiesbaden, read the reports of the various committees, saying that the executive committee had chosen Wiesbaden as the place of the next meeting. The number of members at the last meeting was two hundred and nine, died seven, leaving two hundred and two at the beginning of this Congress. Twenty-three new members were added, making two hundred and twenty-four, an increase of fifteen. The number of these present at the Congress last year was two hundred and thirty-four, this year two hundred and forty-nine.

Professor Franz Liebenstein read on the subject Muscular Exercise or Quiet for Heart-Disease. After enforcing that proverb of Professor Hoffman's, forbearance and exercise, the reporter said that the majority of the clinicians and physicians held out firmly against a more active treatment of chronic heart-disease through exercise of the heart-muscles, and insisted that above all things all acute cases, also those where an over-distention of the heart had occurred, must be handled with care. Quiet does not, however, improve the chances of the patient, while a reasonable nourishment combined with exercise properly carried out causes a strengthening of the heart-muscles. In all chronic cases we should change from quiet and care to the endeavor to strengthen the heart-muscles by exercise. From his rich experience the reporter felt sure strong yet quiet movements, with quiet exhalations of air, work towards strengthening and slowing the activity of the heart, as has already been made known by Schott, of Rauheim. In cases where the kind of failure is that of performing the work required in complete contraction, the distended ventricle is never entirely emptied, and the heart-muscles become weary and in the end incapable of performing their duty. Then by means of quiet but energetic muscular exercise the heart is strengthened, stirred up to effectual contraction, and at the same time the diastole grows in consequence of the slowing of the pulse. The increase of the arterial blood-pressure acts on the vagus centre, more of the distended blood is forced out of the heart, and thereby the cause of the dilatation removed. Further, the rapidity of the blood-stream increases in consequence of the increase of the arterial pressure. Then after a number of strong contractions this acceleration goes through the capillaries and the veins, and a better distribution of blood takes place throughout the entire vascular system. The improvement in the quality of blood lightens the work of the heart-muscles, and in consequence of the stronger stream in the coronary arteries the weakening remaining products are more promptly removed. For patients in the first stages of fatty heart, or with well-compensated heart-failures, every form of German or Swiss gymnastic or mountain-climbing can be recommended. The speaker warned his listeners against over-exertion, and said that each performance should be followed by a sufficient period of repose. Those failures, however, which have no compensation or have lost it must first pass through a period of quiet and forbearance, then by well-measured work commence to improve the activity of the heart. The watchful control of the physician is necessary, and only the most quiet forms of muscular labor are fitting. The Swedish method

improved by Schott, brief and under medical control, interspersed with pauses for quiet, is to be recommended. On the ground of his experience of the last few years, the speaker advised the Oertel cure for chlorotics, but above all things with the greatest care and not to leave it to the patient himself. The heart should not be allowed to be more rapid in its actions than the lungs can follow, for deep, quiet breathing has a lightening influence. He closed with the wish that the therapy of chronic heart-disease would be placed on the list of subjects for discussion in the Congress.

Dr. Theodore Schott, of Bad Neuheim, recalled the fact that his brother, now dead, had recommended strong but quietly-carried-out movements with regular breathing as a method of cure in chronic heart-disease. The mountain-climbing method of Oertel the speaker could not sanction. It is useful only for a very small number of patients; we cannot say when we may commence with this treatment, or how high or far the patient shall be allowed to climb. There is always decided danger connected with this plan of mountain-climbing, and the doctor had seen harm done to patients treated in this manner by Oertel and his disciples. It is better far to first strengthen the heart-muscles by means of baths, gymnastics, etc., so that it can stand the greater labor required for mountain-climbing. In other cases the danger incurred by climbing is too great, but this can be determined by the pulse-rate.

Professor Leyden, of Berlin, remarked that the mode of treatment originated by Oertel had given valuable therapeutic material and was also an advance. He advised great care in deciding which cases of heart-disease could be improved by the gymnastics and when it is to be used. For light cases in youth, in which a valvular insufficiency can be compensated, careful gymnastics may be used. The President then recalled the fact that the method of Stokes had met with great objections, and was of the opinion that in the very difficult question, what influence movements, gymnastics, and mountain-climbing have on the heart, the deductions are still arbitrary in many points. He closed with the expression of the hope that in one of the Congresses not far in the future there would be sufficient material on hand to explain this weighty and difficult chapter.

Professor Schultze, of Heidelberg, reported numerous cases of acute disease of the central nerve system in which the general anatomical changes fail and we must decide on a diagnosis of meningitis.

Professor Friedrich Mueller, of Berlin, read on the resorption of food in certain diseases.

Professor Leyden then made a few short closing remarks, in which he expressed great satisfaction with the work of the Congress and hope for its future advancement.

Adjourned to meet in Wiesbaden a year hence.

PROCEEDINGS OF SOCIETIES.

AMERICAN MEDICAL ASSOCIATION.

IN accordance with the programme, the Thirty-Eighth Annual Meeting of the Association convened in Chicago at 11 A.M., June 7. As usual, it continued four days; its general sessions occupying each morning, while the several Sections devoted the afternoons to their proper work, except the final afternoon, which was appropriated to a visit to the city of Pullman. The evenings were filled very agreeably by the Entertainment Committee with numerous receptions at private houses of the leading citizens, both physicians and laymen, a general reception being given on the evening of the second day by the profession of Chicago, at the armory of Battery D, on Michigan Avenue. The general sessions were held in Central Music Hall, which was convenient, comfortable, and well adapted to the purpose. On the contrary, the places appointed for the various Sections were widely separated, giving rise to considerable inconvenience and causing a reduction in the attendance upon their meetings. There was no lack of papers, and those read were fully up to the standard of former sessions, and many of them were such as to reflect credit upon American medicine. The number of delegates and permanent members in attendance was about twelve hundred. No serious differences of opinion were brought out in the discussions; evidently the enemies of the International Medical Congress had concluded to contribute to the harmony of the meeting by remaining at home.

Among the features of the session were the daily issues of the *Medical Standard* and the *Medical Journal and Examiner*, each of which published interesting reports of the work of the Association of the day preceding. These were distributed gratis to the members each morning. This is an instance of enterprise highly creditable to the editors, and in keeping with the energetic and progressive spirit of the place.

First Day's Proceedings.

Dr. Charles Gilman Smith, the genial Chairman of the Committee of Arrangements, called the meeting to order, and the session was formally opened by prayer by the Rev. S. J. McPherson. Dr. Smith then introduced the Mayor of Chicago, Hon. J. A. Roche, who delivered a brief address of welcome. The report of the Committee of Arrangements was read and adopted. Ex-Presidents and Vice-Presidents of the Association were requested to find seats upon the platform, and, as they did so, were greeted with applause.

Dr. P. H. Millard, Vice-President, of Stillwater, Minnesota, was called to the chair by

the President, E. H. Gregory, M.D., of St. Louis, Missouri, who proceeded to deliver

THE ANNUAL ADDRESS OF THE PRESIDENT.

"Cell-Antagonism" had been selected as the principal subject of the Address. In the mind of the speaker, cell-antagonism is life. It forms "the foundation of symptomatology and pathology; conjoined with cell-changes, the basis of pathological anatomy, embracing at once the universe of life and all the possibilities of life, disease being but one of the multitudinous phases of life." In the cells resides the force of "vital resistance" which forms the basis of therapeutics,—the real *vis medicatrix naturæ*.

In pathology, organizable fluids are no longer recognized. Cell-potency, cell-subtlety, and cell-antagonism constitute the pith and marrow of medical science. Inflammation is practically a struggle between irritant bodies and white blood-corpuscles. Where pus is found, it is the result of the intrusion of some noxious agency, some contagion, some pestilence: in short, a specific cause, a bacterial invasion.

Cell-antagonism implies a struggle. The duration of the struggle is determined by the quality of the irritant and the strength and resources of the antagonists. Acute inflammation is a sharp and decisive action; chronic inflammation is slow and indefinite. There are two striking important chronic conditions: the interstitial inflammation and the infective granulomata,—interesting alike to the physician and the surgeon. Both are alike disastrous: interstitial inflammation destroying by cicatricial contraction, infective granulomata by stopping at the fibroblast stage,—retrogression replacing development. The quality of infection and the failure to develop beyond the stage of granulative tissue is the exact condition as illustrated by tuberculosis, syphilis, lupus, etc., in contrast with which is fibrosis of the liver, cirrhosis, fibrosis of the kidney, Bright's disease, fibrosis of the brain, sclerosis, interstitial inflammation destroying the tissue-elements by strangulation, and infective granulomata by contamination.

Again, the two varieties of inflammation referred to declare that the quality of the irritant determines the effect of the inflammation,—the interstitial variety being caused by physical agency, and the infective by a vital one. Cells antagonize physical causes without losing any of their vital qualities. Not so when cells antagonize vital causes. When cells are pitted against cells they may be despoiled of their highest quality, as in the infection granulomata they have parted with formative activity. In short, the knowledge that pertains to the presence of a vital irritant epitomizes all that has been taught of infective disorders. The symptomatology and pathology of this class of diseases is but the life-history, the play of cell-activities, metabolisms, and catalyses of antagonizing organisms; likewise the knowledge pertaining to the presence of a foreign body or physical irritant is the knowledge in brief of fibroses and in general of the entire class of disorders known as interstitial inflammation. A persistent irritant—injury—with its attendant concentration of leucocytes, their inevitable development and ultimate transformation, the history of the capsulation of a foreign body, whether it be animate or inanimate, is the history of cirrhosis of the liver, fibrosis of the lung, morbus Brightii, atrophy of the heart, atrophy of voluntary muscles in general, sclerosis of the brain and bones: in short, diffuse capsulation. Some disseminated irritant, say alcohol, determines a sclerosis of the liver, and how? Every particle of alcohol being a foreign particle, having its capsule, it follows that capsulation is as uniformly distributed as the cause. An artisan inhales fine particles of steel or other foreign material, and fibrinosis of the lung is the consequence. The irritants of gout and rheumatism are lodged in the kidney, the interstitial tissue of the organ increases, and in the end strangulates the tubules and Malpighian bodies, resulting in shrinking and total disorganization of the organ, constituting Bright's disease. Like changes occur in the heart coincident with the development of the interstital fibrous tissue, as atrophy of the muscular substance, substituting a fibrous induration for its normal structure. A similar change in the voluntary muscles occurs in the curious disease known as pseudo-hypertrophic paralysis, chiefly afflicting children. The connective tissue between the muscular fibres increases so much that the muscles affected may exceed their normal size three times. Later, however, the new tissue shrinks, and the contractile material of the muscles is spoiled. The condition of sclerosis in bones corresponds to cirrhosis of the liver and Bright's disease of the kidney. In the nerve-centres the interstitial tissue — neuroglia — takes on the same chronic over-growth, strangling the nerve-strands and cells, giving rise to the most singular and complicated nervous phenomena. The changes thus induced are recognized by the general term sclerosis. If it involve the fascicules of Burdach and the column of Goll, locomotor ataxia results; if the medulla, bulbar paralysis, etc.

He had purposely avoided reference to diathesis, as also to the precise neurological relationship of cells, not because he denied their influence, but because too little is definitely known. On the contrary, the behavior of cells relatively to irritants is well understood. The presence of a foreign body is at once and directly resisted by the leucocytes, a zone of inflammation, its destruction, transportation, or capsulation; even parasites which resist the death-dealing assaults of the

leucocytes are at last imprisoned in cases of fibrous tissue.

There yet remains for our consideration a mysterious possibility relating to cell-life of great practical moment: that of entering upon a life of independence, separating from the central nervous system "head-quarters," disregarding the "field-telegraph," oblivious to the morning "drum-beat," and wholly ignoring the restraining and directing influence of environing structures. We have learned that however much irritation may affect the vital qualities of cells, their fidelity is always preserved, there being no sign of disaffection, the army ever intact, the fealty of the soldiers supreme. Physical causes—traumatism—may crush or impair the tissues, but the cells come to the rescue with all vigor and directness. The prolonged presence of bacteria may impair the forces of the cells, enfeeble and extinguish them, but as long as life lasts their efforts are in harmony with the purposes of the organism. Thus it appears that alienation is not possible through the agency of irritation, however intensified, modified, or prolonged.

The question constantly obtrudes, Is alienation possible to a mature element, to an element that has assimilated itself physiologically as well as anatomically with the surrounding tissues, taking part in its functions, concurring and co-operating in all the processes of the economy? This question seems to have confronted Cohnheim when his ingenuity suggested the embryonal hypothesis,—viz., that the tumor-germ was congenital; that there were in the mature body embryonal elements and tissues not utilized in the elaboration of the normal structures: latent embryonal elements, small embryonal cells so diminutive as to elude observation, inactive perhaps till some exciting cause awakens activity. Is not an embryonic element in a mature organism an alien? Is it not already an independent element? Are not the patches in the skin, pigmented moles, islands of cartilage in mature bone, congenital angioma, etc., independent structures, already tumor-germs, congenital rudiments of tumors? Accept the hypothesis of the great German pathologist, and the problem of tumor-etiology is almost solved; it remains only to find the exciting cause; the predisposition is inherited; irritation, simple or otherwise, may be nearly allied to the awakening impulse. The difficulty is to reconcile cell-antagonism with the proposition this doctrine includes: the idea that all discordant bodies are treated as intruders, either ingested, transported, or covered up. We can conceive the possibility of the existence of an inoffensive tissue or element, one that simply draws its nourishment from adjacent tissue without any serious disturbance of their normal metabolism. We would gladly adopt the theory of Cohnheim which ascribes the origin of tumor-neoplasms to persistent germinal rudiment. Certainly it has much to recommend it. Countless latent embryonal structures, relatively independent, are tolerated by the organism, remaining inactive till favored by some concurrent event, the nature of which is incomprehensible, when they may grow according to their bent. Is it not quite as possible there may be similar, relatively independent elements ready, when stimulated, to multiply independently? Congenital angioma often grow without definite limit; pigmented moles—black, slightly-raised patches in the skin with which all are familiar—are composed of tissue exactly resembling sarcoma; always suspicious because of their disposition to proliferate independently. It is most difficult to believe in the infidelity of covenant cells of sundering the compact which unifies the organism. Emancipation seems almost out of the question. We must not only believe that dependent benignant elements become independent, but indifferent, vicious, infective. In short, the elements of the host become the elements of a parasite,—a parasite so vigorous, corrupt, and wicked as to destroy its source.

The painful part of the retrospect of a year is that which recalls those who have been taken from us. The past year has had a very special grief for our Association in the death of one of our ex-Presidents, Dr. William Owen Baldwin, who died at his residence and the place of his birth, Montgomery, Alabama, May 30, 1886. He was among the early members of the American Medical Association, and its President in 1869, presiding at New Orleans. His address on that occasion will be remembered as abounding in Christian and patriotic sentiments, eminently befitting the good and great physician. The Committee charged with the organization of the Ninth International Medical Congress, which meets at Washington City this year, had named him as one of its Vice-Presidents. Dr. Baldwin was remarkable for his culture, the eloquence of his speech, and the beauty of his diction, and will be remembered as an imposing figure in the history of this great Association.

I need scarcely remind you, gentlemen, that we shall have with us after a few weeks the medical men of all nations. Soon we shall extend the hand of fellowship to those with whom we have heretofore been united in interest and sympathy in the cause of science. We know that everything is being made ready, and that success is assured. Again you will join me, I know, in the declaration that a hearty American welcome awaits their advent, and that the ninth meeting of the great Congress will be memorable in the history of its organization.

On motion of William H. Pancoast, M.D., of Philadelphia, a vote of thanks was unanimously passed to the President for his most interesting and suggestive address.

By permission of the Association, the report of the committee on "The Sanitation of Emigrant-Ships," appointed at the last meeting, was read by the chairman, Dr. A. N. Bell, of New York. The report directed attention to the inefficiency of present legislation in securing proper sanitation on board of emigrant-ships, and pointed out some flagrant abuses. Among the means to be adopted, it was recommended that Congress be memorialized upon the subject by the Association, recommending that all vessels carrying more than six hundred passengers and crew, other than first-cabin and saloon passengers, should be provided not only with a properly-qualified physician, but also with a junior or assistant. These should all be competent to render prompt medical aid without charge to those who may need it, and also be capable of making suggestions to the master upon the sanitation of the vessel, and on arrival shall make full reports to the sanitary authorities of all cases of disease, insanity, or imbecility occurring during the voyage. An amendment to the Medical Act of 1882 was deemed imperatively necessary.

The report of the Committee was adopted, and the Secretary directed to transmit copies to the Secretary of the Treasury and to both branches of the next National Congress.

Dr. Deering J. Roberts offered resolutions of censure of a public newspaper in Chicago which had slandered the members of the Association.

Dr. Grissom, of North Carolina, objected to the passage of the resolutions, and moved that they be laid on the table. He considered the action recommended as unworthy the Association, and in view of its high calling it would be highly unbecoming to enter into controversy with a newspaper. (His motion prevailed.)

On motion of Dr. William Brodie, of Detroit, a proposed amendment was adopted creating a new Section on Dermatology and Syphilography. (On motion of Dr. George H. Rohé, the word "Syphilography" was substituted for "Venereal Diseases.")

A report on "Yellow Fever Legislation," Dr. J. McF. Gaston, Chairman, was, by his request, referred to the Section on State Medicine for discussion.

(To be continued.)

THE AMERICAN LARYNGOLOGICAL ASSOCIATION.

THE Ninth Annual Meeting of the Association was held in the Hall of the Academy of Medicine, New York, May 26, 27, and 28, 1887. The President, Dr. E. Fletcher Ingals, of Chicago, occupied the chair.

The meeting was opened by the delivery of the President's Address. After some preliminary matters had been discussed, he referred to

INTUBATION OF THE LARYNX.

In 1858 an attempt was made in Paris to treat stenosis by intubation. Seven cases were operated on, and of these five died and two cases recovered after subsequent tracheotomy. In 1880 O'Dwyer introduced intubation, one of the most useful operations of modern times. In the after-treatment, while the tube is in position, liquids should not be drunk by the patient.

In twelve cases of diphtheritic laryngitis he had performed intubation, in three of which recovery followed. By a coincidence, the cases of recovery were the only ones in which the author had charge of the after-treatment. One case lived eight days, and then died suddenly an hour after the tube had been removed. Another lived eight days, and then died of pneumonia. Details of the cases treated were given. As a result of his experience, he concluded that the treatment after intubation should be: 1. Prohibition of fluids except by enemata. 2. Some preparation of mercury should be given in large and frequent doses. 3. In case of development of bronchitis or pneumonia, respiratory and cardiac stimulants should be given freely but cautiously.

By correspondence and study of the literature he had collected five hundred and eighty-four cases, with one hundred and thirty-four recoveries. The percentage of recoveries will be greater when more care is exercised in the use of fluids. When medicines fail, no time should be lost in providing for the free entrance of air, either by intubation or tracheotomy. Intubation can be done more quickly, more safely, with less shock to the patient and less objection on the part of the parents. The operator should be prepared to open the trachea if loosened membrane should be forced down into the trachea. When the tube fails to relieve the dyspnœa tracheotomy should be performed, unless there is reason to believe that the latter operation will fail. When membrane is loose in the trachea, no time should be lost in the use of forceps, which rarely succeed, but tracheotomy should be resorted to. The results obtained by intubation are about as good as tracheotomy at all ages, but apparently better in young children.

The first paper read was by Charles E. Sajous, M.D., of Philadelphia, entitled

A STUDY OF SOME OF THE OBJECTIONABLE FEATURES OF INTUBATION.

Statistics favor the operation of tracheotomy at present, but the author believed intubation the better operation. The principal objections according to the degree of danger are: 1. The tendency to the obstruction of the tube by fragments of membrane. 2.

Crowding down of loose membrane during introduction of the tube. 3. Passage of food into the trachea. 4. Momentary arrest of respiration during introduction of tube. 5. Liability of the tube to be coughed out. 6. Slipping of the tube into the trachea. The tendency to obstruction was attributed to the limited diameter of the tube; the crowding down of membrane to the length of the tube; the passage of fluid to the weight of the tube; the liability to be coughed out to the limited diameter of the tube; and the slipping of the tube to the weight of the instrument and the formation of the head.

The speaker exhibited instruments on the principle of the bivalve speculum, which were intended to embody the suggestions made above. This tube obstructs the larynx very little, leaving the breathing-space almost as great as normal.

The author also exhibited an instrument intended to remove loose membrane from the larynx. The instrument consisted of forceps which could be protruded into the larynx, by an arrangement in the handle, the required distance, and the membrane grasped.

In the discussion which followed the reading of these papers Dr. Delavan suggested the use of an œsophageal tube in order to prevent ingested fluids from entering the trachea, and Dr. S. H. Chapman recommended the use of small quantities of pilocarpine to relieve thirst, and enemata or baths.

MODIFIED LARYNGECTOMY. BY J. SOLIS COHEN, M.D., OF PHILADELPHIA.

The operation is applicable to those cases in which malignant disease is not too extensive; it has the advantage over complete laryngectomy of leaving the greater portion of the thyroid cartilages undisturbed while the respiratory portion of the larynx is removed. On the cadaver the operation can be performed in two minutes. In disease limited to the interior of the respiratory tube, especially carcinomatous disease, it fulfils every indication that prompts complete laryngectomy. The advantages claimed for the operation were: 1. Rapidity, ease, and comparative safety for the patient. 2. The small size of the wound. 3. The preservation of the attachment of various important muscles and ligaments. 4. The retention of important structures in their normal relation. 5. A firm natural support is left for the application of any artificial apparatus.

The author urged that this operation should be performed in preference to complete laryngectomy except when absolutely precluded by the extent of the disease.

PRESENTATION OF INSTRUMENTS.

Dr. T. A. De Blois, of Boston, exhibited a portable apparatus for compressing air.

Dr. E. C. Morgan, of Washington, presented a universal powder-blower, which could be used in diseases of the nose, throat, vagina, or rectum.

Dr. Allen, of New York, exhibited an improved form of snare which could be used with one hand.

The following were appointed as the Nominating Committee: Drs. Beverly Robinson, of New York; W. C. Glasgow, of St. Louis; and S. H. Chapman, of New Haven.

THE PATHOLOGICAL NASAL REFLEX: AN HISTORICAL STUDY. BY JOHN N. MACKENZIE, M.D., OF BALTIMORE.

The fact is established beyond doubt that a causal relation exists between diseases of the nasal mucous membrane and other portions of the respiratory tract and many conditions of distant parts of the body. Hay-fever can be traced to the time of Galen. The fact that tickling of the nose would arrest hiccough was referred to by Plato. The irritating effect of the odor of flowers was recognized in very early times. Reference was made to the observations of various individuals in regard to reflex conditions due to nasal disease. The paper was a very interesting contribution to a subject which only recently has had its real importance acknowledged.

ANALYSIS OF CASES OF HAY-FEVER. BY JOHN O. ROE, M.D., OF ROCHESTER.

The experience of the author up to the last hay-fever season comprised forty-two cases. A study of these cases tended in the main to confirm the opinions expressed in February, 1883. Of the forty-two cases, twenty-six were males and sixteen females. The attacks came on between May 1 and August 1. In all the active symptoms subsided soon after the appearance of frost. In some cases the hay-fever dated from a severe attack of cold. In every instance there was disease of the nasal passages. The location of the sensitive areas is not constant, but they are usually most marked over the areas of greatest hypertrophy. The areas have not been confined to the posterior portion nor especially to the anterior portion of the turbinated bones. In the majority of cases the septum was as sensitive as the turbinated bones. Thirty-one patients suffered with asthma. But twelve patients had a distinctly nervous temperament, while nine were distinctly phlegmatic.

The plan of treatment adopted is to restore the nasal passages as nearly as possible to their normal condition, and to destroy the sensitive areas by cauterization. Deep cauterization has been most effective, while superficial cauterization had no marked effect. The condition of the larynx, pharynx, and bronchi must not be overlooked. Not infrequently enlarged tonsils will keep up irritation in the turbinated bones. A neglect to cure a bronchitis may account for the return of the disease.

Thirty-five of these cases have practically been cured. Seventeen have remained exempt for periods varying from one to nine years. Four were not relieved owing to imperfect treatment; and five have been lost sight of. The following conclusions were presented:

1. All cases of hay-fever have their initial lesion in a diseased condition of the tissues of the nasal fossa.

2. All diseases of these tissues induce in the ganglionic centres connected with them an abnormal activity, which is reflected to other organs.

3. The sensitive areas in the nose are not found in any particular portion of the cavity. Nor are there any zones which when irritated produce always the same manifestations.

4. The direction in which the irritation is reflected is always in the line of least resistance. Irritation in the same region may be reflected in one direction at one time, and in another direction at another time.

5. The disease in the nose may produce disease in other portions of the respiratory tract, which may become independent centres of irritation.

6. The affection recognized as hay-fever is due to local irritations brought in contact with the sensitive areas in the nose.

7. The affection is not *per se* neurotic; nor is the so-called neurotic condition of the person necessary to render a person susceptible to local irritation applied to the air-passages. It is not necessarily associated with the nervous temperament.

8. The neurotic condition which is often regarded as the cause of the hay-fever is often the result of the local irritation.

9. By careful and thorough treatment of the disease of the nasal tissue combined with that of other portions of the respiratory passages below, which have become secondary sources of irritation, we need not fail to cure hay-fever.

In the discussion, Dr. C. E. Sajous, of Philadelphia, advocated deep cauterization. Drs. Mackenzie, Glasgow, Hooper, and Cohen regarded hay-fever as a general neurosis. Dr. Knight mentioned a case which had been arrested in its course by the fracture of a leg, and another after a consultation with a disciple of mind-cure.

ON THE TREATMENT OF ATROPHIC RHINITIS BY APPLICATIONS OF THE GALVANIC CURRENT. BY D. BRYSON DELAVAN, M.D., OF NEW YORK.

Some years ago, Dr. E. L. Shurly, of Detroit, recommended the use of the galvanic current in the treatment of dry catarrh of the pharynx, and related cases in which benefit had followed its use. He also advocated the same treatment in atrophic rhinitis. There is no disease which is more discouraging to the physician and patient than this of atrophic rhinitis. The author had tried this method of treatment in certain cases. The positive pole of a constant-current battery was applied to the nape of the neck, while the negative pole was applied directly to the mucous membrane by an electrode consisting of a copper wire around which absorbent cotton is wrapped. The strength of current employed varied from four to seven milliampères. In more recent cases of the affection the effect is marked, but even in the older cases the method is not without benefit. The author had found this measure useful in these cases, and reported illustrations. The objection to the method is the amount of time it requires.

Dr. De Blois said that he had obtained good results from the treatment by galvanism. Dr. Knight recommended temporary plugging of the nostrils. Weak (five- to ten-grain-) solutions applied every other day were approved by Dr. Roe, and chromic acid by Dr. Sajous.

The next paper was on

MYALGIA OF THE PHARYNX AND LARYNX. BY DR. S. H. CHAPMAN, OF NEW HAVEN,

in which the speaker called attention to certain peculiar conditions of the muscles of the upper air-passages which occur oftentimes in malarial disorders, and which, on account of their severity, may be brought to the notice of the specialist. The muscles most likely to be affected are the pectoral, the muscles of deglutition, and those of the larynx.

SENSORY AFFECTIONS OF THE THROAT. BY DR. F. I. KNIGHT, OF BOSTON.

The author especially referred to hyperæsthesia and paræsthesia. In hyperæsthesia the general condition of the patient is as a rule not sufficiently considered. The worst cases are alcoholic subjects and those with digestive disorders. These will often yield to withdrawal of the alcohol and regulation of the diet. Astringents are frequently of service. In the cases of paræsthesia which he had seen there had been a feeling of fulness, pressure, burning, globus hystericus, or the sensation of a foreign body in the throat. In these cases there is impairment of the general nervous system. The exciting cause may be some disease of the throat. Fatigue usually exaggerates these sensations. He had never met with paræsthesia of the larynx as the earliest symptom of phthisis, as had been claimed by some observers. The prognosis in most cases of paræsthesia is good if a careful treatment be carried out. The treatment of the neurosis of sensation must be aimed to cure the constitutional vice.

In the discussion cases were mentioned in which neuralgic pains were associated with syphilis, in others it seemed to be rheumatic or gouty.

(To be continued.)

AMERICAN SURGICAL ASSOCIATION.

(Continued from page 614.)

Third Day, Morning Session.

IN executive session the following officers were chosen for the ensuing year:

President.—D. Hayes Agnew, M.D., of Philadelphia.

Vice-Presidents.—N. Senn, M.D., of Milwaukee, and F. S. Dennis, M.D., of New York.

Secretary.—Jacob R. Weist, M.D., of Richmond, Indiana.

Treasurer.—Phineas S. Conner, M.D., of Cincinnati, Ohio.

Recorder.—J. Ewing Mears, M.D., of Philadelphia.

Council.—J. S. Billings, M.D., L. McLane Tiffany, M.D., Moses Gunn, M.D., and R. A. Kinloch, M.D.

Chairman of Committee of Arrangements.—John S. Billings, M.D., of Washington.

The following were elected to membership: Charles B. Porter, M.D., of Boston; William M. Masten, M.D., of Mobile; and Morris H. Richardson, M.D., of Boston.

The next meeting is to be held at the call of the President.

SURGICAL DISEASES OF THE WHITE AND COLORED RACES COMPARED. BY L. McLANE TIFFANY, M.D., OF BALTIMORE.

The paper was based on the record of four thousand nine hundred and thirty cases studied during a period of thirty-four months in a general hospital. The percentages of the affections were given in detail. The paper was simply intended as a preliminary communication, and, as a result of a study of the figures obtained, the following suggestions were made:

1. Surgical affections follow different courses in the white and colored races under identical hygienic surroundings.

2. Surgical injuries and operations are better borne by negroes than by whites.

3. Surgical diseases involving the lymphatic system, especially tubercular, are more fatal and more rapidly fatal in negroes than in whites.

4. Congenital deformities are rarer in negroes than in whites.

5. The surgical differences observed in whites and negroes are due to racial peculiarities.

DISCUSSION.

Dr. Christopher Johnston, of Baltimore, in opening the discussion, said that his experiences indicated that there are individual as well as racial peculiarities. These are most striking in proportion to the pureness of blood. The negro is a good subject for surgical operation. He had never seen carbuncle in the negro; nor could he recall a cleft palate or hare-lip in the darker individuals. Epithelioma is infrequent. Fibromas are quite frequent. He wished to emphasize the proneness to the development of keloid in the negro, and had found that in the negro the skin and white fibrous tissues are more frequently the seat of certain diseases than the same tissues in the white.

Dr. T. H. Richardson, of New Orleans, presented a detailed report of the statistics of the Charity Hospital bearing upon this point. He had found congenital deformities rarely in the negro.

Dr. E. H. Gregory, of St. Louis, said that he had seen keloid much more frequently in negroes than in whites, and he had never seen multiple keloid in the white race. The ability of the negro to stand operation may be due to his indifference and his inability to comprehend the magnitude of the operation. The results obtained at the City Hospital of St. Louis show that the negroes bear operations about as well as whites. It seems to be the generally-accepted idea that negroes are more subject to tubercular affections.

Dr. W. T. Briggs, of Nashville, Tennessee, said that his experience confirmed the suggestions of Dr. Tiffany. Negroes are very prone to suppuration. It is extremely difficult to prevent suppuration, even under strict antiseptic precautions. Negroes bear operations better than whites, but they do not get well so rapidly. While malformations are less frequent, still they do occur. The rarity of hydrocele in the hospital-records may be explained by the fact that negroes do not usually seek advice until the tumor has become so large as to give rise to much inconvenience. Fibroids and fibro-cystoma are very common in the negro. Ovarian tumor is rare, although he had had one case in which the tumor weighed one hundred pounds.

Dr. D. W. Yandell, Louisville, Kentucky, agreed with Dr. Briggs. He had seen many cases of keloid in the negro, but not a case in the white subject. He had seen but two cases of hydrocele in the negro, and never saw hare-lip, and but two ovarian tumors in the negroes. He never saw epithelioma of the face in a negro. Epilepsy is exceedingly rare in the negro. He had never seen a case of internal hemorrhoids in the negro. Tetanus is exceedingly common, especially in the black race. Stricture of urethra is exceedingly common among negroes.

Dr. R. A. Kinloch, Charleston, South Carolina: In considering this subject we make a mistake in classing all negroes together. In the pure negro suppuration is less likely to occur than in the white race. As a rule, the negro is not strumous, but mulattoes are. The pure negro bears operation well and recovers promptly.

Dr. A. Vanderveer, of Albany, during the past twenty years had seen a good many negro patients among the United States prisoners sent to the Albany penitentiary. The

vast majority of these die of tuberculosis of some form. Many of them have soft chancre with suppurative buboes. Where there is true Hunterian chancre, there has been the characteristic bullet bubo seen in the white race. There are a greater number of perineal abscesses and sinuses than in the white. If operation is done, there is less probability of urethral fever.

AN EXPERIMENTAL STUDY OF THE EFFECTS OF PUNCTURE OF THE HEART IN CASES OF CHLOROFORM-NARCOSIS. BY B. A. WATSON, M.D., OF JERSEY CITY, NEW JERSEY.

The investigation of this subject was suggested to him by the following occurrence. February 20, 1887, he had with chloroform killed a dog. The abdominal and thoracic cavities were opened about four minutes after the heart had ceased to beat. The assistant seized the heart with his thumb and forefinger, and the pulsations at once began, the contractions became full and regular, and continued three minutes. They were again stimulated by a second touch, action continuing two minutes. They were started a third time, and continued to beat one-half minute. This observation suggested the possibility of arousing the heart into action, even after entire cessation of its movements, by the introduction of a needle into the organ.

[The results of sixty experiments on dogs were given in detail. The experiment consisted briefly in producing death by chloroform-inhalation, and then, within from one to three or four minutes, an aspirating-needle was introduced into the heart through the chest-walls, the attempt being to reach the right ventricle. In the first fifty cases the chloroform was administered rapidly, and air was excluded as far as was possible. In the last ten the chloroform was administered slowly and with a large proportion of air. The first forty animals had already suffered some severe traumatic injury, while the last twenty were perfectly healthy animals. The punctures made in these sixty experiments were as follows: right ventricle, thirty-eight; left ventricle, six; right auricle, six; superior vena cava, three; inferior vena cava, two; apex of the heart, two; and not stated, one. The resuscitations were as follows: after puncture of the right ventricle, nine; right auricle, one. The first forty experiments gave only four recoveries, while the last twenty gave six. In only one of the sixty cases did the heart fail to respond to puncture, and in this instance the use of the needle was postponed for four minutes after the cessation of the heart's action, and one minute after breathing had stopped.]

Should the puncture be carried into one of the cavities of the heart in order that blood may be abstracted? In chloroform-narcosis the heart is found in diastole and the veins in the lungs are greatly distended with blood. It may, therefore, theoretically be assumed that blood may be advantageously drawn from the right side of the heart. The author was assured that this procedure was practical and advantageous.

The only deaths during these experiments which could be attributed directly to the puncture were those in which the needle penetrated the vena cava. In these cases there was profuse hemorrhage into the thoracic cavity. Punctures made into the auricle are sometimes followed by a flow of blood into the pericardium. Punctures into the ventricle are not attended with any hemorrhage from the interior of the organ, but there may be a few drops of blood from a wounded cardiac vein.

The following conclusions were reached:

First. Puncture of the heart, especially of the right ventricle, stimulates muscular contractions, and may be advantageously applied in the treatment of chloroform-narcosis.

Secondly. The best results are obtained when abstraction of blood from the cavity of the ventricle is combined with the stimulating effects produced by the entrance of the aspirator-needle.

Thirdly. The puncture of the right ventricle is a safer and more efficient operative procedure than the puncture of the right ventricle.

DISCUSSION.

Dr. N. P. Dandridge, of Cincinnati: We should be careful how we apply the deductions from these experiments to the human being. The conditions under which the experiments were made are different from those under which accidents usually occur in human beings. Accidents usually occur after only a small quantity has been taken, and often early in its administration. The effect is probably due to a reflex effect upon the inhibitory action of the heart. In the experiments reported, puncture was resorted to within one or two minutes after the cessation of the heart's action. In the accidents with chloroform it is not uncommon to have recovery after apparent cessation of the heart's action for a comparatively longer period. A large number of experiments are required to test the relative value of this procedure as compared with artificial respiration. The use of nitrite of amyl, and particularly with the subcutaneous injection of atropine, can always be done quickly, and has a stimulating effect upon the cardiac and respiratory centres.

Dr. John B. Roberts, of Philadelphia: While he has shown the comparative innocuousness of puncture of the heart with a small needle, the speaker has also shown the danger of using chloroform as an anæsthetic in any cases, possibly cases of parturition excepted. It is doubtful whether he could have killed the same number of dogs with

ether. His experiments have shown that it is more dangerous to puncture the auricle than the ventricle, which would naturally be suggested by the fact that the auricle has a much thinner wall. Dr. Westbrook, who performed cardiocentesis for conditions other than chloroform-narcosis, suggested puncture of the right auricle to the right of the sternum. The speaker had suggested, in 1883, that it would be better to puncture the right ventricle to the left of the sternum.

Dr. L. McLane Tiffany, of Baltimore: There are two points in which these experiments are open to criticism. It is well known that on dogs chloroform acts in a very uncertain manner. It is not safe to make deductions from the dog to the human being under these circumstances. In the second place, it is not well to make experiments in the laboratory and then advise others to try them on the human subject. The experimenter should test the experiments on the human subject before he recommends the procedure to others.

Dr. R. A. Kinloch, Charleston: In a recent case of chloroform-narcosis in my practice heart-puncture was tried, but without the slightest benefit.

Dr. T. J. Dunott, of Harrisburg, knows of one case in which the heart was twice punctured with an aspirator-needle and blood drawn from the cavity of the heart. It was a case of dilatation of the heart, with general dropsy, etc. The operation was performed by a homœopathic practitioner under the idea that he was dealing with a case of dropsy of the pericardium. A large quantity of blood was removed, and for a time there was improvement. The symptoms again returned, and the operation was repeated, but with a fatal result.

Dr. B. A. Watson said, in conclusion, that reference to the details of these experiments showed that in some the heart was excited to action fully three minutes after it had ceased. There are two reasons for selecting the right ventricle in place of the right auricle. In the first place, the risk of hemorrhage is less; in the second place, there is much more muscular substance in the wall of the ventricle than in the auricle.

With reference to the action of chloroform on the dog, I am well aware of the uncertainty of its action; but this is all against the dog. Where I have attempted to continue the anæsthetic action of chloroform on dogs for two hours, I lost one-half of the animals.

REPORT OF COMMITTEE ON THE PRESIDENT'S ADDRESS.

The Committee to which was referred the suggestions contained in the President's Address reported that, in view of the satisfactory manner in which the work of the present meeting had been prepared, it saw no reason for a change, and did not recommend the appointment of a Business Committee. It recommended the adoption of the second suggestion, with reference to the length of papers. With reference to the abrogation of Article IX. of the Constitution, the Committee was in accord with the President; but, as this article had been introduced at the express desire of the first President of the Association, it was recommended that it be allowed to remain. The Committee recommended the adoption of the suggestion that applications for membership should lie over for one year.

Afternoon Session.

HYPERTROPHY OF THE TONGUE, OTHERWISE KNOWN AS LINGUA VITULI, LINGUA PROPENDULÆ, AND MACROGLOSSIA. BY T. J. DUNOTT, M.D., OF HARRISBURG.

This affection of the tongue, although rare, is mentioned by nearly all surgeons of large experience. The case described by the speaker was that of a girl, 12 years of age, admitted to the Harrisburg Hospital January 6, 1886. The tongue protruded from the mouth a distance of three and five-eighths inches. The lips were greatly distended, and the angles of the mouth not far removed from the external opening of the auditory canal. The greatest width of the tongue was four and three-fourths inches, and the greatest circumference nine and three-fourths inches. The prolapse of the tongue was only of two months' duration, and had begun without apparent cause. The measurements taken one week after admission showed a decided increase in the size of the tongue. The tongue was removed February 19. After providing against hemorrhage, the organ was removed with scalpel and scissors, the section being so made as to secure a conical stump. All the dense fibrous mass was taken away, the weight of the removed portion being over ten ounces. By January 31 the stump was entirely healed. There was no difficulty in keeping the mouth closed. When heard from, March 23, she could eat and drink without difficulty, and was gaining flesh rapidly. The paper was concluded with an account of the various operations which had been practised for the removal of the tongue.

DISCUSSION.

Dr. L. McLane Tiffany, of Baltimore, said that the history of the case just given would well apply to a case which he had recently seen. A negro girl, 5 years of age, had suffered with hypertrophy of the tongue, dating from birth. Ever since the first few months of life the child had been unable to cover the tongue with its lips. The redundant portion of the tongue was removed with the Paquelin cautery. Within a week the patient was eating potatoes and meat, and left the hospital ten days after operation. At this time there was a healthy granulating surface.

CASES OF VAGINAL HYSTERECTOMY. BY J. FORD THOMPSON, M.D., OF WASHINGTON.

Case I.—Mrs. A. E., aged 45 years, white, was seen in April, 1885, suffering with malignant disease of the uterus. There was great destruction of the cervix, the ulceration extending above the internal os. On consultation, it was decided to avoid hysterectomy if possible, but to limit the operation to amputation of the cervix, with scraping, etc. During the operation the peritoneal cavity was opened. It was then decided to extirpate the uterus. The womb was separated from the bladder in front. A ligature was then placed around each broad ligament and tied. The uterus was then split in two. Each half was then brought down, the broad ligaments tied above the temporary ligatures, and the uterus removed. After thorough cleansing, the vagina was lightly packed with iodoform-gauze. At the end of the operation the patient was very weak, and, notwithstanding all efforts, died in the course of twenty-four hours.

Case II.—Mrs. H., white, aged 55 years, came under observation with cancer of the cervix in January, 1887. The posterior lip of the cervix was almost entirely destroyed, and the disease had encroached upon the posterior cul-de-sac. The cervical canal was involved at least as high as the internal os. The operation was performed February 28, 1887, antiseptic precautions being adopted throughout. The dissection was begun at the posterior part and carried around the cervix. A silk ligature was passed with a long curved needle through the lateral vaginal vault of either side and tied. The enclosed portion was then cut from the uterus. These ligatures presumably enclosed the uterine arteries and the lower part of the broad ligament. The uterus was then separated from the bladder in front, and a loop of silk was attached to the peritoneum. The posterior cul-de-sac was treated in the same way. The uterus was then tilted through the opening, and the broad ligaments transfixed and tied. There was no loss of blood. The peritoneal flaps were then brought together with two catgut sutures and a drainage-tube was introduced into each angle of the wound. The vagina was packed with iodoform-gauze. The patient recovered without any unpleasant symptoms.

Reference was then made to the history of the operation, and the various methods of performing it were described.

DISCUSSION.

Dr. T. R. Varick, of Jersey City: Whether such operations as this are likely to mitigate suffering or to prolong life beyond the average duration of the disease if left to take its course without interference, is a question yet to be determined. It would seem that any operation or method of treatment whose record does not show a prolongation of life beyond the utmost limit of the duration of the disease if left to itself is useless and should be avoided.

Dr. T. F. Prewitt thoroughly agreed with the author that extirpation of the uterus is a justifiable operation, and he did not know but that he was prepared to go still further and say that, on the earliest appearance of epithelioma of the cervix, the whole organ should be extirpated. He believed that ultimately this will be the course generally adopted.

Dr. E. H. Gregory, of St. Louis: It is one of the rules of old surgery to save every part possible, and I should no more think of removing the entire uterus for epithelioma of the cervix than I should think of removing the whole lip for limited epithelioma of that part. The surgery of the lips and the surgery of the jaws is applicable to the uterus.

Dr. R. A. Kinloch, of Charleston: Another of the rules of old surgery was that in malignant diseases we should cut far and wide. The older surgeons, as well as the modern, recognized the fact that malignant disease often spreads too rapidly for us. Here we have an organ suspended in the pelvis and easily isolated. Now, if statistics show that by cutting far and wide, without jeopardizing life too much, we can cut short the disease, we are carrying out the rules of old surgery when we do so.

The next paper was the report of a case of

ANEURISM OF THE LEFT SUBCLAVIAN ARTERY, FOR THE CURE OF WHICH THREE METHODS OF TREATMENT WERE EMPLOYED. BY T. G. RICHARDSON, M.D., OF NEW ORLEANS.

The patient, a healthy, muscular Irish laborer, came under observation October 19, 1885. Aneurism of the left subclavian artery was recognized. The patient had suffered with syphilis, and constitutional measures were first tried. Iodide of potassium in fifteen- or twenty-grain doses was given three times a day. At the end of a week, no perceptible effect being observed, it was discontinued. Direct pressure was next tried; an elastic band with a compress over the vessel was secured to a belt around the waist. This was continued a month, and, although it slightly retarded the growth of the swelling, it had had no decided result. The third method, the introduction of surgical pins, was next resorted to. Nineteen of these—measuring an inch and a half in length—were passed through the anterior wall of the tumor at different places. The aneurism was still growing rapidly, and all the pins that could be reached were withdrawn. Some of them had disappeared on account of the swelling which had taken place. An attempt was then made to ligate the axillary artery; but in spite of the utmost care the lower portion of the aneurism was ruptured in the progress of the operation. The wound was at once packed

with lint dipped in Monsel's solution. The hemorrhage having been stopped, half a drachm of a five-per-cent. solution of perchloride of iron was injected into the centre of the tumor. At the end of twenty-four hours, no coagulation having taken place, a second injection of twice the strength was employed. The next morning there was an exhausting hemorrhage, ending fatally in a few hours.

A CASE OF FEMORAL ANEURISM CURED BY ELEVATION AND FLEXION OF THE LIMB

was reported also by Dr. T. G. Richardson, of New Orleans.

The patient, an Italian, aged 55 years, was admitted to the hospital December 11, 1886, with a large aneurism of the femoral artery four inches below the femoral arch. While the case was being studied the limb was flexed at a right angle at the hip and knee and suspended on a Smith's anterior splint. The next day the pulsation was greatly reduced and the patient was quite comfortable. The treatment was continued, and at the end of the third day the tumor was solid. The limb was kept in this position for ten days or two weeks. The patient was discharged cured one week later. The speaker called attention to the fact that there was no direct pressure upon the tumor, and that the result was due entirely to flexion and suspension of the limb.

WOUNDS: THEIR ASEPTIC AND ANTISEPTIC TREATMENT,

was the subject of a paper read by David Prince, M.D., of Jacksonville, Illinois.

After referring in general terms to the methods in use for the prevention of contamination of wounds, the speaker described an operating-room which he had devised, the object of which was to prevent the entrance of infecting principles. All the air entering this room is filtered through successive layers of cotton. The air is heated by means of gas-burners, and to prevent drying of the wound steam is permitted to enter with the air.

The next paper was entitled "Splenotomy." It was presented by James McCann, M.D., of Pittsburg, and communicated the notes of a case in which removal of the spleen had been practised with recovery of the patient.

A paper entitled "The Study of the Methods of Operation practised and of the Results obtained in the Treatment of Cleft of the Hard and Soft Palates, illustrated by the Record of Fifty Cases," by J. Ewing Mears, M.D., of Philadelphia, was read by title.

A vote of thanks was then extended to the Surgeon-General of the United States for the use of the room, to the Cosmos Club for courtesies extended, and to the officers of the Association for the efficient manner in which the proceedings had been conducted.

The Association then adjourned.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

A STATED meeting of the Society was held April 27, 1887, H. AUGUSTUS WILSON, M.D., in the chair.

Dr. H. M. FUSSELL read a paper on

THE DIAGNOSTIC VALUE OF TUBERCLE-BACILLI IN SPUTA.

In looking over the literature relating to this subject, I have found but few writers among Americans, while the foreign journals of 1883 and 1884 contain numerous articles pertaining to it. At that time the subject was new, and it might be objected that the writers in those years were carried away by the glamour of the subject. That objection at least cannot be made to an article written now, five years after Koch's discovery, and more than four years since its application to the examination of sputa.

Without exception, the writers spoken of above agree that as a diagnostic sign of phthisis tubercle-bacilli found in sputa are of the greatest practical importance.

Heron (*Lancet*, February 3, 1883) examined sputa from sixty-two cases, and found bacilli in all but three. He comes to the conclusion that "the presence of the bacillus of tubercle in sputum is sufficient to fix the identity of certain cases of disease."

West (*Lancet*, February 25, 1883) thinks bacilli in sputa may be of diagnostic value in some doubtful cases, but generally they are in confirmation of what is made plain by physical signs.

Williams (*Lancet*, February 24, 1883) examined one hundred and thirty specimens of sputum; twenty-one cases were of various diseases other than phthisis,—asthma, bronchitis, etc.; one hundred and nine cases of various forms of phthisis; one hundred and six of the one hundred and nine cases contained bacilli.

Sée is a firm believer in the diagnostic value of tubercle-bacilli in sputa.

Dreschfeld examined forty-six cases in which physical signs were marked, and three doubtful cases,—two with no physical signs, one with an apex-catarrh only. He concludes that tubercle-bacilli in sputa are of the greatest diagnostic value, but of no prognostic value.

Licht found bacilli in sputa of all of twelve cases of phthisis.

Heron (*British Med. Journal*, April 28, 1883) found tubercle-bacilli in sputa of one hundred and sixteen cases. In the majority of cases there could have been no reasonable doubt because of the physical signs, but in a few cases where bacilli were found there were but few physical signs.

Marchiafava and Celli are quoted in the *London Med. Record* of January 15, 1886, as having found Koch's bacillus in sputa of fif-

teen cases of phthisis, in one case of slight catarrh of apex, and in one case of hæmoptysis without signs. They failed to find it in six cases of chronic bronchitis and one case of syphilitic inflammation.

Negri and Pinolini (*London Med. Record*, January 15, 1886) diagnosticated phthisis by the examination of sputum, and confirmed the diagnosis by subsequent physical examination.

Voblyi (*British Med. Journal*, 1883) found tubercle-bacilli in sputa of all of thirty-five cases of phthisis. No tubercle-bacilli were found in eighteen cases of various other lung-diseases. In some of the cases of phthisis the physical signs were at first meagre, but became more evident after a time.

Dreschfeld (*British Med. Journal*, February 17, 1883) examined sputa of three cases of hæmoptysis without evident physical signs of phthisis. Tubercle-bacilli were found in all the cases.

Prudden (*New York Med. Record*, April 14, 1883) examined fifty-eight specimens of sputa. Tubercle-bacilli were present in forty-six cases.

Austin Flint, Sr., says the results of the examinations of various specimens of sputa for tubercle-bacilli satisfy him that bacilli in sputum may be relied upon as proof of the existence of tuberculous disease.

If repeated examinations made with sufficient care show the presence of tubercle-bacilli, the diagnosis of phthisis is positive; and, on the other hand, if on repeated and careful examinations tubercle-bacilli be *not* found, phthisis may with much probability be excluded.

I venture to predict that the time will soon come when, in order to corroborate the diagnosis, and as the hinge on which the diagnosis will turn in certain cases, microscopical examinations of the sputa will be considered as much a matter of course as examinations of urine for evidence of renal disease.

My personal observations, as set forth below, confirm the above opinions and enable me to reaffirm that the presence of tubercle-bacilli in sputa is diagnostic proof of the presence of tuberculous phthisis. In the examination of my cases I used a modification of Gibbe's method suggested by Professor William Osler.

The sputum was spread as thinly as possible on a thin cover-glass, allowed to dry in the air, and passed quickly two or three times through the flame of a spirit-lamp. The cover-glass was then immersed in solution of magenta, manufactured by Beck & Co., and allowed to remain fifteen minutes, after first slightly heating. It was then decolorized in alcohol, acidified with hydrochloric acid (four or five drops to a watchglassful of alcohol), and examined under a moderately high power.

In this manner the whole proceeding can be done in less than half an hour. If bacilli were not found by the rapid method, however, the glasses were allowed to remain in magenta over-night, and then examined as before. The power used at first was Hartnack No. 9 immersion, afterwards 7 objective, 4 eyepiece. Lower power may be used, however, by one perfectly familiar with the bacillus. I have used a Zentmeyer one-fifth with A eyepiece.

The sputa from one hundred cases of lung-disease were examined.

For convenience we may divide these cases into two classes, I. and II.

Class I. contains eighty-four cases. The sputa of all these cases contained tubercle-bacilli.

Class II. contains sixteen cases. Tubercle-bacilli were *not* found in the sputa from any of these cases.

Each of the above classes may be subdivided—

Class I.

Subdivision A contains seventy-nine cases in which there were evident physical signs of phthisis.

Subdivision B contains five cases in which there were few or no physical signs of phthisis. The diagnosis was made by the presence of bacilli in the sputa.

Class II.

Subdivision C contains eight cases in which phthisis was *not* suspected from the physical signs, and no bacilli were found.

Subdivision D contains eight cases in which the physical signs led to a suspicion of phthisis, but the absence of tubercle-bacilli and the subsequent history proved it to be absent.

It is in such cases as those of Subdivisions B and D that the presence or absence of tubercle-bacilli in the sputa is of such practical value, and it will be well to take these cases in detail, referring the more curious to the summary attached for an account of each case.

We will first give our attention to the five cases under Subdivision B, or those in which the physical signs did not warrant a diagnosis of phthisis and in which tubercle-bacilli were found, the subsequent history proving the correctness of a diagnosis of phthisis made after examination of the sputa.

Case XVII.—Thomas R., aged 41, of good family history. Cough, hectic, and loss of flesh for eight weeks. Physical signs at first examination were entirely inadequate to base a diagnosis of phthisis upon. Examination of sputa at second visit showed the presence of myriads of tubercle-bacilli. Afterwards consolidation at right apex developed. The case ran a rapid course, and death took place within the year.

Case XXV.—May C., aged 21. Both parents dead of phthisis; cough, hectic, loss

of flesh. Examination of throat showed the presence of a polypoid growth. Physical signs were inadequate to base a diagnosis upon, though there were some signs of congestion at right apex. Examination of sputa showed numerous tubercle-bacilli. Rapid consolidation took place; death in eight months at the Episcopal Hospital.

Case XVIII.—Annie W., aged 35. Husband died of phthisis six months before patient came under observation. She was suffering from extreme dyspnœa and cough. Œdema of feet, having had an attack of general œdema some weeks previously. Examination of chest showed a mitral systolic murmur. The heart was beating very rapidly. The symptoms were attributed to the heart-lesion. No signs of consolidation could be found after careful examination. On examination of sputa, they were found loaded with tubercle-bacilli. She was admitted to the University Hospital; gradually failed; her chills and fever becoming more marked. Repeated examination of sputa always showed bacilli; finally signs of consolidation at right apex developed.

Case XX.—Mrs. R. Cough, slight expectoration, meagre physical signs. A few tubercle-bacilli found. Eight months have passed since the first examination. In the mean time the woman has become pregnant, and her health has improved, though the cough still remains. January 17, 1887, child born; cough returned, sputa re-examined, bacilli found. More evident signs of consolidation at apex.

Case C.—Mrs. H. Good family history. There was an attack of pneumonia three years ago. Since then health has been gradually failing. Now there are cough, hectic, loss of flesh. Slight consolidation at left apex. This woman was taken for consultation to one of the first diagnosticians of the city. The consolidation was recognized, but the case pronounced one of a probable catarrhal character. The sputa from this case were afterwards given to me, and myriads of tubercle-bacilli found. April 21, the case has grown rapidly worse, and death is expected daily.

As was stated in the history of these cases, the physical signs did not warrant a diagnosis of phthisis. The examination of the sputa was made because the cases were doubtful and interesting, for the sake of making the diagnosis. Though no better in these instances for the patient, it was a comfort to the physician as a diagnostician when the histories proved the correctness of his diagnosis of phthisis.

No less interesting and instructive than the above are the eight cases coming under Subdivision D, where the history and physical signs gave a strong suspicion of phthisis. No bacilli were found in any case, and complete recovery took place in five of the cases, two became much better, and one died of the results of an acute and, as I claim, croupous pneumonia.

Case XIV.—John C., aged 66. For four months there had been cough, hectic, sweats, and loss of flesh. There were signs of consolidation at right base. Under treatment the lung cleared up and the man made a good recovery. Repeated examination failed to show bacilli.

Case I.—William R. Family history of phthisis. Cough, some loss of flesh, hectic. Consolidation at left base. No bacilli were found. Under treatment lung cleared up, and one year afterwards he returned to the dispensary entirely well of lung-trouble.

Case III.—Walter L., aged 20. Good family history. Cough for one month. A sudden, rather profuse, hemorrhage. There were slight fever and signs of congestion at left apex. No bacilli were ever found. One year afterwards no return of trouble, and seems perfectly well.

Case VIII.—Alma N., aged 25. Uncle died of phthisis. Cough with slight loss of flesh for three months. The left apex dull, full of mucous râles, prolonged expiration. No bacilli found after repeated examinations. The lung cleared up, cough stopped, and one year after patient seemed perfectly well.

Case VI.—K. H., aged 35, with a good family history, had an attack of pneumonia eighteen months before she came under observation (declares she was perfectly well before). Since then has had cough, hemorrhage, hectic, loss of strength, but not of flesh, copious expectoration. On examination a large cavity was found at right apex. Repeated careful examinations failed to show tubercle-bacilli. The patient remained under observation for six months, and was in about the same condition as at first. This must have been either a cavity due to breaking down of lung following pneumonia, or, as Professor Flint suggests, one in which the tubercular process had become cured or was dormant.

Case VII.—A girl, aged 7. Perfectly well until ten weeks before she came under observation. At that time she had an attack of what was apparently acute pneumonia of the right apex. She did not rally. The lung broke down, and at the time she was seen there was a cavity at right apex. The patient died from exhaustion four weeks after. No bacilli were ever found in sputum.

Case II.—Man, aged 29, with a family history of phthisis. Had an attack of hæmoptysis in the fall of 1884; during that winter severe cough and loss of flesh. There were physical signs of consolidation at left apex. No bacilli were found after careful and repeated examinations. The man gradually improved, and now, April, 1887, is apparently well, though there is still some dulness at left

apex; he is able to work, and does not complain.

Case XV.—Sallie K., aged 29. Good family history. About one month before she came under observation began to have cough, fever, pain, rapid loss of flesh. She was found in bed, emaciated, slight fever, 101° F., extreme dyspnœa, diarrhœa, and presented the picture of one in advanced phthisis; indeed, such had the case been pronounced. I found but few physical signs. There was consolidation at left base, however. Repeated examination failed to show bacilli. Under vigorous treatment the patient revived, and now is perfectly well. Evidently a case of neglected pneumonia.

Of the seventy-nine cases belonging to Subdivision A there could have been no reasonable doubt of the existence of phthisis, basing the opinion on the physical signs present. Tubercle-bacilli were found in each case.

Subdivision C contained eight cases,—two of chronic pleurisy and six of chronic or subacute bronchitis. The sputa from each case were repeatedly examined, and no bacilli were ever found.

As most of the cases reported were taken from my service at the University Medical Dispensary, and as dispensary cases as a rule are not long under observation, it is impossible to draw any positive conclusions from these cases as to the relation between the bacillus and prognosis in phthisis, but in Cases XVII., XIX., and LXXVII., which ran a fatal course within a year, and in Cases XXXI., XXXIII., XXXVII., XXXIX., XLVIII., LVII., LXXVI., and XCVI., which were examined near to the time of death, tubercle-bacilli were unusually abundant. Especially was this the fact in Case LVII., which was examined about ten days before death.

In conclusion, I wish to acknowledge my indebtedness to Professor Osler, to whom I owe my knowledge of the *technique* of the work, and to Drs. John H. Musser, of Philadelphia, and R. R. Bunting, of Roxborough, for opportunity given to examine sputa of their cases.

DISCUSSION.

Dr. W. Osler: I think that the importance of the tubercle-bacillus in the sputum as a means of diagnosis is not sufficiently recognized by the profession. The technical skill required is not very great, and the time required with the rapid methods of staining is not more than fifteen to thirty minutes. I have succeeded in demonstrating the bacillus within five minutes from the time that the sputum was put upon the slide. This examination is particularly serviceable in just those cases where the evidences of disease are very slight. Only within the past few weeks there was in the University Hospital a man without any pulmonary signs who had been failing in health and had slight fever. The condition was attributed to some obscure abdominal disease. Finally a suspicion arose that there might be some trouble with the lung, and the sputa were examined and the bacilli found. The signs of phthisis have since developed. The power required for these examinations need not be, as Dr. Fussell says, very high.

Dr. Frank Woodbury reported a case of "Laparotomy for Perityphlitic Abscess, with Removal of the Vermiform Appendix." (See page 593).

AMERICAN ORTHOPÆDIC ASSOCIATION.

THE first meeting of this new special organization was held at the New York Academy of Medicine, New York, June 15 and 16, 1887.

After assembling, the Association organized by electing Dr. Virgil P. Gibney, of New York, temporary Chairman, and Dr. Louis Hall Sayre, of New York, temporary Secretary. The proceedings were interesting and varied.

The following papers were read and discussed:

Dr. Packard, of Hartford, read the history of a case of enlargement and elongation of the lower extremity.

Dr. Morton, of Philadelphia, presented an instrument for the forcible correction of club-foot.

Dr. Sayre, of New York, exhibited a case of talipes equino-varus treated by division of the tendo Achillis.

Dr. Gibney, of New York, exhibited two cases of chronic osteitis of the shoulder-joint.

Dr. Taylor, of New York, read notes on a case of Pott's disease.

Dr. Judson, of New York, exhibited a new form of ischiatic crutch.

Dr. A. Sydney Roberts, of Philadelphia, made some remarks on spurious valgus (flat-foot), and showed a new form of plantar spring for treatment.

Dr. Bradford, of Boston, presented specimens and the history of a case of hip-joint disease.

Dr. Sayre, of New York, presented specimens from a case of excision of the hip.

Dr. Gibney, for Dr. Morgan Vance, of Louisville, presented a specimen of a rudimentary tail that had been removed from a negro.

Dr. Ridlon, of New York, read the history of two cases of Pott's disease in children, difficult of actual diagnosis.

Dr. Hodgen, of St. Louis, made some remarks on the treatment of psoas abscess for caries of the spine.

Dr. Taylor, of New York, exhibited a new form of antero-posterior splint for the treatment of Pott's disease, and a new abduction splint.

Dr. Ketch, of New York, showed a new

method of securing constant traction in using the long hip-splint.

Dr. Stillman, of New York, exhibited a new form of round-shoulder brace.

Dr. Brown, of New York, showed a case on which osteoclasis had been performed.

Dr. Bradford, of Boston, read the history of a case of torticollis due to strabismus.

Dr. Knickerbocker, of New York, exhibited a new form of abduction apparatus.

A permanent organization having been formed, the following officers were elected for the ensuing year:

President.—Newton M. Shaffer, of New York.

Vice-Presidents.—Z. H. Bradford, of Boston, and A. Sydney Roberts, of Philadelphia.

Secretary and Treasurer.—Louis Hall Sayre, of New York.

Corresponding Secretary.—Samuel Ketch, of New York.

The Association will meet next year at a place and time to be selected by the Executive Committee.

A banquet given at the St. Nicholas Club and private receptions added to the social attractions of the meeting.

REVIEWS AND BOOK NOTICES.

THE HEALING OF ARTERIES AFTER LIGATURE IN MAN AND ANIMALS. By J. COLLINS WARREN, M.D., Assistant-Professor of Surgery, Harvard University; Surgeon to the Massachusetts General Hospital; Member American Surgical Association; Honorary Fellow Philadelphia Academy of Surgery. One volume, 184 pages. Superbly illustrated with Twelve Full-Page Plates in Black and Colors. Parchment-muslin binding. Price, $3.25. William Wood & Co., New York.

In this handsomely-printed monograph Dr. Warren discusses the history of the use of the ligature in surgery, and of the various theories concerning the method of repair. He contributes the results of his own experimental and clinical investigations carried on through a series of years, including observations upon the closure of fœtal vessels, and concludes with a summary of the whole subject. The book is handsomely printed, and contains a number of well-prepared illustrations. This work is highly creditable to American surgery.

EARTH AS A TOPICAL APPLICATION IN SURGERY. By ADDINELL HEWSON, M.D. Second Edition. With Four Photo-Relief Illustrations. Philadelphia, The *Medical Register* Company, 1887. Pp. 309.

The recent advances in surgical appliances bring into discussion the *modus operandi* of former methods of treatment. The antiseptic effects of clay are now cited to explain its remarkable effects when applied to some cases of suppuration. The cases given in this book will always command for the treatment advocated a respectful consideration. It is handsomely printed and illustrated.

NEW REMEDIES AND CLINICAL NOTES.

THE POISONOUS ACTION OF THE CHLORATES.—Marchand, of Marburg, gives a number of experiments on the dog as to the effects of an overdose of the chlorates (the potassium salt being commonly used), and also a collection of cases of poisoning by the same salt. In his experiments the salt was introduced into the system in various ways. The result was the same in each case,—viz., a change in the color of the blood to a dark brown during life, swelling of the spleen, and the occurrence of hæmoglobinuria and hæmoglobin casts in the tubules of the kidney. Exactly the same takes place in man when an overdose has been administered or taken inadvertently, the lapse of time before death varying in different cases from six hours to twelve days. Death is preceded in most cases by vomiting, diarrhœa, cyanosis, and collapse. Dyspnœa and convulsions are apt to supervene, and a dark coloration of urine if the case persists any time. The changes found after death in man correspond with those found in the poisoned dog. Out of twenty-five collected cases only four survived; of the remaining twenty-one, fourteen died within the first five days. After comparing these two series, Marchand discusses the action of the chlorates on the organism, and their *modus operandi* in producing death. On examining the blood during life or after death, the coloring-matter is changed into methæmoglobin, as evidenced by the dark or chocolate-brown color of the blood and its spectroscopic characters. The coloring-matter is disassociated from the red blood-corpuscles, set free, and converted into methæmoglobin, the corpuscles being rendered functionally useless, whence the dyspnœa in some cases. The destroyed or altered red blood-corpuscles become heaped up in the spleen, giving rise to swelling of that organ; and the free pigment floating in the blood is excreted by the kidneys, producing dark coloration of urine and casts of the tubules. In some cases of somewhat slow progress cerebral symptoms allied to those of uræmia supervene from suppression of urine, due, he thinks, to plugging of the straight tubules of the kidney with hæmoglobin casts. A few of the cases of poisoning have occurred even during the ordinary use of chlorate of potassium in the form of a gargle.—*Archiv f. Exp. Path. u. Pharm.*, vol. xxii., 1886; *Practitioner.*

PICRATE OF AMMONIUM FOR MALARIAL DISORDERS.—Mr. H. Martyn Clark, a medical missionary in India, has abandoned the use of the cinchona alkaloids in the treatment of intermittent fever in favor of picrate of ammonium. Of five thousand cases of which records were kept, in only nine did it fail to cure, and in these quinine succeeded at once. In all varieties of intermittent fever and in malarial neuralgias he found this agent an efficient substitute for quinine, over which it has the following advantages: 1. It is much less expensive. 2. The dose given is much smaller (gr. $\frac{1}{8}$ to $1\frac{1}{2}$ four times a day; gr. $\frac{1}{2}$ is a fair average dose). 3. It is free from the unpleasant effects of quinine, — headache, deafness, tinnitus,—and it does not cause nausea or disordered digestion in the doses ordinarily given.—*Lancet*, February 19, 1887.

MISCELLANY.

FLAVORING OF ANIMALS.—It is suggested that a new industry might be created in the raising of poultry and various domestic animals upon certain kinds of food which will impart to their flesh new and palatable flavors. It is well known, for instance, that the exquisite savor of the canvas-back duck is due to the wild celery it feeds upon in the Southern marshes, and the delicious Congo chickens owe their superior excellence to the pine-apples they eat. The grouse of the far Western plains is aromatic with the wild sage; wild ducks and other sea-fowl have a fishy flavor; and the fish fed to swine may almost be said to be eaten over again by the consumer of their pork. Milk is especially affected by whatever is eaten, as every farmer can testify whose cows give bitter milk whenever they eat the leaves of burdock, etc. There can be no doubt that the nature of their food greatly modifies the taste and quality of the meat of most animals, and perhaps with proper effort some really valuable discoveries may be made in this direction.—*Zymotechnic Magazine*.

LEAD-POISONING. — The daily papers of Philadelphia have attributed the deaths of eleven persons to eating buns or cakes artificially colored by chromate of lead. Dr. D. D. Stewart publishes an interesting paper upon the subject in the *Medical News* for June 18, containing records of eight cases in which the poisoning was chiefly manifested by convulsions.

JEFFERSON MEDICAL COLLEGE.—The trustees of Jefferson Medical College have restored to the chair of Anatomy, now occupied by Professor William S. Forbes, M.D., the control of the surgical clinics by the following resolution:

"*Resolved*, That hereafter the duties which relate to and are connected with the holding of the surgical clinics shall be performed by the Professor of Anatomy in equal association with the Professors of the Principles and Practice of Surgery and Clinical Surgery."

DR. RICHARD J. LEVIS having announced his intention of retiring from the duties of active professional life, a number of leading professional men tendered him a public reception at the Hotel Bellevue, Philadelphia, on the 21st inst. Professor D. Hayes Agnew was Chairman of the Committee.

THE INTERNATIONAL MEDICAL CONGRESS. —The members in attendance at the recent meeting of the New Jersey State Medical Society subscribed five hundred dollars towards the Entertainment Fund, according to the daily press.

DR. WILLIAM GOODELL has removed to No. 1418 Spruce Street, Philadelphia.

OFFICIAL LIST

OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U.S. ARMY FROM JUNE 5, 1887, TO JUNE 18, 1887.

COLONEL J. H. BAXTER, CHIEF MEDICAL PURVEYOR.—To proceed to New York City for the purpose of inspecting the medical purveying dépôt at that place. S. O. 133, A. G. O., June 10, 1887.

PARAGRAPH 15, S. O. 52, A. G. O., March 5, 1887, is so amended by Par. 9, S. O. 133, A. G. O., June 10, 1887, as to direct that MAJOR CHARLES H. ALDEN, SURGEON, be relieved from duty in Department of Dakota about June 20, 1887, and he is granted leave of absence from the date when so relieved, to include August 27, 1887.

MAJOR B. E. FREYER, SURGEON.—Granted sick-leave for one month. S. O. 28, current series, Division of the Pacific, amended by S. O. 29, Division of the Pacific, June 2, 1887.

MAJOR B. E. FREYER, SURGEON.—Found incapacitated for active service by an Army Retiring Board, and granted leave of absence until further orders on account of disability. S. O. 133, A. G. O., June 10, 1887.

MAJOR W. S. TREMAINE, SURGEON.—Sick-leave still further extended two months on account of sickness. S. O. 129, A. G. O., June 6, 1887.

CAPTAIN JOHN D. HALL, ASSISTANT-SURGEON.—Leave of absence extended one month. S. O. 136, A. G. O., June 14, 1887.

CAPTAIN A. H. APPEL, ASSISTANT-SURGEON. — Granted leave of absence on surgeon's certificate of disability, for six months. S. O. 127, A. G. O., June 3, 1887.

FIRST-LIEUTENANT W. C. BORDEN, ASSISTANT-SURGEON.— Granted leave of absence for one month. S. O. 138, A. G. O., June 16, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U.S. NAVY FOR THE WEEK ENDING JUNE 18, 1887.

SURGEON THOMAS C. WALTON.—Ordered, June 15, for examination preliminary to promotion as Medical Inspector.

SURGEON A. F. PRICE.—Detached from special duty at Annapolis, Maryland, proceed home, and wait orders.

SURGEON JAMES M. FLINT.—Detached from the "Albatross" and ordered to the Smithsonian Institution.

PASSED ASSISTANT-SURGEON W. G. G. WILLSON.—Ordered to the Receiving-Ship "Independence," Mare Island, California.

PHILADELPHIA, JULY 9, 1887.

ORIGINAL LECTURES.

CLINICAL LECTURE

ON PREMATURE LABOR, AND THE MANAGEMENT OF WEAK AND IMMATURE INFANTS.

Translated for the *Medical Times* from advance sheets of the second volume of Professor Tarnier's new Treatise on Obstetrics,

BY THOMAS LINN, M.D.,

Paris.

WHEN gestation is interrupted in its usual course after the sixth month, it is called a premature labor. At present we will consider only that produced spontaneously or accidentally; artificially induced premature labor will be considered when we come to speak of obstetrical operations. The causes of premature labor, like those of abortion, are very numerous, and they need not be enumerated here. We will mention only a few of them: sexual intercourse especially is a frequent source of accidental labor; dropsy of the amnion, placenta prævia, eclampsia, also may produce labor before term much more often than abortion. In some women premature labor is a sort of habit. They are always confined before the normal term of gestation of living and healthy children, without anything being found to explain this anomaly. At times, however, there exists among them an evident hereditary predisposition, as was noticed by the old accoucheurs. De la Motte reports the case of a lady who was confined twice at seven months, and her two daughters afterwards did the same. Repetition of premature labor may also be caused by the death of the fœtus, as we have before remarked.

The diagnosis of premature labor does not present any difficulty, as its phenomena are the same as those of regular labor at term, and the delivery and after-treatment do not require special discussion. Sometimes premature labor is a happy event, in that it terminates a gestation complicated with serious accidents that have imperilled the health of the mother. In such a case it is plain that we should do nothing to prevent this favorable solution of the disorder. In cases that present themselves ordinarily, as soon as the symptoms of premature labor appear we should act as if it were an abortion, and endeavor to prevent the progress of the labor as long as the membranes are intact and the infant lives. We may use the usual means to prevent it, such as complete repose, injections of laudanum and chloral, hypodermic injections of morphine, etc. We may add that Laferla and Cazzani report that they have obtained good results by the use of asafœtida in cases of habitual premature labor. It is to be given as follows:

℞ Pulv. asafœtidæ, 6 gram.;
Syrup., 6 gram. M.
Ft. pilulæ no. lx.
Sig.—One to be taken three times a day.

However, often we cannot succeed in stopping the premature expulsion of the fœtus, and the children are then born in a state of feebleness which requires particular care. This congenital weakness is readily recognized by certain characters: one of the most important is the inferiority of weight in such children as compared with those born at full term. At the end of the ninth month of intra-uterine life the product of conception weighs from three thousand to three thousand five hundred grammes (about seven pounds), but if it is born before this period it will weigh less proportionately. A development of between eleven hundred and two thousand five hundred grammes may be called congenital feebleness. But one must base the appreciation of vitality of newly-born children not alone upon their weight, for some of them present a fair weight, but their organs are imperfectly developed. They breathe and eat poorly. Other children remaining longer in the uterine cavity may have only the same weight, and yet be fully developed, and they can breathe and digest better. The knowledge of the age of infants born before term is therefore of great value, and we should always endeavor to fix it with the greatest care. "The infant affected by congenital weakness," says Guéniot, "has certain external characters which will scarcely deceive an experienced eye, and which enable the diagnosis to be made even before having the child weighed. In such infants the organs are ill formed and the functions incomplete; the entire body is thin; the skin is soft and delicate and of a uniform bright-red color, and its transparency sometimes permits us to see the blood-

vessels that course underneath. The infant's cry is not vigorous: ordinarily it is sharp and monotonous, like the cry of the chick. The respiration is feeble and almost imperceptible. The thorax seems, so to speak, immobile, and does not present those alternations of rise and fall which are so manifest in the robust infant." The inertia of the external muscles is striking. "They hardly seem to contract, and the movements of the limbs are very rare and without vigor. The child, plunged in a sort of torpor, has not even strength enough to suck; the muscles of the mouth-walls and of the tongue and palate are apparently insufficient to cause suction, and deglutition itself is often slow,—a grave symptom, since the regular accomplishment of this physiological act alone renders life possible." A well-conducted hygienical treatment is the only means of combating this state, and it should consist in the use of heat and in a well-directed alimentation.

The action of the exterior air and variations of temperature are eminently dangerous for these little infants born before term, and they must therefore be kept in an atmosphere as warm and as equable as possible. Guéniot says "that the hand, when placed in contact with its hands, feet, or legs, and even its nose, should feel a sensation of heat equal to that of a warm bath." The newly-born child that suffers from congenital weakness must, in one word, be *penetrated with heat*, and it is only upon this condition that circulation, respiration, and all the great functions of life can go on in its frail organism.

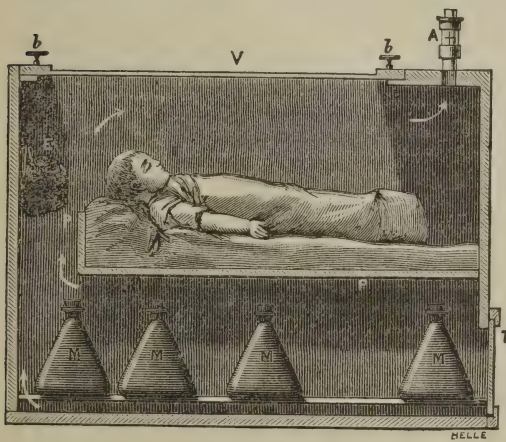
The means which have long been employed to effect this purpose are the following. The members and body are enveloped in a coat of wadding under their clothing, and a fold of cotton is placed around the head. In the cradle, two or three bottles of hot water are placed beneath the blankets, which are renewed from time to time. In changing the child, it is held before a good wood fire. In certain cases they have been kept in a room heated to 25° C. (77° F.), but it can easily be understood how difficult this is in practice. Massage is also resorted to in order to increase their circulation, and their limbs are rubbed with warm oils during five minutes, which is to be repeated two or three times in the twenty-four hours. Warm baths, in which some three quarts of wine is put, are used, and frictions with brandy, aromatic wine, lavender, etc., also have been resorted to.

In regard to the alimentation of infants born before term, the general rule is that the child is to be fed with its mother's milk or that of a wet-nurse direct from the breast. It should be well known to every one that a child may make suction-movements and yet not swallow in reality. To be sure that it has really been fed, it should be weighed both before and after nursing. If it does not swallow sufficiently, the milk is dropped into its mouth directly from the breast or given with a spoon; its meals should be given at least every two hours, and if possible every hour, *at least during the day*.

Such are the methods that have been in use for years until Tarnier's hatching-cradles were introduced, in which to maintain these infants in a constant temperature and in warm air. It was in 1857 that Professor Denucé, of Bordeaux, wrote as follows: "Having had occasion to give my care to an infant born about the sixth month of fœtal life, I found myself in presence of two indications,—to feed the child, and to keep up its temperature. To fulfil the second one I had constructed a cradle made of zinc, with double sides and bottom. Imagine, for instance, two bath-tubs, one smaller than the other, and one put within the other, leaving a space in which it was possible to put hot water: a funnel was placed at the top part, and a spigot at the bottom to draw off the water. To prevent loss of heat, the whole was wrapped round with flannel. Hot water was then put into the space between the cradles, and a thermometer gave the temperature and allowed us to keep up a regular degree of heat." In the case spoken of it was sufficient to draw off a pint of water and add as much hot water every six hours. Credé in 1884 also published an account of a similar apparatus that he had used.

Finding these sorts of incubating-cradles insufficient, Professor Tarnier had constructed one resembling a very large hatching-machine, which was erected at the Maternity Hospital, Paris, in 1880. The temperature was maintained at 32° C., according to Tarnier's advice, and Dr. Budin had a Regnard's regulator adapted to it, with electric alarm-bell. We will not describe this machine, as it was large and

costly, but M. Tarnier has recently had made a small apparatus suitable for family use, which is very simple and easily managed; it can be made by any carpenter at very little expense. "It is a box made of wood, sixty-five centimetres long by fifty high and thirty-six wide, and the sides are twenty-five millimetres thick. The inside of the box is divided by a partial partition into two parts; this horizontal partition is placed about fifteen centimetres from the bottom of the box. The lower story is intended for some hot-water bottles, such as are called 'monks' in Paris." (They are simply earthen hot-water bottles, with a flat side, and the hole for the cork on one side.) The wood-cut shows the apparatus.



There are two doors: one is a sliding door on the side of the box, to push to either side for the purpose of introducing the hot-water bottles; the other is at one of the ends (at T in the figure); it does not completely close the orifice, but allows air to enter. The upper part, for the baby, contains its bedding, and is covered with a glass top at V; it should close as tightly as possible with two screws at *b b*. At A is an outlet for the air, to which a small ventilator can be attached. In the opening between the two chambers a wet sponge is placed to keep the air slightly humid, and a thermometer is also placed here to mark the temperature. The heating arrangement is the earthenware jugs at M; they are twenty centimetres long, and contain a pint of water; four or five of them are used to keep the temperature to 31° or 32°. It is heated to this degree before putting the child in, and every one and a half to two hours one of the hot-water bottles is changed for a fresh one. The air passes in by the little trap at T, is heated by the bottles, and, passing by the sponge at E, escapes at A. The movement of the small ventilator at A will show that air passes.

The child should be put in swaddling-clothes, as it has been observed that the temperature is always two or three degrees higher under the clothes than it is in the hatching-machine. It should be from 32° to 33° in the apparatus. Every hour or two, according to the case, the infant should be taken out to feed and change it; but it should only be kept out the shortest time possible. The excellent action obtained by such cradles is shown by the results obtained at the Maternité in Paris. It should be added that infants who are attacked with sclerema, œdema, cyanosis, etc., also derive great benefit from being placed in the hot cradle, and often twenty-four hours will be enough to bring about a decided improvement. Œdema of newly-born infants disappears with surprising rapidity when they are placed in the machine for a short time. From 1877 to 1880, before it was used, one hundred and eighty-one infants died at the Maternité with sclerema; from 1882 to 1885, with the use of the hatching-machine, only nine died.

Since the incubating-cradle has been used, Winckel has advised the use of prolonged warm baths; but we fear it would be difficult to adopt this in practice.

The following table gives the statistics of the Maternité of the number of infants put into the couveuse:

Weight of Child.	No. of Infants.	No. who Lived.	No. who Died.
1000 to 1500 grammes	40	12	28, or 70 per cent.
1501 to 2000 grammes	131	96	35, or 26.7 " "
2001 to 2500 grammes	102	101	11, or 9.8 " "

At the Maternité, before the introduction of the machine the infants died at the rate of sixty-six per cent.; since employing the heated cradle the average proportion is 36.6 per cent.

Credé also obtained good results with his incubating-cradle; but his rate of mortality was much higher than Tarnier's. In the lowest weights he lost 83.3 per cent.; in the next, fifteen hundred to two thousand grammes, 36.5 per cent.; and, taking the

total, he lost 44.6 per cent., and some of his patients were over the weights given by Tarnier, who does not put the heavier children in the hatching-cradle.

Alimentation.—This is a question of the greatest importance in children who are born before term, and Professor Tarnier has adopted a method that we will describe in full. From the very first day an attempt must be made to put children to the breast, and if they are too feeble to suck, the milk may be squeezed into the mouth, or at first on a warm spoon and then given to the child. The mother's or nurse's milk, given pure without dilution or addition, is the best of all things for these infants; but if it cannot be had, then it may be replaced by asses' milk, *not boiled*, but mixed with warm sugared water in equal parts (three grammes of sugar to one hundred grammes of water). If asses' milk cannot be had, then cows' milk must be used for want of a better, and the mixture to be made is then one quart of cows' milk to three quarts of the sweetened water as above. The cows' milk is better boiled; and that boiled in a water-bath closed up is better than boiled in the open air. It is best of all prepared as follows: The mixture of milk and sugared water is put into what is called the "American pot" (which is an air-tight pot used to make beef-tea in); it is then put into boiling water for half an hour, and when taken out the contents should be turned out to prevent the liquid having a metallic taste. It is given to the child with a small spoon, and when the infant is very small six to eight grammes of liquid are enough for a meal, but this may be carried up to ten or fifteen grammes when the infant is larger. There should be at least twelve meals in the twenty-four hours.

"*Gavage.*"—It will often happen that the child will drink badly and throw up half of the liquid given, and, the alimentation then being insufficient, it gets rapidly worse, diminishes in weight, and frequently has diarrhœa, and it is in these cases that Dr. Tarnier practises what he calls "gavage." The apparatus used is quite simple, being nothing more than a urethral sound of red rubber (No. 14 or 16 French according to Charrière). At the open end of the sound is attached a glass nipple, sold in the shops under the name of Dr. Boilly's glass nipple. (A small glass funnel would do.) With this it is easy to use the forced feeding system called "gavage." The infant is placed on the knee, with its head slightly raised; the sound is made wet and introduced as far as the base of the tongue, and the infant by its instinctive attempts at deglutition will make it go on as far as the œsophagus. The sound must be then gently pushed down the œsophagus, and it will readily pass into the stomach. The milk or liquid is then poured into the glass funnel, and by its weight will soon find its way down, and will empty into the stomach. After a few seconds the sound must be taken out, and here is the great point of the system: *it must be taken out with a rapid motion at once,* for if it is withdrawn slowly the milk given will be thrown up after it. The number of meals thus to be given will vary with the age and strength of the infant. As a general rule, eight grammes of milk given every hour will be enough when the infant is small, to be increased as needed. As to the aliment to be used, it is the same as in the usual alimentation. Professor Tarnier gives the preference to mother's milk, which they can press into the glass funnel used. It failing, the other milks may be used as stated before.

When the "gavage" is too copious, a curious phenomenon is produced: the infant augments rapidly in weight and in volume, but it is due to an œdema of the whole body, and, as this will disappear with a more moderate alimentation, it can be explained as a hypernutrition. But if, instead of diminishing the quantity of food, it is maintained or increased, before long indigestion will set in, and the child may perish with gastritis and enteritis. This is the great danger, and success is only obtained by giving the milk in very small quantity and often repeated. When the "gavage" is well done and the milk is not vomited, the infant will digest it well. The fæces are yellow in color, and the child will increase in weight.

When the new-born child gets to be a little stronger, this mode of feeding can be alternated with nursing, and so on progressively until the "gavage" is given up entirely; but it should be resorted to at the least sign of digestive trouble. Even when the child is old enough to nurse, should it be at all weak, it is useful, outside of its regularly taking the breast, to practise "gavage" three or four times a day. This is what M. Tarnier calls *gavage*

de renfort, as it will keep up the strength of the child so that it can take the breast and digest well.

Notwithstanding that this method of gavage is still being studied, from the results at the Maternité and those of lying-in wards in the hospitals in Paris it can be said that it is clearly indicated when the infant is born before term, and even if it does not possess the sensation of hunger, or lacks the necessary strength to eat, it is just the same as with the adult: the food introduced artificially into the stomach of the new-born infant will be digested.*

Thanks to the employment of the two methods of "gavage" and the Tarnier hatching-machines for the last few years, infants were raised that had been only six months, or six months and a few days, carried in the uterus. So that at last the actual period of vitality has approached the legal period, which in French law is six months of intra-uterine life. So far very few six-months' children have been saved in France.

ORIGINAL COMMUNICATIONS.

ON PLACENTA PRÆVIA.

Read before the Oxford Medical Society

BY C. P. JACKSON, M.D.

BY placenta prævia is meant that condition of affairs where the placenta is attached to the lower segment of the uterus, covering either partially or completely the os uteri; or, it may be, only coming down to the edge of the cervix.

This accident of pregnancy was known as early as the time of Paré,—in the beginning of the sixteenth century. Guillemeau, Mauriceau, Deventer, Pugh, and others were all acquainted with the fact that the placenta was sometimes found at the os uteri; but they supposed that in these cases it had become detached and had fallen down from its normal situation. Paul Portal was the first who had any accurate knowledge of the subject and recognized the necessity of delivering by art. To him undoubtedly belongs the honor of the original discovery of this abnormal insertion. In his work, which appeared in 1685, he described six cases in which "the placenta presented, was in entire contact with the orifice of the womb, and was adherent throughout." After the time of Portal his discovery appears to have been lost, and the "great obstetrical lights of the eighteenth century" (as Thomas calls them) had to grope their way to the truth. Deventer was among the number who, having noticed that the placenta still adhered by one margin to some point of the periphery of the cervix, considered the adhesion to be only accidental, and merely caused by clotted blood. He was not far from the great discovery, however, when he said, this "sometimes glues the placenta so closely to the orifice that it might be mistaken for an excrescence of the part."

Giffard, Roederer, Smellie, and Levret, in the middle of the century, almost simultaneously rediscovered Portal's discovery. To Dr. Rigby, of Norwich, however, belongs the credit of clearly and fully elucidating the subject. From him we have received the term "unavoidable hemorrhage."

This accident, in common with most other ills to which human flesh is heir, has been ascribed to various causes by different observers. Tyler Smith supposed it to be due to the ovule not having been impregnated until it reached the lower part of the uterine cavity. This is the view that Dr. Penrose holds, or did hold a few years ago. As proof of this, I remember his bringing forward statistics of the Jewish people, who, if the theory were true, should furnish an unusually large proportion of such cases, on account of the restrictions of the Levitical law. This he proved to be a fact, I believe.

Cazeaux inclines to the opinion that the mucous membrane is less swollen and turgid than when impregnation occurs at the proper place, and therefore offers less obstruction to the descent of the ovum. Schroeder also says an abnormal smoothness of the uterine wall caused by a previous leucorrhœa may be the occasion of the accident. Age has been advanced as a probable cause of the mishap under consideration. In the statistics of two hundred and forty cases of placenta prævia collected from the physicians of the State of Indiana by Dr. Enoch W. King,† the

* Professor Tarnier has lately tried a mixture of asses' milk in equal parts with meat soup, but the experiment is too new yet to detail it. However, the results are encouraging when the child cannot digest and has diarrhœa.

† See Amer. Journal of Obstetrics, October, 1880.

ages of one hundred and fifty-seven only are given. These he has classified in five-year periods. From his table we find that the largest percentage of cases occurred in the five-year period from twenty-six to thirty; but nearly as large a proportion occurred in each of the periods from twenty-one to forty inclusive, amounting in all to about ninety-two per cent.

Now, if it be true, as has been stated, that about nine-tenths of all obstetric cases occur within this limit, we are justified, I think, in the conclusion that age has little influence in the causation of this troublesome complication of labor.

Another cause which is said to predispose to unavoidable hemorrhage is an abnormal size of the uterus. Hence the greater frequency after several pregnancies. Playfair inclines to this theory, but Dr. Harris, in editing the last American edition of Playfair's "System of Midwifery," says, "The belief in the greater frequency after several pregnancies is not well founded." And these are the grounds for his objection:

Dr. King reported one hundred and eighty-three instances where the pregnancy at which the placenta was prævia is stated. In the first pregnancy there were ten per cent. of cases; in the second, sixteen per cent.; in the third, sixteen per cent.; in the fourth, eleven per cent.; in the fifth, fourteen per cent.; in the sixth, ten per cent.; in the seventh, eight per cent.; in the eighth, five per cent.; and in the ninth, two per cent. This really begins to look as though Dr. Harris were right. But in Simpson's obstetrical works there is a table (cited by King) giving an approximation of the percentage of deliveries which occurs in each pregnancy. This estimate is thirty per cent. of deliveries for the first pregnancy; while we have seen from King's report that the cases of placenta prævia amount to only ten per cent. for the corresponding pregnancy. Following out the comparison of the two tables, we find that, though there is a gradual falling off in the percentage of placental presentations as the number of the pregnancy increases, there is a still greater diminution in the proportion of deliveries. Thus, it is not until we reach the third pregnancy that the percentage of abnormal placental insertions exceeds the proportion of deliveries, and then only by one per cent.; while in the sixth pregnancy the cases of placenta prævia amount to ten per cent., the deliveries to only five per cent.; in the seventh pregnancy, placenta prævia eight per cent., deliveries three per cent., and so on; thus, in the language of Dr. King, "quite conclusively showing that placenta prævia *does more generally occur in women who have borne several children.*" So far at least as any practical results are concerned, we are as far from the truth of the matter as were those inquirers at the beginning of the sixteenth century, the simple fact remaining that once in five hundred or six hundred cases the placenta is grafted either partially or completely over the external orifice.

Although the previous placenta of necessity occupies its site from the first moment of its formation, it rarely gives rise to any appreciable symptoms before the last three months of utero-gestation. It is probable, however, that an abnormal insertion sometimes produces abortion in the earlier months of pregnancy without its site of attachment having been suspected. The first symptom which causes suspicion is the sudden occurrence of hemorrhage without any appreciable cause. The amount of blood lost varies considerably. The first hemorrhage may be slight, in some instances ceasing spontaneously, only to recur, however, after a varying interval,—it may be a few days or it may be weeks,—each successive hemorrhage being more profuse. Hemorrhage seldom occurs before the end of the sixth month, often not until the ninth, and it may not occur until labor has commenced. Flooding is very liable to make its appearance on what would have been a menstrual period, probably on account of the physiological congestion of the uterus at that time. Should the first loss not show itself until near full term, it may be so great as to put the patient in imminent peril of death before assistance can be procured. Indeed, when hemorrhage has once occurred the patient is never safe, for excessive losses may occur at any moment when professional aid is not at hand.

An increased flow of blood during the pains of labor has long been looked upon as a diagnostic mark by which to distinguish between unavoidable and accidental hemorrhage; but, according to Playfair, "this distinction is altogether fallacious."

Though the pains do to a certain extent augment the sanguineous flow by detaching fresh portions of placenta, yet the immediate effect of the contractions here, as in all other forms of uterine hemorrhage, is to constrict the lacerated vessels and so lessen the flow, the apparently increased flow being due to the forcing out of blood which has already escaped from the vessels. Once our suspicions have been aroused by unaccountable hemorrhage, a vaginal examination becomes imperative.

If the os be sufficiently open to admit the finger, as it usually will be on account of the relaxation caused by the depletion, we shall usually be able to make out some part of the presenting placenta, though, if the os be high and gestation not far advanced, it may be necessary to insert the whole hand into the vagina. If the implantation be central, we shall find the os covered with a boggy mass more dense and less friable than a coagulum, yet offering less resistance to the finger than a fœtal presentation; in short, we shall find conditions presenting the digital eye of the explorer with a scene altogether characteristic of the accident under consideration. If the insertion be lateral, the bag of membranes, and above it the presenting head or other part of the fœtus, will be found occupying a part of the circle of the os, the rest being covered by the placenta. The lower portion of the uterine ovoid may in some cases be found unusually thick, and, according to Gendrin, ballottement cannot be made out. Doubtful cases may be cleared up by finding the placental bruit over the lower uterine segment. Dr. Wallace has even gone so far as to propose vaginal auscultation by means of a curved wooden stethoscope.

The source of the hemorrhage has long been a moot point. Sir James Y. Simpson maintained with much energy that the source was the detached portion of the placenta; that the blood flowed from the adherent into the detached portion, and escaped from the surface of the latter. Drs. Radford, Kinder Wood, and others held the same opinion, and on this supposition based their plan of complete separation of the placenta. That hemorrhage usually ceases on complete separation of the placenta is not doubted, but Simpson's explanation of it is contested by most modern writers, especially by Barnes, the success of *his* modification of this plan clearly proving the fallacy of Simpson's theory. Furthermore, Dr. Mackenzie proved beyond doubt, by a series of experiments in which he partially separated the placentæ in pregnant bitches, that the blood flowed from the uterine wall, principally from the large venous sinuses, the arrangement of which specially favors hemorrhage when torn across, and possibly to some extent from the uterine arteries, just as in post-partum hemorrhage after the placenta has been entirely detached.

The cause of the hemorrhage has also been the subject of much discussion and difference of opinion. The earlier observers of this accident ascribed it to separation of the placenta from expansion and retraction of the cervix during the latter months of gestation,—an instance of good logic from false data, the shortening of the cervix being only apparent, not real. The theory of Jacquemier (endorsed by Cazeaux) supposes a loss of relation between the cervix and the placenta. He maintains that during the first six months of pregnancy the superior portion of the uterus is more especially developed; that the placenta also attains its maximum of development in the same time. So, when attached in its usual situation, there is no loss of relation in the development of the organs. On the other hand, during the last three months of pregnancy the lower segment of the uterus is more especially developed, while the placenta remains nearly stationary; thus, when attached to the cervix, the cervix grows away from the placenta. Barnes's theory differs from this in that he supposes the loss of relation to be due to an excess of growth of the placenta itself over that of the cervix during the latter months, the objection to both these theories being that hemorrhage often does not take place until labor has begun.

Playfair says that uterine contractions are constantly occurring during the continuance of pregnancy; that there is reason to suppose that these do not affect the cervical as well as the fundal portion of the uterus; that in cases where the placenta is placed either partially or completely over the os, one or more of these contractions, stronger than usual, may produce laceration of the placental attachments in that neighborhood. While Matthews Duncan claims that the causes

of hemorrhage in placenta prævia are precisely the causes that give rise to the occasional hemorrhages when the placenta is normally placed; that before labor has actually commenced the losses are strictly accidental; and that it is only at full term that they can with propriety be called unavoidable.

In the onward march of medical science the faithful follower of Hippocrates should not be confused by the din of conflicting theories; but at every cross-roads and at each divergent path let his eye be fixed on that deft though silent guide, nature.

Let us see, then, what are the ways in which nature seeks to relieve the unhappy victims of this accident. Of the cases reported by King, nearly forty-eight per cent. were spontaneously premature, with a mortality to mothers of fifteen per cent.; while the mortality in his entire collection was twenty-two and a half per cent.

Now, if it be understood that these favorable results were obtained without the patient's having been from the beginning under the careful supervision of the medical attendant, and that in many instances nature was only aroused to action after the woman had been debilitated by repeated losses of life's fluid, it will the more clearly appear how strong is the indication to follow nature; and yet, so far as I can learn, the medical world at large has given little attention to this most important point. Let us take a view of the surroundings. Here we have an appalling calamity, the mortality from which is about as great as that from the capital operation of ovariotomy. Can there nothing be done to render our prognosis more favorable in these cases? What *has* been done in the centuries past? Says Dr. Robert Lee, in 1845, "The most distinguished practitioners, from the days of Ambroise Paré to the present time, have universally recommended and practised turning in placenta prævia." What was the result? Simpson published a table of three hundred and thirty-nine cases collected from the records of a dozen or more such eminent men as Mauriceau, Gifford, Smellie, Rigby, Ramsbotham, Lee, etc., in which the mortality was one hundred and thirty-one, or about one in three.

It is true that Lee accuses Simpson of "several great inaccuracies" in his table, and also of omitting to mention Portal's eighteen cases (seventeen of which were delivered by turning) with only one death. But how shall we account for Portal's success? Was he, in the seventeenth century, so vastly superior in obstetric skill to all his followers down to the nineteenth century? or had he made some other discovery (lost to his successors) to which his success was due rather than to the mere operation of version? However the case may be, until within the last decade at least there have been no statistics, so far as I know, which could approach to his in benignity of results.

It is true that Simpson published (in the *London and Edinburgh Monthly Journal of Medical Science* for March, 1845) a collection of one hundred and forty-one cases in which the placenta was detached and expelled before the child, with a mortality to the mother of ten, or one in fourteen. This is a higher death-rate than that of Portal, but, compared with other statistics, it still makes a most excellent showing. It has this disadvantage, however: these were not consecutive cases occurring in the practice of one or more physicians, but they were collected from here and there through the whole field of obstetrical literature for the purpose of proving a pet theory, and the chief objection to their reception is that most if not all of these were cases in which there were strong expulsive efforts on the part of the mother, and nature was quite able to take care of herself without the intervention of art. Such statistics are not worthy of full credit; and the test of years has not realized the enthusiastic hopes of Sir James Simpson. The treatment of these cases, as laid down in the various obstetrical text-books, is something on this order: on the occurrence of hemorrhage, having made a diagnosis of placenta prævia, place the patient on a hard mattress in a cool, well-ventilated room; do not heat or overburden her with clothes; keep her absolutely at rest; administer cool, acidulated drinks, with acetate of lead and opium or gallic acid; apply cold cloths, or even ice, to the vulva, lower part of the abdomen, and thighs,—in short, temporize until labor be forced upon you, then plug the vagina while the os dilates, give ergot if you please, and as soon as practicable or safe rupture the membranes, detach the placenta, or deliver by turning or the forceps, according to your preconceived notions or the nature

of the case. What are the results of this mode of procedure? According to different authorities, one in every three, every four, or every five, mothers perishes, while more than one-half of the children are lost.

According to King's statistics, the mortality from all methods, taken as a whole, was twenty-two and a half per cent. The mortality from all cases treated by ergot was sixteen per cent.; by rupture of the membranes, eight per cent. (these were nearly all favorable cases); by complete detachment of placenta, eighteen per cent. (but here seventy-seven per cent. of children were lost; by tampon, twenty-five per cent.; by forceps, thirty per cent.; by version, twenty-three and a half per cent. Thus have all these measures been weighed and found wanting! Can the skill of man devise nothing that shall lessen the mortality of this fatal accident?

In 1837 Dr. Renton wrote, "Portal in 1672 knew as much on the subject of uterine hemorrhage occasioned by displacement of the placenta from the os uteri, and of the practice necessary for its suppression, as we do at the present time."

In 1837 this was true: in fact, it was less than the truth. In the light of our present knowledge, I ask, Did he not know more?

Hitherto I have only spoken of the treatment of placenta prævia when it is thrust upon the physician in all its horrors,—perhaps at full term, when the uterine sinuses are prepared to send forth a terrible deluge of blood; or, it may be, after the patient has been exsanguinated by small, though repeated, losses; after the well-meaning but ill-advised efforts of the physician have kept the poor victim in a darkened room for weeks or months (through some imaginary benefit that is to accrue to mother or child), until her vital powers have reached so low an ebb as to be unable to survive the shock of labor. But, thanks be to those lights of our profession who have not forgotten to look up to and follow in the footsteps of Mother Nature, a better state of things has begun to be inaugurated! Cure the wretched evils proceeding from this insidious enemy, when given full sway, we cannot; crush them in their incipiency, in great measure, we may.

Induction of premature labor as a prophylaxis of placenta prævia was first introduced into practice by Dr. Robert Greenhalgh, of London. In 1864 he read a paper ("Practical Remarks on the Treatment of Placenta Prævia") before the Obstetrical Society of London, in which he strongly advocated this mode of treatment.

Drs. Barnes, Hicks, Hewitt, Beatty, and Oldham all took part in the discussion which followed, and it would appear from their remarks that they were all more or less familiar with the practice he recommended, several of the gentlemen stating that the principle had been admitted by men of experience, but had not been laid down in the obstetrical text-books, while Dr. Beatty said there was not much difference between Greenhalgh's practice and the usual practice in Dublin. "And yet," says T. Gaillard Thomas, "I know of no work, essay, or text-book which gave this advice at any time previous to the appearance of Greenhalgh's paper." Let us see what are the results of this practice. The statistics are few, and therefore may be misleading, but so far as they go they are certainly very encouraging.

In an excellent paper on the subject (see *American Practitioner*, vol. xv.), Dr. Thomas reports eleven cases in which he induced labor by means of Barnes's dilators on the first occurrence of hemorrhage. He speaks of three of his patients as being primiparæ, of seven as multiparæ, and of one he speaks somewhat ambiguously as a young woman. Six children (an unusually good average) and all the mothers but one were saved. Case IX., a multipara, died on the fourth day after delivery, of septicæmia. Since this can hardly be looked upon as a direct effect of placenta prævia, I think we may regard this as a report of eleven consecutive cases without a single death.

From a careful study of the foregoing facts and figures I arrive at the following conclusions:

1. Having been summoned to attend a case of ante-partum hemorrhage, it is necessary to make a most thorough examination as to its cause.

2. Supposing the diagnosis of placenta prævia has been made, it is the duty of the physician to ascertain whether the child be viable: if not, the mother's physical condition warranting, and her domestic relations and pecuniary status not positively contra-indicating, temporize until the child arrive at the age of viability.

3. The child being viable, induce labor at once, and so protect the patient from the danger of sudden, exhausting, and, it may be, fatal hemorrhage. The induction of labor is best brought about by the use of hydrostatic dilators, preceded, if need be, by a sponge-tent.

The os being well dilated, complete labor by rupture of the membranes, version (using bimanual method if possible), the forceps, or separation of the placenta, according to existing conditions and the necessity for expedition.

Oxford, Chester County, Pennsylvania.

THE BACILLUS TUBERCULOSIS AND THE BUSY PRACTITIONER.

BY J. L. ELLIOTT, M.D.,
Bay City, Michigan.

EVER since the discovery of the bacillus tuberculosis by Koch there have been many who doubted whether any practical benefit would be derived from the discovery. But after five years' quite extensive experience with the bacillus and its relations to tuberculosis, the most advanced thought and highest authorities in the medical profession tell us that there is a definite relation between them. These authorities are widely at variance as to whether the bacilli are the cause or only an accompaniment of the disease. They are, however, pretty well agreed upon two points,—viz. :

1. That when the bacilli are present in the sputum they become positive evidence that such sputum comes from a tuberculous centre.

2. That their number, when present, is as index of the rapidity with which the disease is progressing.

It is to be regretted that there is any chance for disagreement upon the question, but that should not deter us from putting to practical use the settled points, leaving the other for future investigation to decide.

Now, if the doctrines as taught us are correct, every practitioner of medicine should be able to stain and recognize bacillus tuberculosis. The writer is satisfied, however, that altogether too few practising physicians make any use whatever of the microscope as an aid in the diagnosis and prognosis of tuberculous disease, and it is this very fact which has prompted the writing of this article. It has been for some time apparent to workers in this field that the whole bacillus tuberculosis question stood in need of a practical turn,—that is, it should be shorn of so much technicality, and brought within the range of the every-day busy practitioner. For if the discovery of Koch is of practical importance to mankind, it can only be made manifest by practitioners of medicine acquiring a knowledge of the subject sufficient to enable them to make practical use of it.

Heretofore the methods of acquiring this knowledge have been accompanied by difficulties which professional microscopists do not seem to overcome. Physicians engaged in the practice of medicine who seek for information upon any topic pertaining to their profession must, in most cases, rely upon current medical literature. Now, we all know this country is flooded with the latter, of uniformly good quality too, yet the writer must confess that nearly every article on staining and identifying bacillus tuberculosis with which he is familiar has certain defects which must certainly limit its usefulness. There is too much technicality for physicians in general to follow understandingly. The illustrations usually represent the bacilli magnified eight hundred or twelve hundred diameters, which gives them an appearance altogether unlike that seen by the aid of the low powers. The staining process described is tedious, requiring two to twenty-four hours to execute. Nothing is said of the expense of equipping one's self for the work, or how to obtain chemicals of reliable quality. So that the process as usually described is so complex, tedious, and indefinite that no doubt many are discouraged at the outset, and many more, to his certain knowledge, fail to get any results at all when they attempt to execute the work as described. Some microscopists, who habituate themselves to the use of high powers, many accessories, etc., seem to entertain the belief that simpler methods will not give just as good results. For instance, Dr. Formad, an eminent pathologist and microscopist, in his series of articles on the bacillus tuberculosis question, says the following: "The second advantage resulting from the bacillus theory may be that physicians may become induced to make more use of the microscope in diagnosis; yet in this respect the general use of the microscope is hardly

practicable, on account of the thorough technique and experience required."*

The writer does not wish to criticise this class of teachers: with them scientific accuracy and its accompanying technique are second nature, and their work is very important to scientific medicine. It is unfortunate, however, for the profession that the subject is kept in such a complex state. The writer claims that the process may be so simplified that, with a little skill and very moderate outlay for apparatus, any physician can determine the presence or absence of bacillus tuberculosis in sputum, and that, too, in as short a time as fifteen or twenty minutes. This may be accomplished by observing the following details.

The Microscope and Accessories.—Any ordinary stand will do, as long as the fine adjustment works well; a high-power objective is not necessary at all. The writer has been surprised to find so many able workers with the microscope who claim that a high-power objective is indispensable. A friend who served a term in hospital, where he had every facility for such work, and thereby gained a large experience in staining bacilli, wrote after he began to practise medicine that he did nothing in the way of staining bacilli since leaving the hospital, because he had no high-power objective. For all practical purposes, a good one-quarter inch glass (Spencer's students' series, for instance) is all that is needed; a one-sixth inch is a little nicer, but it is not necessary. The writer has even been able to see the bacilli with a first-class Spencer's one-inch objective.

With his one-fourth inch objective he uses a one-inch ("C") eye-piece. Now, a great many physicians have a fairly good stand and the above-named glasses, and yet they do not stop to estimate whether they have the requisite power to identify bacillus tuberculosis.

Staining and Mounting.—There are quite a variety of methods: some comparatively simple, others quite tedious and complicated. The one best suited to the use of the physician is the one which is perfectly reliable, and at the same time quickly executed. The writer has tried many methods, but the one he is about to describe is the one which has proved to be most reliable.

The apparatus needed are a light pair of forceps, a spirit-lamp (or Bunsen burner), a beaker glass (or tumbler), a watch-glass, bottle of glycerin, slides, and cover-glasses. Nearly every physician has these already on hand. The chemicals needed for staining are a saturated solution of aniline oil in water, a saturated solution of fuchsine in alcohol, a two-per-cent. solution of hydrochloric acid in alcohol. Now, few retail druggists will be apt to have the aniline oil and fuchsine in stock, but they may be ordered from Messrs. Lehn & Fink, importers, of New York, in a short time. It is very important to have these two chemicals of first-class quality, or else no results will be attained, and the writer feels thus in duty bound to mention the above-named firm on this account, knowing they would send out no inferior goods. The necessary quantities of the above-named solutions one would need to work with should not cost over seventy-five cents or one dollar, so that the whole outlay for working material is only a trifle.

The process is applied as follows. Try to obtain a thick portion of sputum which the patient has coughed up from the lungs. Spread a thin layer on a cover-glass and allow it to dry. Some difficulty may be encountered in spreading a thin layer of sputum evenly over the cover-glass; a little practice by the following method will give good results: place with forceps a small portion of thick sputum on the centre of the cover-glass; next press the cover-glass with the sputum against a glass slide; this will flatten the sputum out into a thin layer; now draw the cover-glass away from the slide, always keeping their surfaces parallel while doing so. Next pour a watch-glass nearly full of the aniline-oil solution, add to this from five to ten drops of the fuchsine solution; next lay the cover-glass, sputum side down, on the surface of the staining solution. Now hold the watch-glass containing the stain and cover-glass over the spirit-lamp and heat gently for three or four minutes; the degree of heat needed here is just sufficient to cause vapor to rise from the liquid. Remove the cover-glass from the stain. Wash away the excess of staining solution with water, then wash in the hydrochloric-acid solution until decolorized or nearly so; wash again in pure water, touch the edge of the cover-glass to blotting-paper to remove the excess of water, then lay upon blotting-paper and allow it to dry.

* Philadelphia Medical Times, vol. xiv. p. 337.

Place a drop of glycerin on the centre of a glass slide; heat it a little to remove any air-bubbles which may be present; place the prepared cover-glass carefully on the slide, and allow the glycerin to spread out and form a thin layer between slide and cover-glass. Right at this point a little patience and experience will be required sometimes, when it is desired to make a permanent mount, to get the exact amount of glycerin necessary to spread to the edge of the cover-glass, and no more. A little experience will soon enable one to estimate pretty accurately the size of drop required. Should too much be used, the excess can be removed from the edge of the cover-glass with strips of blotting-paper; should too little glycerin be used, a drop placed at the edge which lacks enough will flow under the cover-glass and meet the portion first used.

The slide is now ready for examination. If bacilli tuberculosis are present in the sputum stained, careful focussing will show them distinctly as dark-colored, curved, slender rods. When the bleaching process has been incomplete, so that the epithelial cells, pus-corpuscles, and débris of broken-down lung-tissue all retain the coloring-matter, the bacilli are still easily seen, being darker in color and more regular in outline.

One more point the writer wishes to call attention to. He has frequently failed to find any bacilli whatever after making several mounts; then, from the same lot of sputum, a portion from another part of the dish would be tried and the bacilli found in great numbers: so that before one can exclude their presence samples must be tried from all parts of the containing dish.

If it is desired to preserve the slide, a ring of zinc-white cement can be run on the edge of the cover-glass, and the mount will keep indefinitely.

[Dr. Elliott has kindly sent us a slide prepared in the manner described, which certainly leaves nothing to be desired: it could not be surpassed by any method.—Ed. *P. M. T.*]

Chronic Constipation.—The rational treatment of chronic constipation consists, according to Dr. J. K. Spender, in avoiding powerful purgatives, administering aloes and iron, and an occasional saline, with a liquid diet and exercise.—*The Practitioner.*

REPORT ON RECENT STUDIES ON DISEASES OF THE CIRCULATORY APPARATUS.

BY J. P. CROZER GRIFFITH, M.D.

THE PULSE.

Broadbent, in the Croonian Lectures (*British Medical Journal*, 1877, 655, 707, 763), says the pulse is with propriety taken at the wrist because the circulation of the hand is not affected by disturbances of special function. The pulse is not produced by an expansion of the artery, as is so often taught, nor by an elongation of the vessel throwing it into curves. The real cause is a sudden change of the artery from a flaccid and somewhat flattened condition to a cylindrical shape. This is brought about by the increased pressure from ventricular contraction. Nor is it the case that the pulse indicates an onward flow of blood through the vessel, or that the strength of the pulse is proportionate to the rate of movement of the blood. It is simply a record of the minimum and maximum pressure, with the degree of difference between them.

There are three factors in the production of the pulse:

1. *The action of the heart.*
2. *The elasticity of the great vessels.*
3. *The resistance of the arterioles and capillaries.*

1st. The first of these determines absolutely the frequency and regularity of the pulse, except in cases where there are more heart-beats than appreciable pulse-waves. The strength of the pulse, too, will depend on the power of the systole combined with the volume of blood entering the aorta.

2d. The second factor converts the intermittent jet of blood into a more or less continuous stream. Dicrotism of the pulse is produced by the elasticity of the great vessels, especially when combined with low tension of the peripheral circulation and a sharp contraction of the heart. High arterial tension or inelasticity of the great vessels from degenerative changes is incompatible with the occurrence of dicrotism.

3d. The third factor possesses the greatest influence on the character of the pulse. Together with the force of the heart, it determines the *mean tension* in the arterial system, measured by the degree of resistance of the artery between the pulse-beats.

The higher this mean tension, the less the difference between the maximum and minimum tensions,—*i.e.*, the less marked is the pulse. And the converse of this is of course true.

The author then enters upon the consideration of the variable tension—the pulse. Although he admits the advantage of the sphygmograph in many instances, yet it is liable to so great irregularity in the tracings it produces that he confines himself chiefly to the consideration of the pulse as it is perceived by the finger. When there is but little resistance in the peripheral vessels, the pulse is sudden and sharp, and of short duration; while with high tension the pulse-wave rises gradually and is of longer duration. This prolongation of the pulse-wave must not be confounded with the fulness of the artery between the beats.

In a systematic examination of the pulse it is necessary to notice:

(1) The *number* of beats per minute, their *regularity* and *equality*.

(2) The *size* of the artery. This is very variable in different persons, the difference being either congenital or induced by physiological or pathological influences. A large artery communicates a more perceptible impulse to the fingers touching it lightly, and the beat is stronger; but the pulse-wave can be more easily stopped by pressure. In a small vessel the impulse may seem weak, but often grows stronger when compression is attempted.

(3) The degree of constant pressure,—*i.e.*, the *tension*. This is tested by trying to roll the artery under the fingers. In a pulse of average tension the vessel seems to stand out only during the actual beat, and subsides gradually, though it may generally be distinctly felt between the beats. If the tension is low, the vessel can scarcely be felt at all except just at the moment of the beat. In high tension, the artery can be plainly seen and rolled about under the fingers. Yet the pulsation in it is often scarcely perceptible except under firm pressure.

(4) The *character* of the pulse: whether its access is sudden or gradual, its duration short or long, and its subsidence abrupt or slow.

(5) The *strength* of the pulse. This is estimated by placing three fingers (as always) upon the artery, and with the one or two nearest the heart determining what degree of pressure must be exerted to obliterate the pulsation felt by the other finger.

(6) *The state of the arterial walls*. This may be examined either by rolling the vessel or by carrying the skin along it longitudinally in search of inequalities, curves, calcareous patches, etc.

(7) *Dicrotism;* which is tested by allowing the fingers to rest with uniform, gentle pressure on the vessel. The physiological dicrotic wave will be felt like an echo of the principal one.

There seems to be no constant relation between differences in the circulation and the bodily or mental character, and even modifications of the circulation in disease are oftener the effects than the cause. It would be impossible to consider all the indications afforded by changes in the pulse. The author therefore confines himself to points regarding the pulse which illustrate either effects of circulatory derangements or advances in our knowledge from the investigations of recent years. He takes up—

I. Deviations from normal frequency and abnormalities of rhythm.

II. Variations of tension; their causes, consequences, and therapeutic indications; together with the *pulse of heart-disease*.

III. The pulse and cerebral affections.

I. DEVIATIONS FROM NORMAL FREQUENCY.

Increased pressure in the arterial system tends to slow the pulse-rate, and conversely. Yet nervous influence has a far more powerful influence. Almost all departures from the normal state of health are attended by increased pulse-rate. There are, however, cases in which increased frequency of the pulse constitutes itself the disease.

Persistent Frequency of the Pulse.—This condition is due to overstrain of the heart from continuous exertion. It is often called "irritable heart." With the rapid beating of the heart are associated breathlessness, nervousness, faintness, incapacity for exertion, and high arterial tension. The great remedy is rest in bed for one to three weeks. In middle life, a single act of excessive exertion may bring on persistent frequency of the pulse, associated with high tension and perhaps with irregularity.

Paroxysmal Palpitation.—This condition is most commonly a cause of suffering

and danger late in life. It may or may not be associated with heart-disease, and is at any rate rather a complication than a consequence of such disease. The exciting cause—such as indigestion, emotion, the act of taking food, change of position, etc.—acts by producing a sudden relaxation of the arteries, with a consequent diminution of the ordinary resistance, and, as a result, the heart then starts off in violent palpitation.

Another form of palpitation of extraordinary rapidity, and lasting for days or months, is due to some obscure neurotic influence. It may occur at any age, though more common after middle life. There is a tendency to venous stasis. The pulse is vibratory, and gives the impression of but little onward movement of the blood, showing either that the ventricle does not empty itself and is dilated, or that it remains dilated and does not fill in diastole. The latter is more probable, since the cardiac impulse is often very powerful. Sooner or later sudden death is the result. The author reports several very interesting cases.

Infrequent Pulse.—Pressure on the abdominal aorta or large arteries, renal disease with high arterial tension, jaundice, and some nervous affections have some effect in slowing the pulse, but the reduction is not striking. In some rare instances a real infrequency of the pulse (below forty per minute) is found coincident with perfect and vigorous health.

Very closely associated with the simple infrequent pulse is the *bigeminal pulse*. In this the pulse-waves and heart-beats are in couples: a strong beat being followed by a weaker one. Closely related to this is the condition of *dropped beat*, there being two beats of the heart to one of the pulse. Though so nearly allied, Broadbent has met with but one example, in the absence of valvular disease, in which any transition occurred. When, however, valvular disease, especially mitral stenosis, is present, the bigeminal pulse may be a transitional stage in the return from the dropped-beat condition to a normal action.

Treatment by digitalis in mitral stenosis is peculiarly liable to produce one or the other of these phenomena. Broadbent does not agree with Tripier that epilepsy, in the absence of mitral stenosis, is ever the cause of the dropped beat, but reports cases to prove that an infrequent pulse, with or without abortive beats, may induce epileptic or syncopal attacks by slowing the circulation and producing cerebral anæmia.

The study of the heart-sounds in cases of dropped beat is most interesting, and would sometimes seem to prove that there was an alternating action of the ventricles. It is admitted that this phenomenon never occurs; but it is certain that in the dropped-beat condition the right heart contracts effectually in both beats, while the left heart succeeds in raising the aortic valves in the first beat only. It is evident that this extra action of the right ventricle may be most useful in mitral stenosis.

Intermittent and Irregular Pulse.—Occasional or habitual intermission of the pulse, associated with a hurried and imperfect beat of the heart, is perfectly compatible with health, but may be an indication of fatty degeneration of the heart. Brisk walking up and down in the room will usually remove the intermission in the first case, but make it worse in the second.

Marked irregularity of the pulse is oftenest seen in mitral regurgitation and in dilatation of the ventricles. That mitral insufficiency is the only one of all the valvular lesions in which it occurs is to be explained, the author thinks, on mechanical grounds: namely, by the varying pressure on the left auricle during respiration, combined with the incompetency of the valve. Any affection of the respiratory apparatus, as bronchitis or emphysema, increases the irregularity. Irregularity of pulse dependent on nervous influence is seen in dyspepsia and from the abuse of tobacco, but it may occur habitually without any discoverable cause.

(To be continued.)

TRANSLATIONS.

EXPERIMENTS UPON LOSS OF BODILY WEIGHT.—At a recent meeting of the Paris Biological Society, M. Ch. Richét showed tracings obtained by registering apparatus which show the loss of weight occurring in animals during a given time, independently of the ponderable excretions. M. Constantin Paul at a subsequent meeting described an apparatus which he had employed for weighing human beings at the Hôpital Lariboisière.

This apparatus, which is attached to a large weighing-machine constructed on the Quintenz system and capable of weighing a patient in bed, registers the variations of weight which occur. M. Redier, who superintended the clock-work section at the Paris Exhibition of 1878, constructed a most ingenious apparatus for this purpose. This apparatus is composed of two cylinders which are inserted into each other; one of these is attached to the weighing-machine, the other is attached to the registering apparatus. A double clock-work movement causes the inner cylinder to rise or fall according to the greater or lesser variation of weights placed on the weighing-machine, and maintains the weighing-machine in constant equilibrium.

At the same time the variations of weight are inscribed on paper lined in squares, and a clock-work action makes this paper turn so as to inscribe the movement of these variations and their duration. This apparatus thus registers in a continuous manner the weight of objects placed upon the tray of the weighing-machine. It may be employed for weights of sixty or seventy kilogrammes. The registration of these inscriptions is first made with determined weights or with variable weights. It may thus be determined whether the machine has registered correctly the weight of a burning candle or lamp, of a nosegay as it evaporates from it the water in which it is placed, etc. If a man who is in good health is placed upon the weighing-machine, it will be found that he loses about forty grammes an hour. The loss of weight in a convalescent is inconsiderable. But a patient who has become cachectic through phthisis, diabetes, cancer, organic disease of the heart, etc., loses much more in weight. In the case of a man in good health a remarkable fact has been observed,—viz., that at times he increases slightly in weight. M. Paul concludes that a healthy human being absorbs elements from the atmosphere, such as nitrogen or carbon, which he retains.

Elimination of Carbonic Oxide.—M. Zaleski, of Dorpat, has recently published the result of his researches concerning the elimination of oxide of carbon by animal organism. Oxide of carbon, introduced into the abdominal cavity, has not a sufficiently toxic effect to cause the death of an animal. From the abdomen this oxide is absorbed by the blood, as when this gas is absorbed by direct respiration into the lungs.

When introduced into the abdominal cavity, its presence is detected in the products of respiration; the entire quantity absorbed may not be found, but a large proportion is observed. Blood which is saturated with oxide of carbon, injected into the abdominal cavity, is absorbed in the same way as normal blood.

Oxide of carbon which is contained in injected blood mixes with the blood of the vascular system, but in every case its combination with hæmoglobin cannot be proved. In the case of an injection in the abdominal cavity of blood saturated with oxide of carbon, it is impossible to meet with this oxide in the products of respiration by means of the chloride of palladium test.

Whooping-Cough.—Herff (*Deutsche Med. Zeitung*) found in his own person that there is slight degree of inflammation of the larynx in whooping-cough, and that the special spot of greatest hyperæsthesia was in the interarytenoid region. A Norwegian physician, Mohn, has found fumigations of burning sulphur to be of great service. The paroxysms are controlled by the use of cocaine internally (gr. v to xij daily), and by local applications to the throat, or even to the nasal mucous membrane.—*La France Médicale.*

Compound Wine of Creasote for Pulmonary Disorders.—The following is prescribed for incipient pulmonary tuberculosis where the temperature is not much above normal:

℞ Creasoti, 13 G.;
Tr. gentianæ, 30 G.;
Spt. vini, 250 G.;
Vini Xerici, q. s. ad fiat 1000 G.
M.

Sig.—Two or three tablespoonfuls to be taken during the day.—*Revue Générale de Clinique et de Thérapeutique.*

Local Revulsive Action of Iodine.—If a piece of absorbent cotton wet with tincture of iodine be held in contact with the skin, any desired amount of revulsive effect may be obtained, even to blistering or the formation of an eschar.—*La Normandie Médicale.*

EDITORIAL.

THE DIAGNOSIS AND TREATMENT OF CYSTS OF THE PANCREAS.

IT is scarcely more than half a decade since cysts of the pancreas began to excite the interest and attention of surgeons and gynæcologists. In fact, errors of diagnosis, by which enormous pancreatic cysts were mistaken for cysts of the ovary, first brought the former within the boundaries of surgical diagnosis and treatment. Prior to 1881 pathological anatomy had recorded no such growths. Rokitansky merely mentions cysts of the pancreas; Virchow describes instances in which the tumor had attained the size of the fist; Recklinghausen, Klebs, and Birch-Hirschfeld speak of cysts as large as a child's head. Nor did the clinical diagnosticians mention anywhere the fact that these growths may reach forward so as to constitute tumors of the abdomen recognizable by palpation, and even by inspection,—except Friedreich, who states that the tumor may sometimes be felt through the abdominal walls. It is then scarcely a matter of surprise that the enormous cysts described in the recent literature of the subject have led to errors of diagnosis.

Twelve cases—six occurring in men, six in women—have been recorded: one each by Rokitansky, Thiersch, Bozeman, Kulenkampff, Gussenbauer, Dixon, Riedel, Senn, Billroth, Hahn, Ahlfeld, and Küster. In nine of these the diagnosis was erroneous. The cases of Gussenbauer, Senn, and Küster were correctly diagnosticated before operation, and terminated in complete recovery. The last of these observers* has, as a result of careful study of the collected material, reached some important generalizations which place this subject, hitherto involved in deep obscurity, in a clear light.

Cysts of the pancreas are, as a rule, developed in the body or tail of the organ, very rarely in its head. Hence their influence upon digestion varies widely, and may be very trifling. They are usually single. In one instance only (Dixon) were there two, of which one occupied the head and body of the pancreas, the other the tail. Although cysts of this organ have been regarded as belonging to the group of retention-cysts, it is worthy of remark that in none of these cases has either a calculus or an anatomical lesion capable of mechanically obstructing the outflow of the secretion been discovered. The experimental researches of Senn make it highly probable that after such obstruction, as after ligation, the secreted fluid is absorbed, and that accumulation can result only when certain changes in the parenchyma have taken place. The contents of these enormous cysts are usually admixed with old or recent blood.

Their etiology is not clear. Traumatism, excesses in eating and drinking, inflammation of neighboring organs, and enteric fever have been regarded as causes. Doubtless these agencies all act in the same way in inducing interstitial inflammation or hemorrhage in the substance of the organ, thus leading to local contractions and degeneration. The development of the cysts is sometimes very rapid, more frequently it is slow.

Colic-like pains in the region of the stomach, *neuralgia cœliaca*, are usually present, and often very violent. These pains have been in some of the cases regarded as cardialgia or as hepatic colic. The pain is not only paroxysmal, it was also in certain cases periodical.

Increased flow of saliva, the so-called *salivatio pancreatica*, is neither common nor important. Vomiting, however, may

* Deutsche Medicinische Wochenschrift, 1887, Nos. 10 and 11.

occur, and is probably due to mechanical disturbance of the stomach. Diarrhœa is not frequent; nor are fatty stools (steatorrhœa) the rule,—a fact to be explained by the common situation of the cyst: namely, at the body or tail of the pancreas. A very striking symptom is the rapid emaciation. Küster's case lost over thirty pounds in four months. This symptom is probably due not so much to incomplete assimilation as to some disturbance of the cœliac plexus and solar ganglia, to which must also be ascribed the polyuria occasionally noted.

Whatever the symptom-complex, a diagnosis becomes possible only when the cyst has attained such dimensions as enable it to be recognized as a fluctuating tumor by the methods of physical diagnosis. Even when the tumor can be distinctly felt and seen in the epigastrium, the danger of mistaking it in either sex for other form of growth is exceeding great: in man for echinococcus of the liver, spleen, or mesentery, for a distended gall-bladder, or for aneurism of the aorta or its branches; in woman for any one of these, or for cystic disease of the pelvic organs, especially the ovary. Errors of this kind are the most likely when the tumor becomes large enough to reach into and distend all regions of the abdominal cavity. The rarity of cysts of the pancreas as compared with cysts of the ovary, the fact that the growth was first observed in the upper part of the abdomen, the results of bimanual examination in the female as determining the relations of the pelvic organs with the cyst, are important. Percussion affords very positive results. The distention of the stomach, for diagnostic purposes, with carbon dioxide causes it to pass with an increasing area of tympany in front of a pancreatic cyst, and without widening resonance behind an ovarian cyst. Fluid obtained by means of exploratory puncture with a hypodermic syringe is of diagnostic value. The contents of pancreatic cysts—albuminous, usually containing blood and epithelial elements—bear no resemblance to the fluids found in other cysts except in certain forms of ovarian disease. The property of emulsifying fats is not in all cases retained. When present, it is of positive diagnostic significance.

The treatment consists in evacuating the contents of the cyst by means of laparotomy, and stitching the wall of the cyst to that of the abdomen. The resulting fistula has in the three successful cases gradually closed. Total extirpation of the cyst is, in view of the anatomical relations of the parts, an operation of wholly theoretical consideration.

THE TREATMENT OF WHOOPING-COUGH BY ANTIPYRINE.

THE recent report of Dr. Sonnenberger, of Worms, upon "The Pathogenesis and Therapy of Whooping-Cough"* acquires peculiar interest at the present time in view of the wide prevalence hereabout of this disease, much of which is of a degree of severity not common at this season of the year. Its treatment, which must be confessed to rank among the *opprobria* of medicine, is at present far from yielding satisfactory results, notwithstanding the efforts, often heroic, that have been made to conform it to the simplest requirements of the germ-theory of disease. In point of fact, certain of these efforts, such as the use of strong sprays of carbolic acid or other germicide substances, are wholly impracticable, and could not be attempted in private practice. The older modes of treatment, by narcotics, such as belladonna, opium, conium, chloral, etc., while of some value, are inadequate in the graver cases, and not wholly free from danger. Agents directed against the catarrhal symptoms

* Deutsche Medicinische Wochenschrift, No. 14, April 7, 1887.

are for the most part of little effect in any respect, and of none at all in controlling the nervous phenomena. Notwithstanding a list of remedies and plans of treatment of wearisome and discouraging length, there is a manifest disposition on the part of the profession towards pure expectancy in the mild cases and symptom-treating in the severe, that argues poorly for the results of accumulated experience.

Sonnenberg, after using antipyrine in seventy cases in two outbreaks, claims excellent results. Begun in the first stage, its action brought the attacks to a close, with mitigated symptoms,—the paroxysms, as a rule, not exceeding six or seven in twenty-four hours,—in from three to five weeks. When the treatment was not begun till a later period of the attack, the paroxysms were at once influenced for the better, the first sign of improvement being freer expectoration. This was speedily followed by general improvement, and increased ability to retain food. Collapse was in no instance induced. Complications occurred in five of the seventy cases: in two instances pneumonia, in three tuberculosis. Every attention was paid to general hygiene.

What the action of antipyrine may be cannot in the present state of knowledge be positively affirmed. Sonnenberger seems to incline to the view held by Binz and others,—that the effect of the members of the chinolin group within the organism is antiparasitic, as it is outside, and that we thus have an actual specific against whooping-cough in the true sense. To this must be added a very remarkable sedative influence in certain irritable states of the nervous system just beginning to be appreciated as among the properties of this extraordinary group of drugs. At all events, this application of antipyrine invites the fullest clinical investigation, and we shall welcome early and full accounts from those who are in the way of making such researches.

Antipyrine may be given to children in doses of from one-quarter of a grain to three or five grains, according to age; to adults in doses of ten or fifteen grains, three or four times a day. The preferable mode of administration is in the form of powder in sweetened water. It is not disagreeable to take, and in these doses has, as was shown by Petersen, no deleterious effects upon the digestion. It may be continued for several weeks without ill result.

NOTES FROM SPECIAL CORRESPONDENTS.

PARIS.

HYSTERICAL Hemianæsthesia and Toxic Hemianæsthesia was the title of a clinical lecture delivered at the Hospice de la Salpêtrière recently by Professor Charcot. He took advantage of the presence of two patients in the wards to discuss the following questions:

1. Is there a hemianæsthesia coming directly from lead-intoxication?

2. Is there an alcoholic hemianæsthesia which occurs as one of a series of nervous troubles belonging to chronic alcoholism?

He said that "some physicians answer both of these questions in the affirmative, but the study of a large number of cases leads me to think that it is not at all well established that such is the truth; not but what some patients do present themselves in whom saturnism and alcoholism are combined with a unilateral anæsthesia, but I cannot believe that they really form part of the pathology of these chronic forms of intoxication." Passing to the study of the cases, he gave the following history of them: "The first one is that of a man of 27, a house-painter by trade, who came in on the 15th of last June. His mother, he says, is subject to cramps in her legs very violent in character, and coming on every few days; her eyesight is also very bad. This may be tabes. One of his sisters had attacks of convulsive hysteria, in which she cries out, but does not bite her tongue. These symptoms, he tells us, went away after her marriage. The patient himself is a well-formed man; he is not a syphilitic nor an alcoholic subject; he has not had any serious illness, except typhoid fever ten years ago.

"He began working at his trade twelve years ago, and has continued at it ever since, without being troubled with lead-colic or any paralysis of the extensor muscles. Some eighteen months ago, however, he suddenly felt his legs give way beneath him, and something seemed to go upward from his abdomen to his stomach, at the same moment his belly

contracted, and he had a sensation of constriction in the neck. Calling out at this moment, he would have fallen if he had not been held up by one of his fellow-workmen; he remained for half an hour in an insensible state, and on coming to himself his left leg was without feeling in it. He presents, as you see, a high degree of saturnine discoloration of the skin, and the blue line on the gums is well marked; he is also very anæmic.

"For a month these attacks came on daily, the aura starting from the left leg. A treatment with bromides and iodides and sulphur-baths diminished considerably the attacks, but they still recur each fortnight. The left side is weaker than the right, and the left hand trembles most; there is also a left hemianæsthesia. With the right eye he can only distinguish the red colors, and the hearing and taste on the right side are almost abolished. The first idea that strikes you all is that the symptoms are due to attacks of lead-poisoning, but Grissolle showed that the subjects of saturnine epilepsy do not present the same symptoms that this man does. They never make an arc of a circle with their bodies (opisthotonos), nor do they retain a knowledge of the initial symptoms as he does. His face, also, does not take part in the convulsions. Again, when the lead-epileptic gives up his trade the attacks cease, but here after eighteen months they continue in our patient. What is the nature of his attacks, then? Do they depend upon some cerebral lesion? Those among you who have followed our studies regularly will see at once that this is a case of *hysteria only*, as he presents all the symptoms that characterize the hysterical aura: the sensation of constriction in the neck, the noise in the ears, and also that special attitude during the attacks that we call 'arc de cercle,' in which the body rests on the head and heels only. We can also apply an Esmarch's bandage to his arm and produce an artificial contraction of the muscles. It must be admitted now as proved that hysteria exists in man, after all the cases that have been presented; and indeed we can assert without fear of contradiction that it is not at all exceptional in man. I think that possibly saturnism may act a certain *rôle* in producing these nervous troubles in a patient predisposed to them. It certainly brings on attacks of gout as well as other diseases.

"The answer, then, I give to the first question is that a certain number of supposed saturnine hemianæsthesia cases come from hysteria; and that I am inclined to doubt the existence of pure saturnine hemianæsthesia, as I do also that supposed to be caused by alcoholism. The next case is a typical one to decide the last question.

"C., 33 years of age, has been under treatment here for a year past. His father is a violent man, and his mother has attacks in which 'she breaks everything.' A paternal uncle has ataxia, and the patient himself had convulsions as an infant. At seventeen years of age he took to drink, rising at last to as much as five quarts of brandy in a week; this excess was followed by trembling of the hands, nightmare, etc. Two years ago he had his first convulsive attack, in which he fell from his bed, and which was followed by a right hemiplegia. Soon afterwards he had another convulsive attack, when his hemiplegia went away, but was followed by 'mutism.' Since then he has had frequent attacks, and the symptoms commence in an aura that starts from above the right hip. This is followed by constriction of the neck (globus hystericus), tonic convulsions, opisthotonos, and hallucinations. Muscular contractions can be provoked, and right hemianalgesia exists. This is also simply a case of pure hysteria, this time in an alcoholic subject. The nervous predisposition is present in a high degree: violent father, hysterical mother, he himself subject to convulsions as a child, etc. The alcoholism simply brought out the hysteria. The lesson is that this sort of attacks must not be attributed to a *toxic cause only*, and the answer to the two questions given at first is that the affirmative side is not at all proved in either of them."

Action of Rectal Injections of Carbonic Acid on the Respiration.—Professor (Agrégé) Charles Richét (who will most likely take the place of the late Professor Béclard as Professor of Physiology) has been making a series of experiments on this subject. When carbonic acid gas is injected into the rectum and large intestine, whether the person be ill or not, he finds that the pulmonary exhalation will increase immediately after the injection, and it will rise from eight litres per hour (and per kilogramme) to ten litres. The proportion of carbonic acid gas exhaled by the lungs rises also according to the quantity of gas injected into the rectum. It results from these facts that: First, the presence of an excess of carbonic acid gas in the blood determines an excitation of the medulla oblongata, and that this reflex causes an acceleration of the respiratory movements; from which it seems to result that the carbonic acid gas is the true regulator of the act of respiration. Secondly, that this acceleration of respiratory movements brings about an elimination of carbonic acid gas in excess without changing the proportion of oxygen contained in the blood; in a word, without changing or making the slightest modification in the interstitial changes going on in the organism. Professor Brown-Séquard called attention to the fact, however, that there were two series of actions produced, according to the dose used: a small one would excite to action, and a very large one would produce inhibition. M. Richét said this was true, and stated that the elimination of the carbonic acid gas was not primitive, but consecutive to the acceleration of the pulmonary ventilation.

M. Bergeon, of Lyons, is at present in Paris, making some experiments with M. Richét, and he lately presented a phthisical patient to the Anatomical Society who after the treatment had passed a good winter in the cold climate of Geneva, Switzerland. It is, however, stated that when he ceases the injections the dry, crackling râles can be heard at the summit of the lungs. Some favorable cases are seen here of this treatment, and a good report of it has been heard from England, but it is not very much used in the Paris hospitals, and none of the principal professors are using it. The impression got about here, owing to some sensational cable despatches published in local newspapers in regard to this treatment being used in Philadelphia, *that America claimed the invention!* and one of the medical papers takes us severely to task about it. We, however, think that we were one of the first to describe the system as that of M. Bergeon's in our letters, and he got every credit for the invention in a letter published in these columns nearly a year ago.

Development of the Fœtus and Induced Labor in Women having Deformed Pelves.—Dr. Felice La Torre, a distinguished Italian obstetrician, has been making a study of the above question in Paris, and has just published the results in a large and very interesting work, in which he gives the statistics of all the accouchement services here, amounting to thousands of cases. He finds, in regard to the first part of the question, that a narrowed pelvis has no bad influence over the progress and proper development of the product of conception in women who have a deformed brim; the child will be as well formed as in any other normal pelvis. He next examines the effects of intervention in provoked labor before term, and gives the following table:

Before antisepsis was used:

Infants (mortality per 100) .	42.85.
Mothers (mortality per 100) .	26.53.

Since antisepsis has been introduced:

Infants (mortality per 100) .	34.61.
Mothers (mortality per 100) .	00.

In the second part of the work this author studies artificial premature confinement before the introduction of antisepsis and the "couveuse," and since, and he finds both the antiseptic precautions and Tarnier's hatching-cradles* have given splendid results.

He then compares the effects of the Cæsarean operation and early artificial labor, and gives the following results:

Cæsarean Operation.

Mothers cured .	66 6 per cent.
Mothers died .	33.3 per cent.
Infants born alive .	62.4 per cent.
Infants born dead .	37.6 per cent.

Early-provoked Labor.

Mothers cured .	100 per cent.
Mothers died .	00. per cent.
Infants born alive .	88.7 per cent.
Infants died .	11.3 per cent.

He then concludes that the Cæsarean operation, even modified by Saenger, does not give as good results as early-provoked labor, and he thinks that craniotomy is to be preferred to the first when the infant is at term. The following, in brief, are some of La Torre's conclusions. Spontaneous delivery before term is more frequent in well-formed subjects than in those who are afflicted with pelvic deformity. The product of conception acquires the same development as to weight and volume in a deformed pelvis as it does in a well-formed one. There being no normal proportion between the child and the pelvis, it is evident that a fœtus at term cannot pass, without danger, through a pelvis measuring less than nine centimetres: in such cases the infants usually die and the mothers run great risks. To prevent the serious danger to women who have a narrowed pelvis (between five and a half and nine centimetres) we must bring about premature labor before term. With antiseptic precautions all the mothers are saved, and eighty-eight per cent. of the children.

Not only is premature labor advocated by French accoucheurs at present, but even abortion is openly advised when the continuation of the pregnancy will likely be fatal to the mother. Professor Pajot says, "Those who wait until the woman with a narrow pelvis is at full term, in order then to perform a Cæsarean operation or some other one, are like the savages who cut down a beautiful tree to get at the fruit." A writer asks, "Who would dare plunge a craniotome into the brain of a living child?" But what right have we—or, rather, the laparotomist—to take up a knife to risk the life of a woman in good health, who may be the joy of her family, or even its support in old age, simply to most likely exchange her life for the possible life of an infant of whom we know nothing in regard to its form or possible chance of living?

The Bacillus of Typhoid Fever.—Dr. Chantemesse, the head of Professor Cornil's laboratory, has been making some interesting experiments on this bacillus and the etiology of typhoid fever, with M. Vidal. He indicates a method for finding this micro-organism. It consists in simply adding to each of the gelatin tubes used (containing ten centigrammes each) four or five drops of a ten-per-cent. solu-

* See Clinical Lecture, page 653, *ante*.

tion of carbolic acid; this is afterwards used for the isolating-plates. The first tube is inoculated by passing a platinum wire through it that has first been steeped in the typhoid dejections; the addition of this feeble quantity of carbolic acid prevents the formation of other micro-organisms that otherwise would rapidly liquefy the gelatin. Many of these are much the same form as Eberth's bacillus, some of which can usually be found in the human mouth, but they can be distinguished by the fact that the typhoid bacillus is mobile, while the others are not. It seems that the real typhoid microbe lives for a long time in fecal matter, and no doubt is the active agent in causing the fever to be spread abroad. Passing on to the study of antiseptic agents on these matters, the authors find that only sulphuric acid in five-per-cent. solution, and carbolic acid in five- and ten-per-cent. solutions, have an action, and they *only when contact has been prolonged for some time*. Among the internal remedies employed, such as thalline, antipyrine, kairine, quinine, etc., they find that the one that acts best is sulphate of quinine, which, in a solution of one to eight hundred, usually stops the development of the typhoid bacillus.

In a further series of experiments M. Chantemesse shows that the opinion of Arnould, that water even rich in organic matters was antipathic to the inferior pathological micro-organisms, is not true. Taking a large bottle containing a little sand and full of water, which had been sterilized, some of the typhoid bacilli were put into it, and during the first few weeks the top of the water was found to give a culture of the bacillus. But after standing two months the surface-water did not contain any more of the microbes; on then decanting the water, and adding a little fresh water from the spigot, the earth and sand left in the bottle were enough to reproduce the bacilli in great quantities. This experiment shows how it is, after drawing off the water from a reservoir to clean it and then refilling it, that typhoid will break out in people using the fresh supply if it contain the bacillus. Numbers of such instances are known. When the water has settled, its superior layers seem to be inoffensive; but if the bottom is stirred up, the germs rise up and produce the disease. It is rather lucky that water must be rather warm to keep up the virulence of these bacilli (at least 19° C.); as a rule, our drinking-water does not reach that temperature, except in small reservoirs and in extremely hot weather; and this is given as a reason why typhoid epidemics are more frequent in summer and in hot climates. It might be presented as an excuse for Americans drinking ice-water that it is sterilized, if the ice was only pure. In any case, these studies are to be recommended to doctors not so much for the typhoid patients they may have to treat, but that they can fill the *rôle* of a true physician, which is not so much to cure, which is difficult, but to prevent, which is often easy.

Arthritic Diabetes.—Dr. Blanquinque says that this form of disease is the most common, as it occurs in ninety per cent. of diabetics. The patients are mostly fat people from forty to sixty years old, often gouty, and good livers, while taking but little exercise. The proportion of sugar in the urine will vary, of course, but the following mode of treatment has made it fall in two weeks and often caused it to disappear in a month. In the first place, give the following prescription:

℞ Extract. valerianæ, 0.20 centigramme;
Extract. opii, 0.015 milligramme;
Sodii arseniatis, 0.002 milligramme. M.
Fiat pil. no. i.

Give from four to six such pills with the principal meals of the day. The effect will be to calm the cough and to diminish the desire to urinate, as well as to act upon the disease. When the thirst is intense, the dose of opium in the pill should be increased at night. In the second place, the alimentary régime has considerable importance, no matter what has been said against it. Bouchardat's method is the best known, so it will not be necessary to enlarge upon it, except to say that it may be slightly modified so as to permit the use of bread if only the crust part is used, and he prefers that it should be toasted. Potatoes are also allowed now, if they are fried. All pastry, fruits, etc., are forbidden of course. As to the drink: wine is allowed of the red Bordeaux kinds, if it is mixed with Vichy water; coffee or tea is allowed after dinner with cognac, and if sweetening be required a little glycerin is permitted. Vichy water is to be drunk morning and evening, and a season passed at Vichy is recommended to those who can go. Bouchardat used to insist on his clients cutting their own wood, and practising fencing and other gymnastic exercises; and Chomel said "they should digest with their legs." Certainly we burn our sugar and fat by muscular contraction, so that exercise and frictions of all kinds, such as massage, are indicated.

Dr. Martineau's recommendation of lithia and arsenic has caused a good deal of comment and trial; but as it is not always convenient to make the water he uses, the following pill-form which M. Vigier gives may be used instead in the arthritic forms of this disease:

℞ Lithii carbonat., 0.10 centigramme;
Sodii arseniat., 0.003 milligramme;
Extract. gentianæ, 0.05 centigramme.
M. Fiat pilulæ.
S.—Give one of these pills evening and morning for several months.

Considerable comment has been made here on a phrase in a letter that Billroth, of Vienna, has written in one of the newspapers there.

Speaking of Pasteur's work, he said, "Well, we don't blame the French for applauding so much Pasteur's discovery, for not only have they not made any great progress in science these last twenty years, but they are following with difficulty and halting steps the colossal progress of German and English science." To put it mildly, this way of talking by the great Vienna surgeon has caused a great deal of irritation in Paris, and Herr Billroth is curtly reminded that he and others are much indebted for their education to such men as the illustrious dead French surgeons were, not to mention the ones now living. They also ask him what sort of men in neuropathology Germany can present in the last twenty years to compare with Duchenne (of Boulogne), Vulpian, Charcot, etc., or in physiology with Magendie, Flourens, Longet, Bernard, P. Bert, Brown-Séquard, etc. But, as that great lady, Mrs. Partington, once said, "comparisons are odorous," and, if the newspaper account can be relied upon, we can only wonder that a man of Billroth's stamp could be guilty of making them.

THOMAS LINN, M.D.

PARIS, June 3, 1887.

PROCEEDINGS OF SOCIETIES.

AMERICAN MEDICAL ASSOCIATION.

(Continued from page 640.)

Second Day, General Session.

ON motion, the regular order was suspended to receive reports of committees.

The Committee of Arrangements reported a number of invitations to the members, which were accepted.

THE REPORT OF THE TRUSTEES OF THE JOURNAL

was read by Dr. J. M. Toner. Dr. N. S. Davis, by special request of the Trustees, had been induced to continue in charge of editorial and publishing departments. The establishment of a printing-office by the Journal had worked satisfactorily. The report of the Editor shows an increase of circulation and an increased income. Total cost of the Journal of the Association, for the year ending March 31, 1887, was $15,920.96; the total receipts from all sources were $21,723.22,—from the Journal alone, $7580 63; value of property on hand, $1058.56. The Editor said, "When the Journal was commenced in 1883, the New York State Medical Society had recently repudiated the National Code of Ethics, thereby forfeiting her right to membership in the American Medical Association, and the seditious doctrine of a New Code or No Code was being actively disseminated in other States, and the Association was being misrepresented and denounced by some of the most influential medical journals in the country. The result of this Code controversy was the final withdrawal from membership of a large number of those who espoused the New York Code during the years 1883–84. Hardly had this Code revolt spent its force, when a still more bitter opposition was encountered by the Association in attempting to effect a preliminary organization for the Ninth International Medical Congress,—an opposition which did not yield until after the annual meeting of the Association in May last, and many of those engaged in it had withdrawn either by direct request or by refusal to pay their dues. The full force of this last revolt was fairly spent during the first half of the Journal year, and during the last six months there have been more applications for membership and renewals of subscriptions than at any previous time since the Journal was established. The fact that in less than four years of such unprecedented professional controversy the Journal should have been sustained, while steadily, firmly, though temperately defending the Association, its National Code of Ethics, and persistently advocating the only practicable representative organization of the whole profession by local, State, and national Associations, and more than double its circulation, and at the same time increase the income of the Association more than threefold, certainly demonstrates the wisdom of its establishment, if it does not prove the ability, efficiency, and prudence of those having the responsibility of its management." In conclusion, the Editor recommended the addition of four pages of reading-matter to each number of the Journal at the commencement of the next volume. The Trustees had been authorized to expend $6000 for editorial work, but had limited it to $2758.95 during the past year in order to keep out of debt.

On motion of Dr. William Brodie, the report was adopted, with applause.

The special committee appointed at the last meeting to consider

PROPOSED CHANGES IN THE PLAN OF ORGANIZATION AND BY-LAWS OF THE ASSOCIATION

reported through the chairman, Dr. N. S. Davis. The plan of organization of the British Medical Association was first critically examined, and found not suited to the profession of the United States, which is spread over such a large area of country. The present plan of State and County Medical Societies sending delegates to the national Association was considered better suited to the organization of the whole profession. The following changes were proposed:

"*Members by Application* shall consist of such members of State, County, and District Medical Societies entitled to representation in this Association as shall make application in writing to the Treasurer, and accompany said

application with a certificate of good standing signed by the President and Secretary of the Society of which they are members, and the amount of the annual membership fee (five dollars). They shall have their name on the roll, and have all the rights and privileges accorded to Permanent Members, and shall retain their membership on the same terms."

This enables any one or even all of the members of recognized State and local Societies, under adequate safeguards, to become *de facto* permanent members of the American Medical Association without the expense of attending an annual meeting.

In place of the present Nominating Committee it is recommended to create a General Committee or Council, composed of two members from each State or other organization entitled to representation, each to serve for two years. It shall meet annually at the place and on the day preceding each annual meeting of the Association, and as often in that week as may be necessary: to nominate on the third day of each annual meeting all the general officers of the Association (none of whom shall be members of its own body), the members of the Committee on Arrangements, the Committee on Necrology, seven members of the Judicial Council, and three members of the Board of Trustees for Publication, for election by the Association; to recommend the place and time for holding the next annual meeting; and to consider and report on all subjects that may be referred to it by vote of the Association. The paragraph relating to the Committee on Publication should be rescinded, since its duties are performed by the Board of Trustees of the Journal, whose duties are to be specifically detailed and enlarged by another amendment.

The by-law requiring chairmen of Sections to read addresses before the general session to be changed to make it read "before the Section over which they preside." It was also recommended that the Standing Committee be empowered to invite three members of the Association, eminent in some of its departments, to deliver addresses in the general sessions of the next ensuing annual meeting, —one on a medical subject, another on a surgical, and a third upon state medicine. Both of these are in accordance with the practice of the British Medical Association.

On motion of Dr. Early, of Pennsylvania, the report was adopted and the committee discharged.

A communication was received from the American Pharmaceutical Association, asking the aid and co-operation of the American Medical Association in promoting the prescribing by physicians of officinal medicines only, or such preparations as have published formulas, in preference to others.

On motion, the communication was received and adopted as a resolution.

Dr. J. L. Lynch, of Baltimore, then read the

ADDRESS IN MEDICINE.

The first subject discussed was that of antipyretics. He attributed to fever a fatal influence in most of the diseases in which it is present, and considered that the means for safely reducing and keeping down a tendency to morbidly high temperature unquestionably constitute the most powerful weapon we possess in combating a large majority of the diseases to which mankind is heir. Medicines which increase heat-loss, apyretics, are less valuable than those which prevent the abnormal heat-development. Quinine was the only agent of this kind that was in our possession until lately, when antipyrine was introduced by Knorr, of Erlangen. In gramme doses, repeated every hour until three or four doses have been taken, and afterwards every three or four hours, it had proved very efficient in his hands for reducing hyperpyrexia. Antifebrine (acetanilide) may be substituted, as it is cheaper, but it is not soluble in water, while antipyrine is. The new cardiac stimulants strophanthin and spartein sulphate were pronounced less useful than digitalis. The remaining portion of the address was devoted to a consideration of phthisis. He denied that the bacillus is the sole or even a frequent etiological factor in initiating tuberculosis, but did not deny that it has some pathological significance. Hygienic measures are of primary importance in preventing or curing phthisis. Bergeon's method, which he pronounced a mistaken one, is based upon an incorrect theory of the disease.

Third Day, General Session.

The President announced that the adoption of the report of the special committee on Changes of Organization also carried with it the adoption of the recommendations except those which were amendments to the Constitution, which must lie over until the next meeting under the rule.

A congratulatory telegram was received from the Ontario Medical Association in session, and Dr. William Brodie directed to send one in response.

OFFICERS FOR THE ENSUING YEAR.

President.—Dr. A. Y. P. Garnett, District of Columbia.

Vice-Presidents.—Drs. Duncan Eve, Tennessee; Darwin Colvin, New York; Charles J. O'Hagan, North Carolina; A. Stedman, Colorado.

Librarian.—Dr. C. H. A. Kleinschmidt, District of Columbia.

Treasurer.—Dr. R. J. Dunglison, Pennsylvania.

Assistant-Secretary.—Dr. Joseph Ransohoff, Ohio.

The place for next meeting is Cincinnati, on the second Tuesday in May, 1888. Chairman of Committee of Arrangements, with

power to appoint members of Committee, W. W. Dawson, of Cincinnati.

Trustees of the Journal.—Drs. L. Connor, Michigan; E. O. Shakespeare, Pennsylvania; W. T. Briggs, Tennessee.

Judicial Council.—Drs. J. H. Murphy, Minnesota; Joseph M. Toner, District of Columbia; J. K. Bartlett, Wisconsin; A. B. Sloan, Missouri; X. C. Scott, Ohio; B. McClure, Iowa; D. W. Stormont, Kansas. To fill a vacancy, James F. Hibberd, Indiana.

Committee on State Medicine.—Alabama, Jerome Cochrane; Arkansas, R. G. Jennings; California, J. W. Robertson; Colorado, P. Brumund; Connecticut, W. H. Whittimore; District of Columbia, G. W. Cook; Florida, N. D. Phillips; Georgia, T. S. Hopkins; Illinois, E. P. Cook; Indiana, J. M. Beard; Iowa, G. F. Jenkins; Kansas, W. L. Schenck; Kentucky, J. A. Larrabee; Louisiana, T. G. Richardson; Maine, Thomas Foster; Maryland, G. H. Rohé; Massachusetts, Grace Wolcott; Michigan, A. W. Alvord; Minnesota, C. N. Hewitt; Mississippi, T. R. Trotter; Missouri, Lester Hall; Nebraska, William Knapp; North Carolina, Eugene Grissom; New Hampshire, W. P. Porter; New Jersey, B. A. Watson; New York, A. N. Bell; Ohio, F. C. Bain; Pennsylvania, J. C. Dunn; Rhode Island, W. J. Burge; South Carolina, T. Legate; Tennessee, R. Cheatham; Texas, J. E. Sears; Vermont, S. H. Griswold; Virginia, H. M. Nash; West Virginia, J. E. Reeve; Wisconsin, J. K. Bartlett; United States Navy, Delavan Bloodgood; United States Marine Hospital, C. P. Goldsborough; Dakota Territory, E. M. Dow; New Mexico, R. Bailey.

Committee on Necrology.—J. M. Toner, Washington, D.C., Chairman; T. E. Murrell, Arkansas; B. B. Wyman, Alabama; J. G. Terry, California; M. H. Sears, Colorado; R. A. Lancaster, Florida; E. Ingalls, Illinois; J. F. Hibbard, Indiana; J. M. Emmert, Iowa; L. M. Minney, Kansas; J. G. Brooks, Kentucky; R. Matas, Louisiana; John Morris, Maryland: E. C. Bell, Massachusetts; G. E. Ramsey, Michigan; A. W. Strickfield, Minnesota; H. B. Merrill, Missouri; A. S. von Mansfelde, Nebraska; J. H. Tucker, North Carolina; J. F. Ill, New Jersey; J. W. Parsons, New Hampshire; L. D. Trowbridge, New York; H. J. Herrick, Ohio; F. Woodbury, Pennsylvania; W. J. Burge, Rhode Island; F. L. Parker, South Carolina; J. M. Savage, Tennessee; R. W. Park, Texas; M. R. Crane, Vermont; L. Ashton, Virginia; J. T. Reeve, Wisconsin; J. N. Weir, Dakota; R. Bailey, New Mexico.

On motion of Dr. P. H. Millard, the report was accepted.

The Permanent Secretary announced the officers of the Sections, as follows:

Practice of Medicine, Materia Medica, and Physiology.—Chairman, A. B. Palmer, Michigan; Secretary, N. S. Davis, Jr., Illinois.

Section on Obstetrics and Diseases of Women.—Chairman, Eli Van de Warker, New York; Secretary, E. W. Cushing, Massachusetts.

Section on Surgery and Anatomy.—Chairman, Donald McLean, Michigan; Secretary, B. A. Watson, New Jersey.

Section on Ophthalmology and Otology.—Chairman, F. E. Hotz, Illinois; Secretary, H. H. Jackson, Pennsylvania.

Diseases of Children.—Chairman, F. E. Waxham, Illinois; Secretary, W. B. Lawrence, Arkansas.

Oral and Dental Surgery.—Chairman, J. Taft, Ohio; Secretary, E. S. Talbot, Illinois.

State Medicine.—Chairman, H. B. Baker, Michigan; Secretary, S. T. Armstrong, Tennessee.

Medical Jurisprudence.—Chairman, E. M. Reid, Maryland; Secretary, C. B. Bell, Massachusetts.

Section on Dermatology and Syphilography.—Chairman, L. D. Bulkley, New York; Secretary, T. F. Dunlap, Kentucky.

Dr. N. S. Davis, Sr., having mentioned the necessity of appointing members to prepare the three addresses in accordance with the amendments which had been adopted, after some discussion Dr. D. J. Roberts, of Tennessee, moved that action on this point be deferred until 1888. Dr. Davis moved as an amendment that the action as to the By-Laws be permitted to remain, inasmuch as there were very few negative votes, but that the others, which were amendments to the Constitution, should lie over for ratification at the next meeting. This was accepted by the mover, and was unanimously adopted.

Dr. G. H. Rohé, Secretary of the Rush Monument Committee, read the report of the Committee, showing that the total contribution to the fund is three hundred and eighty-nine dollars. The Treasurer's account was audited and found correct.

CREMATION.

Dr. John Morris, of Baltimore, read for Dr. J. M. Keller, of Arkansas, Chairman, the report of the special committee appointed at the last meeting to report on this subject. In default of cremation, and to prepare the public mind for it, cremacausis, or rapid disintegration of the body by caustic agents, was advised. The following resolution was appended to the report:

"*Resolved*, That it is the judgment of the American Medical Association that the burial of all persons dying with zymotic diseases should be placed by law under the control of the health authorities, and that in all such cases of disease chemical agents should be used by such authorities to bring about a rapid disintegration of the dead body."

At the request of the Committee, the report was referred to the Section on State Medicine for action.

INOCULATION FOR YELLOW FEVER.

A report from the special committee on Yellow-Fever Inoculation, through Dr. J. McF. Gaston, of Georgia, was read, recommending the passage of the following resolutions:

"*Whereas*, An appropriation has been made by Congress for investigating yellow-fever inoculation, and an eminent bacteriologist has been appointed to examine the data presented in Mexico and Brazil;

"*Resolved*, That it is desirable that two other members of the medical profession should be associated in this work, one having practical and clinical acquaintance with yellow fever, and the other being able to communicate with the population of the respective localities.

"*Resolved*, That a committee of three be appointed by the President of this Association to communicate this action to President Cleveland, setting forth the grounds for such recommendation."

Dr. G. H. Rohé unsuccessfully moved to table the resolution; it was adopted. The regular order of business was resumed.

The Address in Obstetrics was read by Dr. F. M. Johnson, of Missouri, Chairman of this Section.

Dr. George H. Rohé, Chairman, read the

ADDRESS IN STATE MEDICINE.

After referring to the bacterial character of several diseases, he showed the importance of sanitary measures. In typhoid the physician fails in his duty who does not adopt every means for the disinfection of the intestinal discharges. Health authorities should have under their control establishments where disinfection can be carried out on a large scale and at the public expense. Such institutions are in successful operation in a number of Continental European cities.

"Quarantine, a word which for more than five centuries has been synonymous with barbarism, is becoming under modern methods a safeguard to the public against infection and an advantage instead of obstruction to commerce. The results achieved at the model quarantine station at New Orleans encourage the hope, and almost warrant the prediction, that the days of the quarantines of detention, whether by sea or land, are past, and that quarantine in future will mean simply *thorough disinfection* of fomites, and of course effective isolation of persons already infected.

"Cremation of garbage seems to be the best method yet devised for the inoffensive destruction or final disposal of solid city wastes.

"The irrigation system of sewage-disposal has steadily won favor. In Berlin, Breslau, and Dantzic in Germany, Birmingham in England, and Pullman and other places in this country, it has been in successful operation. Chemical precipitation and purification of sewage has also been adopted, with satisfactory results, in various German cities. A board of distinguished engineers recently recommended the same system for the city of Providence, Rhode Island.

"Professor Vaughan's discovery of a very poisonous ptomaine in cheese, ice-cream, and milk undergoing certain chemical changes has been confirmed by a number of investigators in various parts of the country. Vaughan's suggestion that tyrotoxicon may be found to be the poison which produces cholera infantum opens up a new field for investigation in which every physician must of necessity be interested.

"Analyses of food and drugs made during the year in Massachusetts and New York show the wide extent to which adulteration is practised and how the people are defrauded. Among the most startling instances are olive oil, of which sixty-eight samples out of ninety-one were spurious. Vinegar was adulterated in seventy-nine samples out of one hundred and sixteen, mustard one hundred and twenty-four times in two hundred and eleven, white pepper sixty-three times in one hundred and twenty-eight, black pepper forty-one times in seventy-one, mace twenty-nine times in forty-five. Of nine samples of horseradish examined only one was found genuine. A precipitate of uncrystallizable sugar and coloring-matter and chloride of tin (poisonous) is sold to candy-makers for making confectionery. Citrate of iron from respectable manufacturers contained three and a half per cent. of quinine, instead of the twelve per cent. demanded by the pharmacopœia. Authority and means should be given to the health-authorities to protect the public from these frauds, many of which are a source of danger to life and health.

"Statistics collected by the speaker show that five-sixths of the inhabitants of cities in this country have no facilities for bathing, except such as are afforded by a pail and sponge, or an easily accessible river, lake, or other body of water. The establishment of public baths is urgently recommended, both as a sanitary as well as a normal measure. Tub or pool baths are objectionable both on account of expense and lack of privacy in the latter. The spray-baths in use in the German and French army barracks are recommended. These are not expensive, either in first cost or administration, and allow each bather absolute privacy and the opportunity for a thorough cleansing in clean water. Public baths should be open the year round, and not only during the summer.

"A number of instances are grouped together showing how the enforcement of appropriate sanitary measures has saved life. In Michigan the saving of life from one disease (scarlet fever) has amounted during the last eleven years to three thousand seven hundred and eighteen, or three hundred and thirty-eight per year. In 1886 appropriate sanitary measures saved the lives of two hundred and

ninety-eight persons, who would have died of diphtheria if such measures had not been enforced. In England and Wales the average annual saving of life due to sanitary measures has amounted, in the five years ending 1885, to sixty-two thousand. In Baltimore a marked reduction of deaths from infectious diseases has followed the enforcement of certain sanitary precautions. In Memphis the death-rate has been reduced in six years from thirty-five per thousand to 23.80 per thousand. In Chicago the reduction of mortality in the last five years has been from 25.69 per thousand to 19.46 per thousand, a net saving of seventeen thousand two hundred and fourteen lives in that city during that period.

"While all advances in sanitary administration have doubtless contributed to produce these good results, the main influence is to be attributed to three factors. These are *compulsory notification of infectious diseases, prompt and effective isolation of the sick and infected, and thorough disinfection of all infected articles and sources of infection.* These must be the watchwords of the practical sanitarian of the future."

Dr. R. J. Dunglison, Treasurer of the Association, presented his report for the past year. Balance on hand, $1403.77. The accounts were audited and found correct.

On motion of Dr. N. S. Davis, one thousand —amended from five hundred—dollars was ordered to be appropriated for the International Medical Congress.

The report of the Librarian, Dr. C. H. Kleinschmidt, of Washington, D.C., was read and approved. Subscription to the *Index Medicus* was ordered to be renewed.

Fourth Day.

The Nominating Committee reported the following names of physicians to deliver addresses at the next meeting: R. Beverly Cole, M.D., of San Francisco, California, on General Medicine; E. M. Moore, M.D., of Rochester, New York, on Surgery; James L. Cabell, M.D., of Virginia, on Public Medicine.

The Association adopted the report of the Committee, and Drs. Toner, Griscom, and Darwin Colvin were appointed a committee to notify those selected to deliver addresses, with power to fill vacancies.

The following was offered by Surgeon-General Hamilton, of the United States Marine Hospital Service:

"*Whereas*, The President of the United States has appointed George M. Sternberg, Surgeon United States Army, to proceed to Mexico and Brazil for the purpose of investigating the method there practised for the prevention of yellow fever by inoculation;

"*Whereas*, This report will be accompanied by photo-micrographic illustrations of the appearance of the principal organs of the body affected by yellow fever: therefore, be it

"*Resolved*, That the Senate and House of Representatives be requested to cause such number of copies of Dr. Sternberg's report to be printed as may be needed by the profession of medicine of the United States; and be it further

"*Resolved*, That the resolution on this subject passed yesterday be rescinded."

Dr. J. McF. Gaston objected that it was not in order. After some discussion, the previous question was demanded by the proper number. It was decided in the affirmative by a large vote, and the resolution of Dr. Hamilton was then adopted.

The Address in Dental and Oral Surgery was read by Dr. J. S. Marshall, of Illinois, Chairman of the Section. He advocated preservative treatment of teeth, and suggested that instruction should regularly be given on the subject in medical colleges.

The Address in Medical Jurisprudence was read by Dr. I. N. Quimby, Chairman of the Section. After he had discussed the subject historically, he took up for especial condemnation the crimes of fœticide and intoxication.

On motion of Dr. A. N. Bell, it was agreed that the committees should be appointed as requested in this Address.

The President appointed them as follows:

Criminality of Fœticide, and Measures for its Prevention.—I. N. Quimby, New Jersey; W. B. Atkinson, Pennsylvania; W. H. Byford, Illinois.

Duties Commonly Exercised by Coroners.—H. O. Marcy, Massachusetts; J. H. H. Burge, New York; W. W. Dawson, Ohio.

Dr. J. M. Toner reported that the necrological notices had been published as before.

The report of the Auditors was presented and accepted:

"The undersigned, Auditing Committee of the accounts of the Treasurer of the American Medical Association, and also of the Treasurer of the Board of Trustees, report that they have carefully examined the accounts of said officers, and find them correctly cast and properly vouched, and that the balances are as reported by said officers to the Association. In behalf of the Auditing Committee, ALONZO GARCELON,

"*Chairman.*"

Dr. Davis, of the Committee on Meteorological Investigations, etc., reported progress. On motion of Dr. Brodie, the report was accepted and the Committee continued.

Dr. Davis offered the following:

"*Resolved*, That the regular graduates of such dental and oral schools and colleges as require of their students a standard of preliminary or general education and a term of professional study equal to the best class of the medical colleges of this country, and embrace in their curriculum all the fundamental branches of medicine, differing chiefly by substituting practical and clinical instruction

in dental and oral medicine and surgery in place of practical and clinical instruction in general medicine and surgery, be recognized as members of the regular profession of medicine, and eligible to membership in this Association on the same conditions and subject to the same regulations as other members."

This was adopted by a large majority.

Dr. N. S. Davis read the following:

"*Resolved*, That the Committee of Arrangements are hereby directed at each annual meeting of the Association to so arrange the programmes regarding entertainments and receptions that the evening of the third day be reserved for a regular annual dinner under the following general regulations. The chief registration-officer shall provide for each registration-table a paper headed 'Annual Dinner of the American Medical Association,' with two columns for names, one headed tickets without wines or liquors, at a specified sum; the other tickets with wines, etc., at a specified sum; that each member, when registering, can have the opportunity to take a ticket for the dinner if he desires it, and can be entirely free to enjoy the dinner not only without using wines, but also without being required to assist in paying for that drunk by others; while those who desire the addition of wines will enjoy the same liberty. It shall be the duty of the Committee of Arrangements to select a proper place for the dinner, to ascertain the cost per plate on the plan already indicated, that the price paid for the tickets will pay the entire cost of the dinner, leaving no part to be paid either by the local profession or by the Treasurer of the Association."

This was also adopted by a large majority.

A motion to give an honorarium to the Permanent Secretary was lost, as all the income would be needed for the Journal.

On motion of Dr. E. A. Wood, of Pennsylvania, the President was requested to appoint a committee of three to prepare a report on Dietetics to be read at the next meeting. This was carried, and the President appointed Drs. E. A. Wood, J. S. Whittaker, and Frank Woodbury.

The Secretary announced the receipt of a telegram from the President-elect, A. Y. P. Garnett, M.D., of Washington, D.C., acknowledging the honor which had been conferred upon him, with regret at being unable to attend in person.

The usual vote of thanks was prepared and read by Dr. William Brodie, and unanimously adopted.

The retiring President, Dr. Gregory, in a brief address thanked the members for their assistance in conducting this very successful meeting, and declared that in discharging his duties as President he had achieved his highest ambition in life.

The session was then declared adjourned.

An excursion to Pullman was provided for a number of the members in the afternoon.

THE AMERICAN LARYNGOLOGICAL ASSOCIATION.

MEETING OF MAY 26, 27, and 28, 1887.

(Continued from page 642.)

Second Day.

FURTHER RESEARCHES UPON THE FUNCTION OF THE RECURRENT LARYNGEAL NERVE: BEING A SERIES OF EXPERIMENTS FROM THE BIOLOGICAL LABORATORY OF THE JOHNS HOPKINS UNIVERSITY. BY DR. FRANK DONALDSON, JR., OF BALTIMORE.

IN a former paper read at a previous meeting the author had criticised certain conclusions advanced by Dr. F. H. Hooper. The conclusions which Dr. Donaldson had reached were: that the constrictors do not cease to act under deep narcosis or suspension of consciousness from any cause; that we do not always obtain abduction on irritation when consciousness is suspended; that the abduction was not reflex, and was not dependent on unconsciousness; that it is with weak stimuli that abduction takes place, and the movement passes into adduction as the stimulus is increased (these results invariably followed whether the animal was slightly or deeply narcotized, or when the medulla was destroyed, or when local death had taken place); that after strong and continued stimuli the abductor muscles became worn out and did not respond to stimuli.

These conclusions had been strongly criticised, and the present series of experiments were performed to test the correctness of the above views. He had shown that abduction of the vocal bands can be obtained without ether, and that it is a physiological fact that opening or closing of the larynx depends upon the strength of the stimulus. With weak stimuli abduction was produced, while with strong stimuli adduction was caused.

THE ANATOMY AND PHYSIOLOGY OF THE RECURRENT LARYNGEAL NERVE; FROM THE PHYSIOLOGICAL LABORATORY OF HARVARD MEDICAL SCHOOL. BY FRANKLIN H. HOOPER, M.D., OF BOSTON.

The anatomy of this nerve is now complete and exact; but up to a very recent date much confusion existed on this subject. To find out why these nerves were recurrent it is necessary to begin with the embryo. The recurrence is due to certain changes in the branchial arches and the descent of the heart into the thorax. At one time in the period of development these laryngeal nerves are straight, but as the heart descends they are brought down. The proof of this is found in the abnormal condition of the nerve in cases of irregularity of the great vessels which branch from the aorta. These nerves (at least in dogs and cats) contain no sensory fibres.

The larynx possesses three functions, controlled by three distinct sets of muscles, all

innervated by the recurrent nerves. These functions are: 1, respiration; 2, sphincter action, which closes the larynx and prevents the entrance of foreign bodies, and plays an important part in expulsive acts; and, 3, phonatory action.

Stimuli applied to recurrent nerves produces adduction in certain animals (dogs), and abduction in other animals (cats). Only a few experiments have been made in man, but as far as they go they seem to show that stimulation closes the glottis. Under ether or profound morphia-narcosis, stimulation of the recurrent nerves produces opening of the glottis in dogs. Three hundred and twelve experiments were reported. Some of the animals were under the influence of chloral, chloroform, morphia, or ether. Under ether dilatation was produced with weak currents, while contraction could not be produced with even the strongest current. As the dog begins to come out of the ether, dilatation cannot be induced with any current, while contraction is brought about by currents decreasing in intensity as the effect of the ether passes off. A similar effect was observed in one case after the use of a large dose of morphia. After small doses of ether, stimulation produces two effects: first vibration, second closure. Under large doses of ether, four effects are observed, according to the intensity of the irritation: vibration, complete dilatation, mixed movement, and closure. After small doses of morphine, chloral, and chloroform, stimulation produces the same effects as after small doses of ether.

DISCUSSION.

In the discussion Dr. Knight cautioned the Congress with regard to rashly applying the results of experiments upon animals to the human subject. The effects vary greatly under circumstances which are not well understood.

Dr. Allen M. Starr, of New York, recently had had an opportunity to see in Paris some experiments by Charcot on hypnotized individuals. It is well known that in this state slight percussion of a nerve will produce contraction in the muscles supplied by that nerve. In one of these cases slight stroking in the course of the recurrent laryngeal nerve over the trachea, below the larynx, produced such adduction of the vocal cords and so interfered with breathing that it became a question whether it would not be necessary to resort to tracheotomy.

Dr. F. H. Hooper said that he had been unable to get the effect which Dr. Donaldson had described.

CERTAIN MEASURES FOR THE RELIEF OF CONGESTIVE HEADACHES. BY WILLIAM C. GLASGOW, M.D., OF ST. LOUIS.

The most severe symptoms in this condition are the pain and sense of constriction of the forehead. If the pain be analyzed, it will be found that it is of two kinds: one gives a dull sense of fulness and occasional throbbing over the temple; the other is of the sharp, lancinating character so generally known as neuralgia. At times both of these varieties are present in the same case. In the one there is fulness of the vessels, and in the other disordered nerve-action. Both varieties are often due to the same pathological condition of the nasal chambers. During congestive headache, if we examine the nose we find the cavernous bodies are full and tense; the degree of tenseness corresponds to a certain extent to the degree of headache. The method of treatment which he had adopted during the past four years had been the local abstraction of blood. A knife is not required; a simple prick of the mucous membrane is sufficient. In many cases the relief is immediate. The operation may have to be repeated in a month or two. He had seen few cases in which permanent relief had not followed a repetition of the operation from two to six times. The amount of blood drawn rarely exceeds an ounce. A number of illustrative cases were cited.

"A Case of Leucoplakia; Recovery," was the subject of a paper by Dr. W. C. Glasgow, of St. Louis, which was read by title.

DISCUSSION ON THE TREATMENT OF LARYNGITIS IN PROFESSIONALS WHO ARE UNABLE TO REST.

Dr. J. Solis Cohen, of Philadelphia, opened the discussion. When a professional has hoarseness the result of laryngitis and wants to use his voice in a few hours, the best method to enable him to do this, in his experience, is to administer a sharp emetic; then let the patient rest until the time of the performance, sucking pieces of ice and keeping a cold compress to the neck. In chronic laryngitis he had found nothing of so much service as a weak solution of sulphate of zinc (two grains to the ounce) used in a spray apparatus. In the intervals of the play the patient may inhale a little compound tincture of benzoin if he is hoarse. Another expedient of considerable service is the use of a respirator with turpentine, terebene, or eucalyptol, or something of that kind. He sometimes directs the patient to sprinkle a little turpentine on the floor of the bedroom, but was, however, not aware of any special method which is adapted to this class of individuals.

Dr. T. A. De Blois had had some experience with these cases, and had endeavored to keep up the systematic use of sulphate of zinc, but had found that the hoarseness continued unless the larynx is rested. Nitrate of silver gives excellent results, and the most disastrous results follow the use of cocaine. There seems to be a certain amount of relaxation following the use of muriate of cocaine.

In these cases we may conclude that unless there is rest there is no cure.

Dr. Beverly Robinson, of New York, said that his experience with the class of cases under discussion had led him to believe that, so far as the acute cases are concerned, there are milder measures than the use of an emetic. The use of tablet triturates of chloride of ammonium, repeated as often as once every fifteen minutes, is one of the most efficient methods of overcoming the difficulty. For local application there is nothing better than the carbolized spray. In the chronic form of laryngitis in vocalists we cannot obtain much information from the appearance of the mucous membrane. In these cases he had often found the membranes red, and this may continue after the trouble with the voice has disappeared. Here the difficulty is chiefly in the nervo-muscular apparatus. He found the internal use of a good wine of cocoa with the application of a faradic current to the neck very useful; the faradism to be repeated once or twice a day.

Dr. F. H. Bosworth, of New York, said that there is no such disease as laryngitis, as that term is used to mean an inflammatory process. The seat of the disease is not in the larynx, but in the nasal passages. If we apply cocaine to the nasal mucous membrane, causing contraction of the blood-vessels, and follow this by the use of chromic acid, thus eliminating the coryza, it will usually be found that the laryngitis has disappeared. Relaxation has been spoken of as following the application of cocaine. Although he had used the drug in many cases, he had seen this result in only two, and these were cases of hay-fever. His preferred method of using cocaine is to suspend it in fluid cosmoline and direct the patient to spray the nose and throat with it.

Dr. C. E. Sajous said that the action of cocaine in laryngitis is pernicious. In cold in the head it is useful, but should not be used within four hours of the time when it is desired to use the voice. In the majority of the cases of chronic laryngitis the condition is due largely to fatigue. Quinine and nux vomica internally, with the external use of a weak faradic current, are the best means to employ. Cocoa-wine is also advantageous.

Dr. W. C. Glasgow in this class of cases devotes himself entirely to the larynx and does not treat the nose. He usually employs applications of carbolized iodine to the larynx, which is a soothing application and relieves congestion. It also acts as a stimulant and enables the person to keep at his work; but it does not cure.

Dr. Morris J. Asch said that the best way to treat the acute cases is that which we pursue in other acute cases, which is the treatment suggested by Dr. Cohen except the emetic. The employment of muriate of ammonia is useful in solution in compound liquorice mixture. The chronic cases are more difficult to treat, because the patients cannot quit work. In them he had found nothing to equal the application of astringents. He had used the spray in some cases, but found that more good is done by the use of the brush. The solution which he most frequently uses is one of the perchloride of iron, thirty to sixty grains to the ounce. Where a person has to use the voice in a few hours, a single application will put him in a good condition temporarily. Another point to be considered is that these individuals live usually irregular lives, drinking wine and eating heartily. There is therefore nearly always some hepatic trouble which requires attention. He did not believe it possible to put the larynx of a singer in perfect order as long as he continues to work.

Dr. F. H. Hooper: In these professionals there is sometimes an alteration in the quality of the voice, the result of over-exertion, and owing apparently to a want of tension in one vocal cord. To relieve this he had used electricity outside, with the aromatic spirit of ammonia, thirty to forty drops to half a glass of soda-water, internally.

Dr. J. N. Mackenzie agreed with Dr. Bosworth with reference to the dependence of laryngeal disease on nasal trouble. The vast majority of cases of laryngitis are associated with disease of the nasal passages, and upon the recognition of this fact depends the successful treatment of many cases of chronic laryngitis. While admitting the existence of chronic primary laryngitis, he considered the majority of cases due to disease higher up in the respiratory passages. A caution is to be observed with reference to the indiscriminate use of cocaine in diseases of the nose and throat. It should never be applied just before a person is going to use the voice. The sensation which it produces in the larynx is only next to that of hanging. In the nose the effect is very pleasant, provided none of the solution be allowed to trickle into the larynx.

Dr. B. F. Westbrook, of Brooklyn: While it is true that many of these singers and elocutionists suffer from strain and overwork, it is probable that in the majority of such cases the seat of the whole trouble is in some derangement of the digestive apparatus which predisposes to these affections: therefore an emetic or active purgatives would be useful in many of these cases. After the emetic he usually gives small doses of the mineral acids, frequently repeated,—say one or two drops of dilute muriatic or nitric acid repeated every hour.

Dr. C. C. Rice, of New York, read a paper entitled "Glandular and Connective-Tissue Hypertrophies in the Lateral Walls of the Pharynx," advocating the employment of galvanism.

The next paper was by Dr. Charles H. Knight, of New York, on

THE GALVANO-CAUTERY IN THE TREATMENT OF HYPERTROPHIED TONSILS.

Among the objections to the cutting operation, the principal one is the danger of hemorrhage. Moreover, at times the tonsil is so deeply situated that it is not possible to get the tonsillotome over it. Patients sometimes positively object to the cutting operation. There are two methods of using the galvano-cautery: one is by puncture, and the other by the snare. The number of sittings required varies from five to ten, and not more than three punctures should be made at each sitting. The method with the snare is much the quicker. The current should be used intermittingly, and traction should only be made during the passage of the current. He did not recommend this as a universal operation, for in the majority of cases the cutting operation is easier and better. It is to be used where there is danger of hemorrhage; but in adults he was almost disposed to say that the galvano-cautery should always be used.

In the discussion the usual methods of treatment found advocates.

NOTE ON A FREQUENT CAUSE OF NASAL HEMORRHAGE. BY DR. BEVERLY ROBINSON, OF NEW YORK.

The ulcerations in cases of atrophic rhinitis had been a most frequent cause of hemorrhage in the experience of the speaker. He had found himself unable to detach the crusts from these ulcerations either by the use of douches or sprays, so well as by the employment of ointments. In the course of two or three days the patient is able to blow out the crusts. He had found no ointment act so well in imbibing the crusts and producing changes in the ulcerations as the ammoniated mercury ointment of the Pharmacopœia, of one-half or full strength, made up with vaseline. In applying plugs in the case of hemorrhage, he had found Steele's flexible probe useful, especially in children. He had found the so-called sheet-sponge a very good plug. This may be cut in long strips and pushed into the nostril until the bleeding is controlled by the pressure.

THE ASSOCIATION OF AMERICAN PHYSICIANS.

THE Second Annual Meeting of the Association was held in the Army Medical Museum Building, Washington, June 2 and 3, 1887.

On Thursday, June 2, the meeting was opened by an Address by the President, Dr. S. Weir Mitchell, of Philadelphia. He referred to the purposes of the Association as being purely scientific; it is not concerned about difficult ethical questions and medical politics. He hoped that all would endeavor to make the coming meeting of the Congress of American Physicians and Surgeons a success. He announced the death of three members during the year: Dr. Thomas F. Rochester, of Buffalo, Dr. Thomas A. McBride, of New York, and Dr. E. D. Hudson, Jr., of New York.

The first paper, entitled

CIRRHOSIS OF THE LIVER IN CHILDREN,

was read by Dr. R. Palmer Howard, of Montreal, who reported two cases in which cirrhosis of the liver was present in children,—brother and sister. He exhibited sections of the organ.

DISCUSSION.

Dr. William W. Welch mentioned one case in which cirrhosis had occurred in a child, 12 years of age, who came from the coast of Africa and suffered with malaria.

Dr. F. Forsheimer, of Cincinnati, had seen two cases that may possibly be called cirrhosis, which he attributed to syphilis: he thought syphilis the most common cause of cirrhosis of the liver in children.

Dr. William Pepper, of Philadelphia, mentioned a case in which cirrhosis of the liver followed measles in a child 8 years of age. There was no syphilitic history. During the attack of measles there were occasional attacks of catarrhal jaundice; subsequently the symptoms of cirrhosis made their appearance, and death soon followed. The whole duration of the case could not have been less than a year. At the autopsy a typical hob-nail liver was found. The liver had been much enlarged, but it had gradually contracted so that at the time of death it was of about the normal size.

OBSTRUCTIVE SAFETY-VALVE ACTION IN THE HEART AND DIRECT FUNCTIONAL MURMURS. BY JOHN GUITÉRAS, M.D., OF CHARLESTON.

The author had dwelt in a previous paper upon the significance of mitral direct presystolic murmurs, which were proved by the autopsy to be unconnected with any lesion of the mitral orifice. The lesions were those of intense aortic regurgitation. He had attributed the murmurs to the recoil of the blood upon the mitral leaflets holding them tense against the stream of blood coming from the auricle. In the opinion of the late Dr. Flint, direct functional mitral murmurs were limited to a small number of cases of aortic regurgitation, but the author thought that functional mitral murmurs were not so rare. Obstructive functional murmurs are common in aortic regurgitation.

Pulmonary systolic murmurs are more frequent than any other form of cardiac murmurs. In examining one hundred consecutive cases, he had found in sixty-two systolic pulmonary-artery murmurs. In these the murmurs were present during tranquil breath-

ing or during respiration in such a way as to produce changes in the pulmonary circulation. If account is taken of the bruits heard in this region the proportion becomes greater. The clearness with which these murmurs are heard depends upon the proximity of the artery, the thinness of the chest-walls, the nature of the surroundings, and, finally, the proximity of the main trunk to the capillary distribution. Systolic pulmonary murmurs can be developed in the majority of healthy individuals, if we exclude those with thick chest-walls and those who are not intelligent enough to modify their breathing as directed. The author held that such a murmur was a dynamic obstructive valvular murmur, and is produced by the effect of changes of blood-pressure upon the semilunar valves. A certain degree of pressure in the artery must tend to prevent the opening of the valve. This causes a slanting position of the valves and a narrowing of the orifice with the production of a sonorous whirl. The fact that such murmurs are not more frequently developed at the aortic orifice is due to the greater power of the ventricle and the wider distribution of the systemic circulation. There are, however, cases in which increased arterial tension is expressed not only by accentuation of the aortic second sound, but by an aortic systolic murmur. He had heard it in atheroma and in Bright's disease where there was no marked anæmia. Pulmonary-artery murmur as heard in ordinary breathing is confined to the expiratory act, and is loudest at the beginning of the act. The murmur is sometimes only heard with the first beat that occurs with expiration. In order to further develop this murmur it is only necessary to arrest respiration. It is better to stop breathing during expiration, especially at the end of normal expiration. A full expiration makes the murmur louder. At the end of inspiration it is more difficult to develop the murmur, for several reasons: 1, because it requires entire arrest of respiration to produce engorgement of the main trunk; 2, because prolonged inspiratory effort is accompanied by a continued hum of the intercostal muscles; 3, because the expansion of the lung interferes with the transmission of any murmur that may be present. A slight murmur is frequently heard in inspiration if the arrest of breathing is pushed far enough. The speaker asked, "Are we not justified in assuming that there is a safety-valve action in this attitude of the pulmonary valve which, together with the leakage at the tricuspid orifice, tends to prevent engorgement of the lungs by retardation of the flow of blood in the systemic veins, so that continued for a time it does no harm?" In reference to the murmurs of anæmia, the author thought that they were due to some disturbance of the valvular apparatus. In this condition there is a marked reduction in the quantity of blood. The valves require a certain amount of expansion of the vessels in order to allow them to apply themselves to the walls. Venous hums and basic murmurs he thought to be of valvular origin.

(To be continued.)

NEW REMEDIES AND CLINICAL NOTES.

Expectant Treatment of Extra-Uterine Pregnancy.—Dr. Beugnies-Corbeau, of Givet (Ardennes), describes in the *Union Médicale* of April 2 a case of extra-uterine gestation which had been left to nature owing to the mismanagement of a former medical attendant. He saw the patient in 1883. She was robust, and about 50 years old, and was subject to epistaxis. Twelve years previously she was pregnant for the first and last time. During her pregnancy she was subject to violent attacks of abdominal pain. Her physician believed that she was not pregnant, but that she had ovarian disease. At term she was seized with labor-pains. The physician came with all his instruments, and, after waiting for three days in the house without diagnosticating the case, went away believing, it seems, that he had to deal with an inflamed ovarian cyst or some kindred disease, which he was pleased to call "dropsy of the ovaries." After three years of ill health, an enormous abscess developed on the gluteal region, fragments of a fœtal skeleton came away through it, and a sinus was left which was very slow to heal. A second abscess opened in the same region on the opposite side, a third in the hypogastrium, and a fourth in the perineum. Both hip-joints became fixed apparently through muscular spasm. The last fistulous track discharged one of the scapulæ, which took five months in passing through the perineal structures. Being exceedingly tortuous, this fistulous passage remained open for two years. After so many years of suffering the patient was restored to perfect health. This case does not speak volumes in favor of the expectant treatment of extra-uterine pregnancy.

Corrosive Sublimate in the Treatment of Chronic Bright's Disease.—Dr. John C. Peters, of New York, says that in chronic catarrhal or tubal or parenchymatous nephritis milder remedies, like citrate or acetate of potassium, liquor potassæ, etc., may be tried first, aided by buchu. But sooner or later recourse may be had to corrosive sublimate, for which the fluid extract of buchu will prove a good and acceptable vehicle. It is also useful in some cases of cirrhosed or even lardaceous kidney, and there seems no special reason why it should not also be restorative in that most common and most important variety of kidney-disease,—viz.,

chronic diffuse nephritis. Its most obvious effect is an increase in the quantity of urine, which often rises from half a pint to three quarts and more per day, followed by a steady diminution of the dropsy and gratifying relief from all the most urgent symptoms. There will always be a large number of cases of kidney-disease in which no cure is possible, but only palliation and prolongation of life. Hence too much must not be expected, and a hasty rejection or abandonment of a good remedy should not be indulged in. For the kidney is not equally affected throughout all its parts, and the less injured portions may carry on reasonably well the depurative functions. We must conserve what is left of the kidneys. To get the full effect of corrosive sublimate upon the kidneys, salivation must be sedulously guarded against. The dose is one-twentieth to one-eighth of a grain with cinchona.—*Therapeutic Gazette*, December 15, 1886.

MISCELLANY.

THE Thirty-Eighth Annual Session of the Medical Society of the State of Pennsylvania was held at the Bedford Springs Hotel on June 29 and 30, and July 1, 1887. The account of this meeting will be published in our next issue.

DR. WILSON BUCKBY has removed to No. 1744 Diamond Street.

OFFICIAL LIST

OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U.S. ARMY FROM JUNE 19, 1887, TO JULY 2, 1887.

COLONEL CHARLES SUTHERLAND, SURGEON.—Granted one month's leave of absence, with permission to apply for an extension of one month. S. O. 126, Division of the Atlantic, June 23, 1887.

LIEUTENANT-COLONEL A. K. SMITH, SURGEON.—Will be relieved from duty at West Point, New York, on September 30, 1887, instead of on August 28, 1887. S. O. 144, A. G. O., June 23, 1887.

MAJOR J. C. MCKEE, SURGEON.—Granted three days' leave. S. O. 149, A. G. O., June 29, 1887.

MAJOR C. H. ALDEN, SURGEON.—Leave of absence extended to include September 29, 1887. S. O. 144, A. G. O., June 23, 1887.

MAJOR J. H. BARTHOLF, SURGEON.—Granted leave of absence for two months, to take effect about July 5, 1887. S. O. 141, A. G. O., June 20, 1887.

CAPTAIN CHARLES RICHARD, ASSISTANT-SURGEON.—Sick-leave extended two months on surgeon's certificate of disability. S. O. 139, A. G. O., June 17, 1887.

CAPTAIN JOHN J. COCHRAN, ASSISTANT-SURGEON.—Granted leave of absence for one month. S. O. 143, A. G. O., June 22, 1887.

FIRST-LIEUTENANT WILLIAM N. SUTER, ASSISTANT-SURGEON.—Designated as medical officer for the Rifle Camp at Creedmoor, New York, July 5, 1887. S. O. 124, Division of the Atlantic, June 21, 1887.

CAPTAIN GEORGE T. BEALL, MEDICAL-STOREKEEPER.—Granted four months' leave of absence. S. O. 150, A. G. O., June 30, 1887.

CAPTAIN A. V. CHERBONNIER, MEDICAL-STOREKEEPER.—Directed to take charge of office and perform duties of acting-assistant-medical-purveyor in St. Louis, Missouri, during absence on leave of Captain George T. Beall, Medical-Storekeeper, now performing those duties. S. O. 150, A. G. O., June 30, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U.S. NAVY FOR THE TWO WEEKS ENDING JULY 2, 1887.

MEDICAL-INSPECTOR C. J. CLEBORNE.—Ordered for examination preliminary to promotion as Medical-Director.

PASSED ASSISTANT-SURGEON G. P. LUMSDEN.—Ordered to Receiving-Ship "Franklin," Norfolk, Virginia.

MEDICAL-DIRECTOR P. J. HORWITZ.—Permission to leave the United States for six months.

ASSISTANT-SURGEON H. N. T. HARRIS.—Commissioned Assistant-Surgeon in the Navy, June 13, 1887.

MEDICAL-INSPECTOR J. C. SPEAR.—Detached from Naval Laboratory and granted three months' leave.

MEDICAL-DIRECTOR DELAVAN BLOODGOOD.—Detached from Naval Hospital, Norfolk, Virginia, and to the Naval Laboratory.

MEDICAL-INSPECTOR MICHAEL BRADLEY.—Ordered to Naval Hospital, Norfolk, Virginia.

PASSED ASSISTANT-SURGEON H. G. BEYER.—Remain on present duty until September 1, 1887.

PASSED ASSISTANT-SURGEON C. G. HERNDON.—Remain on present duty until June 17, 1888.

PASSED ASSISTANT-SURGEON C. W. DEANE.—Ordered to the Naval Rendezvous, San Francisco, California.

ASSISTANT-SURGEON H. N. T. HARRIS.—Ordered to the Naval Hospital, Mare Island, California.

MEDICAL-DIRECTOR A. C. GORGAS.—Remain on present duty until December 31, 1887.

MEDICAL-INSPECTOR C. J. CLEBORNE.—Remain on present duty until December 31, 1887.

SURGEON BENJAMIN F. MACKEY.—Remain on present duty until December 31, 1887.

MEDICAL-DIRECTOR J. MILLS BROWNE.—Will remain on present duty as member of Retiring Board until June 30, 1888.

MEDICAL-DIRECTOR RICHARD C. DEAN.—Will remain on present duty as member of Retiring Board until June 30, 1888.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U.S. MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDING JULY 2, 1887.

GUITÉRAS, JOHN, PASSED ASSISTANT-SURGEON.—Detailed for temporary duty at Key West, Florida, June 23, 1887.

WASDIN, EUGENE, PASSED ASSISTANT-SURGEON.—Relieved from duty at Marine Hospital, New York; ordered to Marine Hospital, Chicago, Illinois, June 23, 1887.

NORMAN, SEATON, ASSISTANT-SURGEON.—To proceed to Charleston, South Carolina, for temporary duty, June 23, 1887.

HEATH, F. C., ASSISTANT-SURGEON.—Relieved from duty at Chicago, Illinois, June 23, 1887.

ARMSTRONG, S. T., PASSED ASSISTANT-SURGEON.—Relieved from duty at Marine Hospital, Memphis, Tennessee; ordered to Marine Hospital, New York, June 27, 1887.

PECKHAM, C. T., PASSED ASSISTANT-SURGEON.—Relieved from duty at Marine Hospital, Wilmington, North Carolina; ordered to Marine Hospital, Memphis, Tennessee, June 27, 1887.

GLENNAN, A. H., PASSED ASSISTANT-SURGEON.—Ordered to Revenue Cutter "Crawford" for temporary duty, June 30, 1887.

BROOKS, S. D., ASSISTANT-SURGEON.—Ordered to examination for promotion, June 27, 1887; relieved from duty at Evansville, Indiana; ordered to Marine Hospital at Wilmington, North Carolina, June 27, 1887.

PHILADELPHIA, JULY 23, 1887.

ORIGINAL ADDRESS.

ANNUAL ADDRESS OF THE PRESIDENT OF THE STATE MEDICAL SOCIETY OF PENNSYLVANIA.

Delivered at the Annual Meeting held at Bedford Springs, June 30, 1887,

BY R. DAVIS, M.D.

WE are living in an age of tumultuous mental activity. Science and art have advanced with giant strides. In both variety and extent, as well as in rapidity of development, their attainments have been prodigious. We are amazed when we reflect that there are men still living, and possibly within the sound of my voice, who can recollect when London Bridge was first lighted with gas; when steamboats and locomotives made their first experimental trips; when the first announcement was made that light itself could be made to paint the picture which it renders visible to our eyes; that electricity could transmit news with the velocity of light across continents and oceans, and that it could banish night with a light as clear as that of day.

Imagine, if you can, the confusion bordering on chaos which would be precipitated upon the world if it were again suddenly deprived of illuminating gas, the steam-engine, the railroad, the ocean steamer, the telegraph, the telephone, electric lights, and the thousand other practical applications of science which have come within a few years!

Hardly less stupendous are the movements in the philosophical world. Truly has it been said of the Darwinian theory that "it was a revelation which startled the whole world. It shed a light on the science of life which necessitated a rewriting of its history, destroying at a blow many previous systems of thought." Similar great changes have been wrought in the religious thought of to-day, as well as in the science of government. Everywhere "old forms of belief are being assailed and are crumbling to decay. Old things are passing away; a host of ancient prejudices are tottering to their fall; and such is the rapidity with which we are moving that scarcely have they been levelled with the dust when new creeds spring vigorously from their ruins."

The science of medicine has not escaped the general upheaval of thought which has characterized other fields of mental activity. Here, as elsewhere, primeval faiths have been shattered, and ancient ideas have been made to give way to the speculations and discoveries of the day. Revolutions in medicine have been witnessed almost equalling in magnitude those wrought by steam and electricity. Vaccination and induced anæsthesia are discoveries which are entitled to be placed among the wonders of science, and in the same rank with the railroad and the telegraph.

Just now I asked you to imagine how great the confusion and loss which the world would suffer if it were now suddenly deprived of steam-power, electricity, and illuminating gas. That we may appreciate the great changes—nay, let us call them advances—which have been made in medicine in the same period, I now ask you to try to picture to yourselves what would be our condition as a profession if we were again deprived of the knowledge of the prophylactic power of vaccination; the knowledge of auscultation and percussion; the knowledge of renal pathology as inaugurated by Bright; the differentiation of typhoid from typhus fever; the discovery of the reflex system of nerves; the appreciation of the self-limitation of certain diseases and knowledge of their natural history; the use of medication by the hypodermic method; the discovery of anæsthesia and its application in medicine, surgery, and obstetrics; the creation of histology and gynæcology; the discovery of new methods and instruments of research and diagnosis, by means of the microscope, stethoscope, clinical thermometer, laryngoscope, ophthalmoscope, and electric light; the knowledge of the impunity with which the peritoneal cavity may be invaded for the removal of tumors, foreign bodies, collections of matter, and even for the repair and removal of injured or diseased organs; the great advances in hygienic knowledge and preventive medicine; and, finally, the more recent and vastly important revelations respecting bacterial etiology and antisepsis. All this and much more was as a sealed book to those who lived prior to the birth of the oldest man present to-night.

An age of such intense mental activity is one favorable to progress, and progress is everywhere visible. But it is also an age highly favorable to the development of *scepticism*, and that, too, is visible everywhere. It defiantly unfurls its banner upon every rampart of thought; it invades no less the domain of medicine than that of religion; it is rampant in our midst to-day; it pursues the physician everywhere,—to the seclusion of his study, to the assembly of his fellows, and, alas! too often, to the bedside of the sick, palsying there the hand that should be strong for succor.

The student of medicine cannot have proceeded far in his course ere he is made painfully aware of the existence among medical men of this feeling of a lack of faith in the power of remedies to control or favorably influence the course of disease. Every avenue of information open to him is more or less tainted with this scepticism. He encounters it in the teachings of professors of colleges, in the medical writings of the day, and in his intercourse with medical men. "The older I grow, the less faith do I have in medicine," says the physician of lifelong experience. "I am tired of imposing upon the public," is the reason given by another for retiring from practice. Others boldly disavow their belief in the potency of any remedy whatever, and deliberately state their belief that disease is infinitely better left to itself. One distinguished medical teacher, who is also poet, author, and wit, declares, "If all the medicines were cast into the sea, it would be all the better for men, and all the worse for the fishes." Another author, in a work devoted to a careful consideration of the question of how much art can accomplish in the cure of disease, concludes as follows:

"In only a very minute proportion of the numerous diseases presented to us in practice, and these few for the most part of slight importance, are we able to act positively on the diseased part or its morbid condition; while the whole large remainder of diseases can be only indirectly and distantly and slightly touched by our agents in any case, and in a large proportion of cases cannot be touched at all." And again, "Only in a minute proportion of cases can it be asserted with the certainty of truth that the mediation of art has saved life that would have been lost without its interference; in other words, has of itself positively *cured* disease."

There can be no mistaking this language of Sir John Forbes. Indeed, he strongly inclines to the opinion that, if the balance could be struck between the good and the evil done by medical interference, especially with the acute diseases, the evil would be found to preponderate. He graciously adds, however, that he would by no means infer from this that the services of medical men at the bedside can be dispensed with; an inference which, though it may not be entirely clear how it can logically follow, is yet very acceptable to those of us whose daily business it is to administer to the wants of the sick.

There is also much of scepticism lurking in what is said and written concerning nature's efforts to cure disease,—the *vis medicatrix naturæ*, as it is called. We are told that we must not interfere with nature; we must not place obstacles in her path or attribute to ourselves what belongs to her. Or, we must imitate nature, assist nature, guide nature, etc. There is often more in this to perplex than to instruct. What definite idea, for example, of the physician's duty at the bedside can be derived from the perusal of the following, which is from the pen of a distinguished author and teacher?—

"Unfortunately, the temptations of the physician to active interference with the course of disease seem to be irresistible, and hence he acquires the habit of treating nature as if she were a laggard in her duty and required to be smartly pricked at times to prevent her slumbering at her post." This, if it means anything, means that you should do nothing. Nature needs no prompting, no aid, no guidance, no support. Our mission is simply to *watch* nature.

But most of those who write in this strain admit that at times nature goes astray and needs the guiding hand of the physician; or she may need his aid in the curative efforts which she may be making; or she may become exhausted in the struggle, and when her powers begin to fail then it is the physician's prerogative to come boldly to her support.

A blatant sceptic recently expressed himself upon this subject as follows:

"A doctor's faith in physic is the measure of his intellect. It is always in inverse proportion. Confidence in God and

nature points to large comprehension. If we have been nature's adjuncts in her extremity, we have fulfilled our mission."

At the conclusion of a recently published paper on this subject by another writer I find the following: "The true physician is he who watches with intelligent eye, though often sparing hand, the course of disease towards health; who aids, when needed, the curative efforts inaugurated by nature, and who boldly, heroically supports the failure of vital organs at the crises of disease." But when I turn to the body of the article to learn what the author regards as evidence of the "curative effects inaugurated by nature," I find that the burden of his argument has been to prove that pain, fever, and inflammation are among the most beneficent of nature's therapeutic measures. Pain is nature's method of securing rest; fever is her means of killing the "disease-germs;" and inflammation is only nature's necessary means of repairing injury!

If, therefore, I would aid the "curative efforts inaugurated by nature," I must, I suppose, when pain is present, do what I can to increase it; or if fever, high temperature, exists, I must add fuel to the fire in order to make it too hot for the germs; and if inflammation, that most beneficent of all of nature's therapeutic measures, be present, I must "aid nature" by increasing its intensity!

Now, this may be an example of very advanced thought; it may be the "therapeutics of the future." But for the present I am free to say that I am not quite prepared to accept the new gospel, or to depart from the "good old way" of doing what I can to alleviate pain, to cool the hot blood of fever, and to quench the burning, destructive fires of inflammation.

What can we cure? is the momentous question which is thus forced upon our attention.

As we have seen, the answer which the extreme sceptic makes to the question is, virtually, "Nothing. Disease is better left to the natural physiological energy of the body, which is the only element in its cure." Others, less dogmatic, admit that "in a minute proportion of cases" some good may be done and lives saved by the intervention of art.

What is our answer to the question? Are we prepared to admit that we are all pursuing an *ignis-fatuus*, or that our power over disease is so inconsiderable? And especially are we willing to acknowledge that the evil done by treatment is more than enough to counterbalance the good?

* * * * *

Very different from the views of these sceptics are those still entertained by the people upon this subject. The popular belief continues to be that medication has a most important part to play in the cure of *every* disease. The public mind has not yet been disabused of the idea that for every bane nature has provided an antidote, and for every disease a curative leaf or root; and that when sickness comes the subject of it cannot possibly recover unless he "takes something" or "does something" to cure it.

Physicians have now come to know that this is an erroneous idea. We are all now tolerably familiar with the fact that many diseases are self-limited and tend intrinsically to recovery; and, therefore, that a large proportion of the cases of illness which occur among men would get well of their own accord and without any treatment whatever. Patent as this truth is to us now, yet it is one which the profession was long in recognizing.

It is only sixty-five years since Dr. Jacob Bigelow wrote and published his celebrated paper on self-limited diseases, and to that paper is generally accorded the credit of being the first to contain a distinct enunciation and demonstration of the truth that self-limitation is one of the laws that govern a large number of morbid processes. Subsequent investigation has served only to demonstrate more clearly the correctness of Dr. Bigelow's conclusions, and to lengthen greatly his catalogue of self-limited diseases. The great importance of this discovery is now generally conceded. It constitutes one of the most important epochs in the medical history of the century. Its influence upon therapeutics has been very great. It was the forerunner and great moving cause of that great change in practice, amounting to a veritable revolution, which consisted in the abandonment of what is known as the antiphlogistic treatment—blood-letting, purging, vomiting, mercurialization, counter-irritation, and starvation diet, including the withholding of cold water in fever—and the substitution therefor of what is known as the expectant treatment.

It is not my purpose to discuss the rela-

tive merits of these two plans of treatment, further than to express the conviction that, while the contribution to therapeutics of the expectant treatment has, in the language of Dr. Draper, "exposed many fallacies, dispelled many delusions, spared much needless suffering, and saved many lives," yet, on the other hand, it is itself chargeable with very grave errors, and has retarded in many ways the progress of the art of healing; and prominent among the evils it has engendered is this very scepticism in medicine which we are now considering.

The proneness of the human mind to run to extremes is well known. Having made the discovery that some diseases are self-limited, and being convinced that the old system of indiscriminate blood-letting, with large and frequent dosing, was in many cases not only unnecessary but productive of great harm, many medical men have rushed to the opposite extreme of therapeutic nihilism, allowing "nature," unaided and undisturbed, to continue on "in the even tenor of her way," thus embracing an error even more pernicious than the former.

Fellow-practitioners, how shall we convince, not the sceptics, for that would be a hopeless task, for sceptics in medicine, as elsewhere, deny established facts, and reject the evidences of their own senses,—but how shall we convince *ourselves* that our occupation is not entirely gone, that we still possess some curative power over disease, and that we are able, at least to some extent, by means of remedial measures to save lives that otherwise would be lost?

Several ways suggest themselves by which we may arrive at some conclusion upon this vital question of how many lives we are able to save by treatment.

For example, it would not be difficult, I fancy, to adduce from vital statistics convincing proofs that medical treatment, which in its widest signification includes not only the management of individual cases of illness, but also the prevention of disease and a supervision of the general bodily welfare, is capable of saving, and must be credited with having been the means of saving, many millions of human lives. It is claimed by statisticians that since the commencement of the present century human life in civilized countries has been prolonged more than thirty-five per cent., that the average duration of disease has been shortened fifty per cent., and that the average death-rate has been correspondingly lessened.

Sir T. Spencer Wells, in his inaugural address delivered last October before the Sanitary Congress, claimed that fifty years ago the average duration of life in Great Britain was about thirty years. *Now*, according to the healthy-life table, it is forty-nine years, a gain of nineteen years! It is certainly fair to conclude with him that a very large share of the credit for this very remarkable result is directly due to medical and sanitary works.

Some diseases, like the scurvy, once so wide-spread and destructive, and the plague, which in one year in London literally decimated the population, have in recent years, through the agency of medical science, been wellnigh banished from the civilized portion of the world.

Think also of the countless thousands of lives, to say nothing of the suffering and deformity, which have been saved by the discovery of vaccination alone.

A hundred years ago, epidemics of smallpox were as common and wide-spread as those of measles are now; and it was as rare for any one to grow up to manhood and womanhood without having suffered an attack of it, and bearing its ugly brand upon the person, as it is now to find an adult who has not had the mumps or the chicken-pox.

The mortality from this loathsome disease was then simply appalling. According to Professor Koch, of Berlin, one-twelfth of the human race was killed by it. In Sweden, according to the same high authority, eighty thousand people died annually of smallpox, while the number of deaths from this cause after the introduction of compulsory vaccination amounts to less than one thousand. Here, then, is a saving of seventy-nine thousand lives annually in that country alone by vaccination. Verily, therefore, has Jenner's discovery closed up one of the flood-gates of death.

Again, the records of hospitals throughout the world show that with the advance in medical knowledge and improved methods of treatment the rate of mortality in them has steadily and progressively diminished, not only in their surgical and obstetrical departments, but also in their medical. As proof that this diminished

mortality is in great part directly due to improved therapeutical methods, I might cite the records relating to typhoid fever in some of the great German hospitals. Those of the hospital at Basle are especially instructive.

From 1843 to 1865, which comprises a period when all therapeutic wisdom was supposed to have culminated in the expectant plan of treatment, the rate of mortality from typhoid was *twenty seven per cent.;* but since 1865, when active and systematic antipyretic treatment was adopted for this disease, the mortality has been reduced to *less than ten per cent.*

Other examples equally convincing might be given.

Another way of considering this question of how many lives we are able to save by treatment is in connection with the action of individual articles of the materia medica. Thus, it may be shown that Peruvian bark, since the discovery two centuries ago of its curative power in ague, has been the means of saving many millions of lives in this disease alone. It is claimed that in England, previous to the introduction of this remedy for intermittent fever, one in four and a half of all deaths was due to this disease, while after the use of this remedy and its alkaloid became generalized, only one death in three thousand was due to ague.

To appreciate the value to mankind of this drug, one needs to have lived in a distinctly malarious district during the prevalence of an epidemic of this disease, such as existed in many parts of Illinois in the fall of 1865, when so many were ill with it that it was found impossible to hold the courts, for want of judges, jurors, lawyers, clients, and witnesses; and as an illustration of the potency of this remedy I cite the fact that the notes of Dr. Dewitt, of White Hall, Illinois, show that for three months during the prevalence of this remarkable epidemic he found it necessary to make, on an average, but one and a half visits to a patient, including those ill with other diseases. In view of the great fatality of the disease and its tendency to continue indefinitely if left to go untreated by quinine, this result is one certainly not to be despised. Indeed, without quinine, many of the most productive parts of the world, and especially of our own great country, would be uninhabitable.

Opium is another drug which must be credited in a high degree with the life-saving power. One enthusiastic writer declares that "opium has assuaged more pain, soothed more sorrow, and saved more lives than all the other remedies in the materia medica." No fact in therapeutics is better established than that of the curative power of opium in peritonitis,—curative, that is, in the sense of arresting the disease and saving life.

And thus we might go on interrogating one agent after another,—alcohol, chloroform and ether, chloral, the bromides and iodides, mercury, ergot, salicylic acid, antipyrine, water, electricity, and many other agents; or we might extend the inquiry to whole classes of remedies,—the cathartics, the emetics, alteratives, tonics, diuretics, sedatives, antipyretics, and so through the list,—and the result of the inquiry could not fail to be to convince every candid mind that in something more than a "minute proportion of cases" we are able with these agencies so to act upon the various organs of the body as to cure diseased conditions and avert impending death.

But probably a truer estimate of the value of medication may be obtained by considering the subject in connection with the objects which the physician aims to accomplish by treatment. Measures of treatment such as are resorted to when disease already exists in the body are either abortive, curative, palliative, or supporting.

With reference to the first, it must be admitted that with our present knowledge the range in which abortive measures are effective is not very large. Quinine will abort an ague, and morphine given hypodermically will abort cholera morbus. Many contend also that opium given in the first stages of epidemic cholera will in a great number of cases "nip in the bud" that dread disease. Our fathers also believed that many of the acute inflammatory diseases could be arrested in their incipiency by a copious bleeding; and it is worthy of note that not a few of the ablest and most conservative thinkers of the present day are beginning to believe that they were more than half correct in their conclusions. It is especially worthy of note that the late Dr. Austin Flint, the great apostle, as was claimed, of conservatism in treatment, who was even accused, though unjustly, of a leaning towards therapeutic nihilism, had, in the last

communication which he was privileged to make to the profession,—the great address prepar d for the British Medical Association on "Medicine of the Future,"—placed on record his belief that "by the abandonment of blood-letting a useful measure of treatment was given up," and he confidently predicted that "the time will come—and that ere long, for it is now foreshadowed—when it will have its proper rank among therapeutic agencies." These remarks concerning blood-letting he made "with the understanding that they are, to a greater or less extent, applicable to the other so-called antiphlogistic measures."

The acknowledgment must be made, however, that the vast majority of acute affections are insusceptible of being suddenly arrested in their course by any remedies now known to us. The great error underlying the system of treatment pursued by our fathers in these cases consisted in their always making violent efforts to expel or throttle the disease by means of "medicinal dynamics:" all their efforts being directed towards the discovery of specific remedies.

The main battle-ground between the modern sceptic and the rational therapeutist is reached when we come to the consideration of *curative* measures of treatment. The sceptic contends that for the acute inflammatory and infectious diseases especially we have no curative agents. These he says are self-limited diseases, and will run their course uninfluenced by medication.

On the other hand, the rational therapeutist, while admitting their self-limited character, that the majority of cases will recover without treatment, and that, with the exception of quinine in ague, mercury and iodine in syphilis, salicin in rheumatism, opium in certain inflammatory and spasmodic diseases, and a few others, no *specifically curative* agents are known to us, is by no means willing to admit that therapeutics can render him no aid. Remembering that without treatment a large proportion of these cases will terminate fatally, the task which he sets for himself is to prevent this mortality. He now bends all his energies not so much to arresting the course of the disease as to *bringing his patient through it alive.*

Liebermeister says, "The disease will come to an end without any of our assistance; but the special business of the physician is to see to it that the patient outlives the disease. And this duty," he continues, "can often be accomplished by the application of symptomatic treatment in its wider sense, as well as through dietetic regulations. On the one hand, we must see to it that the usual incidents of the disease, if they show a tendency to grow especially burdensome or dangerous, as well as any suspicious accidental developments, are held within check, and so far as possible weakened in their power; on the other hand, we must strive to maintain the patient in such condition that he shall be able to offer the longest and the strongest resistance to deleterious influences of which his constitution is capable."

This is an admirable presentation of the principles which should govern our conduct of these cases. The statement that the physician should "see to it that the patient outlives the disease" is a truth which every practitioner, but especially every doubting Thomas among us, should have indelibly engrafted upon the mind.

Give specifics whenever you have good reason to believe in their existence; throttle the disease in its incipiency whenever you are sure it can be done; but when, as is generally the case, you are satisfied that this cannot be accomplished, then turn your attention to the patient, and "see to it" that he does not die before the disease has spent its force.

An important principle to be observed in the accomplishment of this object is that we should bend every effort to secure for the patient as nearly a normal condition as possible. In other words, the more comfortable we can make him, the more sleep we can secure for him, the more naturally his secretions are maintained, the more sure is he to recover.

Permit me a single illustration. Given a case of typhoid, scarlet, puerperal, or other fever, in which excessive elevation of temperature is a principal source of danger. The patient's temperature is 105°, his tongue is dry, he is wakeful, restless, and wildly delirious. You administer a full dose of antipyrine, with cold sponging, and in an hour his temperature is reduced to 102°, he perspires, his pulse softens, his tongue moistens, his delirium vanishes, and he falls into a refreshing sleep, lasting several hours. Is it possible that this is not an important factor in conducting the case to a successful issue? To conclude

otherwise is to disregard the teachings of experience and to violate the dictates of common sense. Granted that the fever with all the other distressing symptoms will return again and again, and the disease continue on unabridged in its duration; yet it cannot be that the drain on the vital energies produced by the high temperature will not be lessened, and thus often the vital spark be preserved which otherwise would be utterly extinguished. So even is the balance often between life and death in severe cases that a single respite of a few hours from distressing symptoms, such as active antipyretic treatment is capable of securing, is sufficient to turn the scale in favor of a restoration to health.

Call this expectancy if you will; but it is not that kind of expectancy which consists in a mere passive waiting on events, or which is inconsistent with "active interference with the course of disease," or which forbids our "treating nature as if she were a laggard in her duty and required to be smartly pricked at times to prevent her slumbering at her post." On the contrary, it is that kind of expectancy which admits of the use of the most potential medicines, not excepting the old abandoned antiphlogistic measures of blood-letting, purgation, and the rest,—provided that the one grand object be attained of preserving the patient's life until the disease ends. And the triumph of the physician who does this, if not quite so brilliant, is yet just as real as if he had throttled the disease in its incipiency. The mariner who amidst the storm steers his craft so skilfully as to prevent her being submerged by the waves or dashed against the rocks has just as truly saved the lives of those on board as if he had said to the winds and the waves, "Peace, be still," and been obeyed.

Measures of treatment instituted with a view to guarding against any dangerous accidental developments have a wide field of application, and when skilfully applied result in a vast saving of life. Measures used to prevent perforation of the bowels in typhoid fever, and to guard against systemic infection in diphtheria, are examples of this class.

But the most conspicuous example of their use, the one attended with the most brilliant results, is seen in the application of the principles of antisepsis to the surgical dressing of wounds. The accounts given of the results attained by this treatment in our hospitals read like a fairy-tale. Operations fearlessly undertaken which, even ten years ago, were regarded as without the pale of legitimate surgery; compound fractures made to unite without suppuration; amputation and resection wounds healing without the formation of a single drop of pus, and with a single dressing; large cold abscesses opened and their cavities made to close without further suppuration; large, deep arteries tied and the wounds permanently closed without fear of secondary hemorrhage; pus as an outcome of surgical operations a thing of the past; septicæmia, pyæmia, and erysipelas banished from the wards,—such is the account everywhere given of the results of this treatment. Verily, Listerism has revolutionized the art of surgery, and enables us now to save thousands of lives which, under the best treatment which prevailed even ten years ago, would have been lost.

But why should I longer weary you with attempts to point out the many ways in which remedial measures may be made available in the cure of disease? I could not hope, if that were necessary, to go over the whole ground. That I have not done so is evident from the fact that I have said little or nothing of what may be accomplished by the surgeon, the obstetrician, and the gynæcologist. I have said nothing of the large number of curable chronic diseases, which, though not all necessarily fatal when not treated, yet tend to continue on indefinitely and make life a burden. Neither have I attempted to point out how life may be prolonged, and existence made more tolerable, while it lasts, for those afflicted with confessedly incurable or necessarily fatal diseases. But I trust I have said enough to warrant me in saying—which I feel I may do in the name of this great Society—that there is absolutely no just ground for the existence of the pessimistic views of medicine which I have been combating.

While acknowledging that our art has not yet reached that degree of perfection which we all desire to see it attain,—that there are, alas! yet too many diseases over which we possess little or no curative control,—yet we contend that we are day by day making rapid strides towards the attainment of that perfection, that the number of incurable diseases is constantly diminishing, that the science is daily be-

coming more practical and the art more scientific, and that now enough of good can and is being accomplished by its instrumentality to justify the warmest enthusiasm of its votaries, and to entitle it to a place first in importance to mankind in the catalogue of arts.

It ought to require no argument to prove that scepticism in medicine is a great evil, and a hinderance to progress. I cannot conceive how a sceptic can be a good physician. He may be profoundly versed in the history and pathology of disease, but, as Broussais has well said, "the real physician is the one who cures; the observation which does not teach the art of healing is not that of a physician; it is that of a naturalist,"—a truth which I would especially commend to the consideration of those teachers of the theory and practice of medicine who spend hours in describing the lesions and natural history of disease and dismiss the principles and means of cure with few and distrustful words.

The sceptic in medicine must not only be devoid of enthusiasm in his work at the bedside, but he must also be lacking in resources, and "a physician without resources is a soldier disarmed: he inspires no confidence."

What man of us would not choose, if he were ill, to trust himself to the care of a physician who, like my gifted and scholarly friend and fellow-townsman Dr. Mayer, believes that "we have now means and remedies capable of controlling all the remedial morbid conditions of the human frame," and that "the success of modern medicine in the hands of cultivated practitioners is a matter of marvel, and is nearly all that we can desire,"—who, I say, would not sooner trust his life to a physician of such *large* faith, rather than to one who mockingly declares that the measure of a doctor's intellect is in inverse proportion to his faith in medicine?

I will close this address, already grown too long, by bringing before you a picture of the ideal physician drawn over fifty years ago by one of the ablest physicians and most attractive clinical teachers of the century, Latham, simply remarking that I cannot conceive it possible for a transcendent therapeutic doubter to become such a physician as is here described:

"Diseases are not abstractions; they are modes of acting, different from the natural and healthy modes,—modes of disorganizing, modes of suffering, and modes of dying; and there must be a living, moving, sentient body for all this.

"This body must be your study and your continual care,—your active, willing, earnest care. Nothing must make you shrink from it. In its weakness and infirmities, in the dishonors of its corruption, you must still value it, still stay by it, to mark its hunger and thirst, its sleeping and waking, its heat and its cold, to hear its complaints, to register its groans.

"And is it possible to feel an interest in all this? Ay, indeed it is; a greater, far greater, interest than ever painter or sculptor took in the form and beauties of its health.

"Whence comes this interest? At first, perhaps, it seldom comes naturally; a mere sense of duty must engender it; and still, for a while, a mere sense of duty must keep it alive. Presently the quick, curious, restless spirit of science enlivens it, and then it becomes an excitement, and then a pleasure, and then the deliberate choice of the mind.

"When the interest of attending the sick has reached this point, there arises from it, or has already arisen, a ready discernment of diseases, and a skill in the use of remedies. And the skill may exalt the interest, and the interest may improve the skill, until, in the process of time, experience forms the consummate practitioner.

"But does the interest of attending the sick necessarily stop here? The question may seem strange. If it has led to the readiest discernment and the highest skill, and to form the consummate practitioner, why need it go further?

"But what if humanity should warm it? Then, this interest, this excitement, this intellectual pleasure, is exalted into a principle and invested with a moral motive and passes into the heart. What if it be carried still further? What if religion should animate it? Why, then, happy indeed is that man whose mind, whose moral nature, and whose spiritual being are all harmoniously engaged in the daily business of his life; with whom the same act has become his own happiness, a dispensation of mercy to his fellow-creatures, and a worship of God.

"Such a man any of you may be; but you must begin by learning to stand at the sick-bed and make it your delight."

ORIGINAL COMMUNICATIONS.

OVARIAN TUMOR COMPLICATING PREGNANCY.

Read before the State Medical Society by title

BY E. E. MONTGOMERY, M.D.,

Professor of Didactic and Clinical Gynæcology in the Medico-Chirurgical College, Obstetrican to the Philadelphia Hospital, etc.

THE field of ovarian disease has been so often gleaned that the hasty observer may deem it impossible to cull anything new therefrom. While I do not, in this paper, make any pretence to special originality, I hope to be able to present what experience teaches to be the most successful method of treating "Pregnancy complicated by Ovarian Tumor."

It may be questioned whether this complication is frequent enough to render the subject of sufficient importance to occupy the time of this scientific body. Its frequency may be appreciated when I am able, from a very cursory investigation of the literature, to present tables of over one hundred and fifty cases.

Ovarian disease does not preclude the possibility of conception so long as the ovaries contain healthy ovarian stroma.

In Spencer Wells's first one thousand cases of ovariotomy over two hundred children have since been born. A woman upon whom I did ovariotomy in the Philadelphia Hospital in 1879, whose second ovary contained so many cysts that its removal was debated, has been treated in the same institution for abortion. Schroeder, with the knife, and Pippingskoeld, with the galvanic cautery, have destroyed the cystic tissue of the second ovary, and the woman subsequently became pregnant. Indeed, rare instances have shown that the removal of the ovaries is not an absolute safeguard against conception. In such cases there are undoubtedly rudimentary masses of ovarian stroma or supplementary ovaries.

This probability of subsequent conception is a strong argument for the preservation of the second ovary during the period of sexual activity. Instead of complete extirpation, we should follow the course of Schroeder and Pippingskoeld.

The investigations of Jetter have shown that any form of ovarian cyst may complicate pregnancy. Of his collection of one hundred and sixty-six cases, ninety-seven were cystomata, thirty-seven dermoid, eleven carcinomata, and twenty-one uncertain. In a majority of the cases the tumor had existed for a length of time before pregnancy.

It is frequently asserted that owing to the pelvic hyperæmia consequent upon pregnancy the growth of these tumors is greatly accelerated. This growth, however, is probably more apparent than real. The great distention and distress are due to the natural growth of the tumor, plus the accompanying development of the uterus. Wernich not only accepts the accelerated growth as an established fact, but asserts that benign cysts, during pregnancy, are more likely to take on malignant action. Ruge explains the latter by claiming that the malignant element was originally present.

The dermoid cysts, from their smaller size, are most frequently found in the true pelvis.

The situation and size of the tumor are of marked significance in determining the prognosis. Of seventy-five cases, including those of Playfair, the tumor was found in the recto-vaginal septum in forty-one, on the right and left sides each five times. When small, the growths may frequently be overlooked, and the hinderance to delivery remain undiscovered or be ascribed to pelvic narrowing. Grigg's post-mortem researches in puerperal septicæmia render it probable that many cases of this disease are due to injury of unrecognized ovarian tumors during parturition.

The diagnosis of the coexistence of pregnancy and ovarian tumor is of the greatest importance, and oftentimes a difficult problem, but the limits of this paper will not permit of its discussion.

The mortality of ovarian tumor complicating pregnancy treated by the expectant plan is frightful. In the seventy-five cases culled from literature, thirty-one, or forty-one per cent., were fatal, while but twenty-two children, or twenty-nine per cent., are quoted as having been saved. The maternal mortality differs but little from that given by Litzman,—maternal, forty-three per cent.; fœtal, eighty-three per cent.

Such a death-rate urgently demands the investigation of other plans of treatment. When we come to the consideration of ovariotomy during pregnancy, we find far better results.

In the accompanying table of sixty-one cases, but seven, or less than eleven per

cent., were fatal; thirty-nine went to full term, or reached the period when the child became viable. The comparison of the results of ovariotomy (maternal mortality twelve per cent., fœtal mortality thirty-five per cent.) with those of the expectant treatment (maternal mortality forty-three per cent., fœtal mortality eighty-three per cent.) unquestionably demonstrates the value of the former. It is seen that the presence of pregnancy does not materially enhance the danger of ovariotomy. Further, it is rendered prominent that after performing ovariotomy the prognosis is extremely favorable for mother and child.

Finding that ovariotomy can give such good results, it remains then to be taken in consideration in each individual case.

The following points naturally present themselves for discussion:

1. Is ovariotomy the most secure and best proceeding for the removal of the complication?

2. Shall one in all cases do ovariotomy?

3. When is the most favorable time for its performance?

Those having large experience, as Spencer Wells, Tait, Cauchois, Olshausen, and the late Carl Schroeder, unite in commending ovariotomy as the most desirable proceeding. Most agree that it should be done at once in recognized ovarian tumor during pregnancy, on account of the danger of rupture of the cyst, twisting of the pedicle, exhaustion of the patient from the great abdominal distention, the possible complication of labor from the presence of the tumor, and the greatly increased mortality where ovariotomy is required during the period of puerperal convalescence. Its early performance is especially important when we take in consideration that Cohn has proved every sixth tumor to be probably malignant.

With the experience before us of the late Carl Schroeder, of fourteen cases and no deaths, Spencer Wells and Tait each eleven cases with one death each, the presence of pregnancy should hasten rather than retard the performance of ovariotomy.

The sixty-one cases of the accompanying table, with a mortality of eleven per cent., show that, while pregnancy does not improve the prognosis, it certainly does not make it worse.

Next to ovariotomy, tapping has always been more or less employed. Our first table will show that it is just about as dangerous and as free from danger as ovariotomy, with the disadvantage that it is not a radical operation. It is still further unsatisfactory in that it increases the danger of subsequent ovariotomy, and that there is greater danger of wounding neighboring organs. Artificial labor is now but little performed, for the reasons that it does not preclude the necessity of ovariotomy and that it diminishes the chances of the fœtus. Abortion and tapping do not preclude ovariotomy, but rather augment the necessity of its performance under unfavorable circumstances. If, then, in the complication of ovarian tumor with pregnancy, ovariotomy gives clearly better results than either the purely expectant treatment upon the one hand or tapping and abortion on the other, it is the most secure and best proceeding. But shall we do ovariotomy in all or only in isolated cases?

The answer to this question is the following: one must, in all cases in which ovarian tumor has been diagnosticated, do ovariotomy, because—

1. Ovariotomy is unavoidable, and the prognosis is not made worse by the existence of pregnancy.

2. The labor and convalescence with the tumor offers a far more unfavorable prognosis than without it.

3. Many tumors are malignant, although we cannot certainly so diagnose them; and it is difficult to say how far the spreading of the malignant element is favored by pregnancy and the resorption in convalescence.

The most favorable period for operation, as recognized by all operators, is during the first half of the pregnancy. In the last months, the increased hyperæmia and engorgement of the broad ligaments render it less favorable. Then, too, there is more probability of the convalescence being complicated by premature labor. The experience of a number of operators, as quoted in the table, shows that the operation can be performed in advanced stages of pregnancy with good results. The case of Pippingskoeld, in which it was performed during labor, is eminently encouraging.

My own experience (limited to one case) has led me to question whether, in the last stages of pregnancy, it would not be better to follow the excision of the ovarian tumor

by removal of the contents of the uterus through Cæsarean section.

The history of the case to which I allude is as follows. April 4, 1886, I was called in consultation with Dr. George Mays, to see Mrs. N., aged 24 years. She had been married less than a year, and had ceased to menstruate August 15, 1885. The menstrual function had become established during her thirteenth year, and, while regular, had always been scanty. For the past year she had had considerable distress and sense of weight in the pelvis, with occasional attacks of difficult micturition amounting, at times, to retention. The sensation of weight was greatly increased after marriage, but very naturally was attributed to pregnancy. At the date mentioned she believed herself in labor. She was complaining of severe pain, and the doctor informed me that upon digital examination he could not find the os. He had also unsuccessfully attempted to catheterize her. Inspecting the abdomen, the uterus was seen distending it as high as the ensiform cartilage; below, reaching nearly to the umbilicus, was a second spherical tumor which fluctuated and was evidently the distended bladder. By the vagina was felt a moderately elastic mass, filling up the curvature of the sacrum and reaching to the symphysis in front. I first supposed it a case of pregnancy in marked anteflexion of the uterus, in which we would find the os uteri situated high up; pushing the finger well up forward, I could reach the cervix just above and behind the symphysis. The os was undilated. The pressure of the cervix upon the neck of the bladder was the cause obstructing urination. By means of a male catheter nearly two quarts of urine were drawn off. The pelvis was filled up with a smooth round tumor which had pushed the bladder and uterus completely out of the pelvis. A rectal examination disclosed some projections from the cyst, showing that it was not a single cyst, although unmistakably of ovarian origin. Failing in the effort to push the tumor up while the patient was in the genu-pectoral posture, we were confronted by the necessity of relieving her of its presence to permit the expected delivery. She had now about reached the eighth month of pregnancy. Should we induce premature labor? This would not be possible unless the tumor was simultaneously reduced. Tapping was thought unwise, for the reason that the majority of these intra-pelvic ovarian growths are either dermoid or multilocular cysts, with very viscid contents. Our examination had shown the growth to be multilocular. The escape of its contents into the pelvic cavity would insure the development of peritonitis, and this would be still further aggravated by the bruising of the sac in the passage of the fœtus over it. Accordingly, it was thought better to do ovariotomy.

After thorough disinfection of the room, assisted by Drs. Mays, Warder, Eshleman, and West, the operation was performed, April 10, 1886. Beginning one inch below the umbilicus, an incision five inches long was made towards the symphysis. The left hand was passed between the left abdominal wall and uterus, behind and below the latter, until the cyst was reached. A small cyst projected above the pelvis and ruptured under the pressure of the hand. Dr. Mays introduced his hand into the vagina to facilitate the delivery of the larger cyst. It also ruptured under the pressure. The sac was raised up, and, having its origin on the right side, it was passed behind the uterus to the opposite side. Its pedicle was ligated with the Staffordshire knot, the tumor removed, the abdomen carefully cleansed, the wound closed with silk sutures. The wound was dressed with sublimated gauze and absorbent cotton. The operation was completed in forty minutes. The left ovary presented a cyst the size of an orange, but it was thought best not to remove it.

The night following the temperature was 102.2°, but soon subsided, not again reaching 102°, becoming normal on the fourth day. On the seventh day the sutures were removed and the dressing renewed. The central portion of the integument was ununited, the sutures having cut out. This was supported by adhesive plaster. A few hours later labor set in. This occurred during my absence. Dr. Mays, seeing serum oozing from the abdominal opening, applied the forceps and delivered a strong, healthy child. As the forceps were applied with the patient lying upon her back in the centre of the bed, the vulvar orifice was necessarily considerably lacerated. When I saw her about an hour after the labor, she was very much exhausted and had lost considerable blood. The second day following the temperature

began to rise, the lochia became offensive, the abdominal wound opened, and offensive serum was discharged. Intra-uterine injections were given, and the abdomen washed out with chlorinated soda and listerine, but despite all our measures the septic symptoms continued, and death occurred April 24, two weeks after the operation. It has since been a regret that while the abdomen was open I did not remove the contents of the uterus and close the uterine wound with sutures, after Sänger's method. I am encouraged to believe such a course would have been successful from those cases of Wells and Byford in which the uterus was injured during ovariotomy and emptied of its contents. In Byford's case the pregnancy had reached the eighth month. My patient showed no septic symptoms until after the delivery, and by the course suggested this source of origin would have been avoided.

Braxton Hicks —Six cases left to nature; all did well.
Barnes saw death in one case from cyst-rupture at seventh month; in another peritonitis caused death.
Rogers saw five cases: one tapped before delivery, mother and child lived; a second went to full term, mother and child did well; three premature labors, all mothers lived.
Chadwick.—Three cases, non-interference; all recovered.
Battey.—Four cases, non-interference; three died from cyst-rupture; one died from abortion.
Sutton.—Two cases in which death followed abortion from twisted pedicles.

REPORT ON RECENT STUDIES ON DISEASES OF THE CIRCULATORY APPARATUS.

BY J. P. CROZER GRIFFITH, M.D.

(Continued from page 666.)

THE PULSE—Continued.

II. VARIATIONS OF TENSION.

LOW Tension.—Tension depends primarily on the resistance in the arterioles and capillaries. This resistance may be so slight that venous pulsation may be produced (differing in origin from that seen in aortic disease). The characteristic low-tension pulse is abrupt and short, and the artery is flattened completely between the beats. It may be dicrotic, undulatory, strong or weak, large or small. Pyrexia almost constantly relaxes the capillaries; hence there is low tension in fever. In the absence of fever, a pulse of low tension, unless it be a physiological peculiar-

ity, indicates cardiac weakness (not fatty heart, in which the pulse is usually slow). The symptoms are not characteristic. In this condition purgatives give rise to depression.

High Tension.—High tension of nervous origin, as in hysteria, cerebral and spinal diseases, rigors, and the cold stage of fever, is probably due to a spasm of the arterioles; while in that of blood-origin, as in renal diseases and allied conditions, the trouble rests chiefly with the capillaries. This conclusion is based on various grounds, which the author explains. The characteristic high-tension pulse is the *pulsus tardus*, slow and long. It may be either small or large. If the heart is weak, the artery will be *compressible* and yet *cord-like.* To this condition Broadbent applies the term "virtual tension." In it the access and subsidence of the pulse seem to be sudden and the pressure to last a certain time between them. Virtual tension is met with at the onset and at the close of renal disease, and is the characteristic pulse of dilatation of the heart. The causes of high tension are: (1) Heredity. (2) Kidney-diseases of all kinds except suppuration. (3) Gout and allied disorders, including affections attributed by Murchison to functional derangement of the liver. (4) Lead-poisoning, with or without renal disease. (5) Anæmia. In this it is certain that the tension is usually high. Cases of anæmia with very low tension are rare. The causes of the difference are not known. (6) Pregnancy. (7) Constipation. (8) Plethora. (9) Chronic bronchitis and emphysema.

The effects of high tension are hypertrophy or dilatation of the heart. Some contributory exciting cause usually co-operates to produce dilatation. Valvular changes, dilatation of the aorta, and cerebral hemorrhage are all results of high arterial tension. This tension is often overlooked in valvular disease, and cannot but throw still greater strain on the affected valve. It may be best detected in aortic insufficiency by feeling the pulse when the hand is well below the level of the shoulder, but not hanging down; and in mitral disease by trying it with the hand in different positions. Cases of kidney-disease (especially large white kidney) may occur without any tension whatever, there being less than the normal resistance in the arteries and capillaries. The prognosis in such cases is most unfavorable. Indeed, in acute albuminuria a favorable prognosis depends on the rapidity with which high arterial tension develops. In contracted kidney high tension is very rarely absent.

Functional Effects.—High tension may produce the most severe angina pectoris, or sudden dyspnœa, as though there were advanced heart-disease. Intermittent albuminuria is often due to it, combined in children with a strongly neurotic family history.

Treatment.—This is often not needed. Bleeding is a powerful means to reduce tension, and is usually used only in extreme cases. It is useless after cerebral hemorrhage has occurred, but might save hundreds of lives if employed to reduce tension as a preventive measure. Tension can also be lowered by reducing the force of the heart or the peripheral resistance. The latter is the proper method, and may be accomplished either by relaxing the arterioles by nitro-glycerin or the nitrites, or, better, by eliminating from the blood, by diuretics, diaphoretics, or purgatives, the nitrogenized waste which, by its irritation, provokes the obstruction in the artero-capillary circulation.

THE PULSE IN HEART-DISEASE.

Aortic Stenosis.—The pulse in this affection is gradual and long, owing to the obstruction to the rapid flow of blood. It is small, full between the beats, and destitute of impact. When typical, it is one of the most peculiar pulses met with.

Aortic Regurgitation.—This pulse is too well known to require description. The author calls particular attention to the element of size, to the falling away of the blood-column when the arm is held up, and to the great increase of the collapsing character under the influence of pyrexia. The slightest departure from regularity is ominous.

Mitral Regurgitation.—This pulse often presents great irregularity, but this does not always indicate a dangerous failure of compensation.

Mitral Stenosis.—The pulse is regular, small, and full between the beats. When the heart fails, irregularity appears at the wrist, while the heart-beats are still regular in time. Finally, the irregularity of the pulse and its lack of correspondence with the irregular heart defy description.

The pulse of *hypertrophy* is that of its cause, and that of *dilatation* has been already described.

III. THE PULSE AND CEREBRAL AFFECTIONS.

Broadbent considers under this head only the effect produced on the brain by abnormal conditions of the circulation, omitting the converse of this.

Sleeplessness is due to many causes, and among others to the disturbed condition of the circulation. The first of these is high tension, virtual or actual. The immediate cause here probably is the inability of the tired arterioles of the cortex to shut off the pressure and produce the requisite anæmia. A mild mercurial aperient is the most efficient hypnotic, and sleep is obtained in an hour or two after its administration. Hot bathing, general or local, and a variety of other measures are also useful.

The second condition is an extremely low tension. This is a common cause in men of middle life and sedentary occupation. The patient has often an irresistible desire to sleep during the day, but cannot rest at night. He can sleep while sitting, but not when in the recumbent position. The pulse is variable, the heart weak, the arterioles relaxed, and hence while sitting the brain is anæmic, but while lying the vessels are overdistended. A tonic plan of treatment, with change of air, is indicated.

Convulsions and the Pulse.—Convulsions may attend exactly opposite states of the circulation. Death in convulsions may occur in rapid hemorrhage and in asphyxia, *i.e.*, from excessively low or unduly high arterial tension, tubercular meningitis, by the pressure of the effusion obstructing the circulation. Even slight causes may produce temporary arrest of the circulation. The author narrates two cases in adults where unconsciousness was repeatedly produced by paroxysms of coughing; and another in which convulsions appeared to be due to the increased intra-cranial pressure resulting from a thickening of the frontal bone. He follows this with a series of cases in which high arterial tension produced convulsions, and the patients were relieved by a reduction of the tension by therapeutic means. Uræmic convulsions are probably due as much to the high tension as to the poisonous matter. There is no doubt, at any rate, that blood-letting has often a remarkable effect in cutting them short.

Low arterial tension is much less commonly associated with convulsions. The author reports several cases, in one of which convulsions were brought on by every attempt of the patient to sit up.

It may be that a careful study of the pulse may throw some light on the forms of epilepsy and their treatment. Broadbent has been led by his experience to conclude that in essential epilepsy the arterial tension is low and variable or fluctuating. During pregnancy the fits often cease; and it is one of the effects of this condition that the arterial tension is increased. Epilepsy associated with high arterial tension usually comes on later in life, and is more amenable to treatment.

Violent maniacal delirium may be dependent on high tension of the pulse. The author has seen several instances of this.

Pulse and Melancholia.—The connection between melancholia and its allied mental states on the one hand, and the condition of the circulation on the other, is more direct and decided than can be traced in epilepsy. Senile melancholia is probably due to functional disturbance from an impeded circulation. Again, a family tendency to melancholia may be due to hereditary high tension of the pulse, and complete recovery in such cases shows that there has been no structural change. Protracted arterial tension may be, if not the cause, at least the index of the condition on which the mental state depends. It is probable, as the capillaries thicken as a result of high tension which has lasted for years, and the heart ceases to gain in strength, that the brain no longer receives a proper supply of healthy blood. At any rate, it is true that in a large proportion of cases of melancholia developing late in life, high arterial tension has been present. The author has obtained the best therapeutic results in such cases by endeavoring to strengthen the heart and to relieve the obstruction in the capillary system. The more acute the attack, the better the prospects of recovery.

Melancholia associated with extremely low tension usually proves incurable. The author reports the only case which he has ever seen recover.

As associated with the cerebral affection he says that, in the slowly developing par-

aplegia due to failing circulation, the lumbar enlargement of the cord does not receive sufficient blood, owing to the anatomical arrangement of the blood-supply. The symptoms are first noticed only after a night's rest, and pass away as the day goes on. He has seen this condition develop when the circulation was made sluggish either by very low tension or by high tension with an overtaxed heart.

THE RECOGNITION OF DILATATION OF THE RIGHT AURICLE.

Schrötter (*Medizinische Jahrbücher*, 1887, H. 1, 51) places this condition among the diseases of the thoracic viscera whose diagnosis is attended with great difficulty, and reports a most interesting case. The patient, a girl of 24 years, suffered with cyanosis, palpitation, dyspnœa, ascites, and œdema. The dilated cervical veins were distinctly and constantly pulsating. The apex-beat could be faintly felt in the sixth interspace outside the nipple-line. The cardiac percussion-dulness was normal on the left side, but stretched also to the right of the sternum, and was of a very peculiar shape. On this side good pulmonary resonance extended downward in the nipple-line to the sixth rib; one and one-half centimetres inside this it reached to the fourth rib; one and one-half centimetres still nearer the sternum it only touched the lower edge of the third, and close to the right sternal edge it reached the middle of the fourth rib. This area of dulness was more prominent than the corresponding region on the left side. The pulmonary second sound was accentuated. A double murmur was heard at the apex, and, with less strength, over the right ventricle. The pulse was weak and small. A few râles were heard in the lungs, especially on the right side below and behind. The liver was enlarged, and the spleen slightly so.

A diagnosis was made of insufficiency and stenosis of the mitral valve, together with insufficiency of the tricuspid. But the peculiar form of the percussion-dulness remained still to be explained. It was evidently not a simple enlargement of the heart in all directions, and the shape of the dulness contra-indicated pericardial effusion. The presence of aneurism of the aorta or of a mediastinal tumor was not supported by other symptoms. The diagnosis then lay between an encysted pleurisy, a pericardial effusion limited by adhesions to the right side of the heart, and a hugely dilated right ventricle. The presence of valvular disease indicated the last of these, but the fact that the area of dulness was not diminished during inspiration seemed to point to the first. The diagnosis of dilatation of the right ventricle was finally established by means of the hypodermic syringe. The needle was inserted and found to make swinging movements in time with the heart's action, and pure blood was obtained. No evil result followed, but the patient died some weeks afterwards. The autopsy confirmed the diagnosis throughout. There was found in addition a stenosis of the tricuspid valve and a retraction and contraction of the right lung, which was adherent to the pleura. This condition allowed the right ventricle to approach so closely to the chest-wall.

ON THE PATHOLOGICAL INDICATIONS OF VENOUS MURMURS IN ANÆMIC CONDITIONS.

In *Virchow's Archiv*, B. cvii. H. 3, 419, there appears an article on this subject by Apetz, who says that up to the elaborate work of Weil in 1875 very various opinions had been held regarding the significance of the venous hum in the jugulars. This author proved, as the result of observations on six hundred persons, that the phenomenon had no connection with any particular form of disease. Many later authors have not accepted this view. Gerhardt believes anæmia has a decided influence on the production of venous murmurs, and Guttmann, who has sought it in hundreds of cases, finds it far more frequently in anæmic persons. Induced by the variance of opinions, Apetz has auscultated the internal jugular veins of six hundred and sixty persons, including one hundred and fifteen markedly anæmic individuals. After a careful study of the relation of age and of the degree of anæmia to the presence of the venous murmur, he concludes that—

1. The occurrence of a murmur in the internal jugular is chiefly dependent upon age: the older the person, the less frequently is the murmur found.

2. Venous murmurs which become audible only on turning the head to the opposite side are physiological, and have no connection with anæmia.

3. Those heard when the head is straight

and the patient in the upright position, and from twenty to sixty years of age, have a certain pathological significance if they are loud and constantly present. Yet they are usually not sufficiently pronounced to be of value in the diagnosis of anæmia.

4. In general, venous murmurs possess no diagnostic value for chlorosis or other anæmic conditions.

OVERDISTENTION OF THE RIGHT VENTRICLE TREATED BY LEECHES.

F. C. Shattuck (*Boston Medical and Surgical Journal*, 1887, No. 17, 395) says the tendency of any block to the circulation is to produce an overdistention of the venous system. If the obstruction is in the arteries, the heart may be strong enough to overcome it; but when the left ventricle gives out, or when the trouble is at the mitral valve, the strain is thrown upon the right ventricle, which thereupon so often becomes incompetent. We then find all the symptoms of general, intense passive congestion developing. Our effort in such cases must be to relieve the engorgement by increasing the heart's power. Often this is impossible without an actual removal of fluid. Catharsis may then be employed, but is very exhausting; and, moreover, it frequently cannot be induced. The author advises in many grave cases the direct abstraction of blood, preferably by leeches followed by poulticing, since the removal of eight to ten ounces will often give surprising relief, and will afford the overburdened heart a chance to regain its power. He reports six cases, in five of which an amelioration of the threatening symptoms promptly followed the leeching. In the remaining case probably not enough blood was taken. He does not believe that two of his cases would have lived more than a few days if he had not drawn blood.

TRANSLATIONS.

GLUCOSE, GLYCOGEN, AND GLYCOGENY.—At a recent meeting of the Academy of Sciences, M. Chauveau presented a note entitled "Glucose, Glycogen, and Glycogeny in Relation to the Production of Heat and of Mechanical Labor in the Animal Economy." M. Chauveau believes himself to be in a position to affirm the preponderating part played by the glucose of the blood in organic combustion, which is the source of heat and of muscular action. The liver is, in truth, as Claude Bernard affirmed, a focus of incessant production of sugar, and by the side of the focus there exists another for its destruction which is quite as active. But the latter is not in the lungs; it is everywhere in the body, having its seat in the capillaries of the general circulation. The author bases his conclusions on the following results of his own experiments:

1. In fasting animals sugar exists in the blood of the arteries and veins of the circulatory system; but in the upper hepatic vessels the blood is richer in sugar than anywhere else, even when it has been obtained without arrest of the circulation, thus avoiding the causes of error arising from the stagnation of the blood in the liver: this organ then is really a sugar-producer.

2. This relative richness of glucose in the blood is observed in the upper hepatic veins not only in fasting animals, but also in animals that have been submitted to a prolonged fast, continued almost to the verge of inanition, when the sugar derived from the former nutriment and provisionally stored in the liver in the form of glycogen has long since been exhausted. From which it must be inferred that the liver may generate sugar spontaneously, and is thus a focus of active production.

3. The blood of the left heart contains as much sugar as that of the right heart, which is an evident demonstration of the non-destruction of the sugar during the passage of the blood through the lungs in the vessels of the lesser circulation.

4. In the vessels of the general circulation the venous blood contains less sugar than the arterial blood, which shows that the capillaries of the general circulation are really a focus for the destruction of sugar.

The author terminates with the following observation: In comparing the blood of organs whose heat-producing activity in the physiological state is very unequal, it is always observed that the incessant destruction of glucose is much more active in that organ where organic combustion is greatest; in other words, the quantity of heat produced in the animal tissues, which is always proportional to the intensity of the combustion, is likewise proportional to the absorption of the glucose of the blood in the capillary system.

EDITORIAL.

MALARIA, AND AMERICAN SCIENTIFIC OBSERVATION.

IN his voluminous work on General Pathology, just issued from the press, Professor Klebs argues in a despairing sort of way in favor of the pathogenic importance of the bacillus malariæ discovered by himself and Tommasi-Crudeli in 1879. No notice is taken of the critical investigations of Sternberg in 1880, or of the more recent observations of Councilman and Abbott in 1884, and of Sternberg, Councilman, and Osler in 1886, which seem to negative the "discovery" of Klebs. Marchiafava and Celli, who described the plasmodium malariæ in 1883, and Laveran, who discovered the flagellate organisms (oscillaria malariæ), which he regards as the cause of malarial fevers, receive scant courtesy at his hands. Klebs does not only doubt the pathogenic nature of the plasmodium of Marchiafava and Celli, but even raises a question whether it is an organism at all. He intimates that "the apparent contractions" of these bodies may be due to contractions of the red contents of the blood-corpuscles. In view of the extensive observations of Councilman and Osler upon malarial blood, this opinion of the Zurich pathologist savors somewhat of undue arrogance. Regarding the development of the organism which is the cause of malarial fevers,—of course the bacillus malariæ,—Klebs believes that this takes place only in soil of medium moisture in which there is vegetable decomposition. Saturation, as well as complete drying out of the soil, prevents the development of the malarial organism. He denies that malaria is transmitted in drinking-water, contradicting in this assertion the experience and observation of Dr. Charles Smart, of the United States Army, of whom Professor Klebs appears likewise never to have heard. In fact, throughout his book, which is devoted entirely to the causes of disease, American investigators and observers are deliberately ignored. Whether this is due to ignorance of their work or to an arrogant assumption that it is worthless, the omission of all reference to it is discreditable to the Zurich professor. In the chapters on yellow fever, typhoid fever, diphtheria, and pneumonia, the same systematic suppression of the names of American scientists is practised. The names of Flint, Jacobi, Sternberg, Wood, Woodward, and many others who have contributed so much to the general fund of knowledge upon the etiology of infectious diseases, are conspicuous by their absence.

We are sure that no American author of standing would be guilty of such a lack of scientific courtesy as Professor Klebs has manifested in the pages of his work. American bacteriologists have for some years labored honestly and to good purpose in the field of pathology. If Professor Klebs is ignorant of the work done here, he is hardly competent to act as a safe guide to the modern student. If, on the other hand, he is familiar with American pathological research, his omission of all reference to it is worse than a confession of ignorance. His choice lies between the two horns of this dilemma.

HOT WEATHER HYGIENE.

A GREAT increase in the death-rate of our large cities has been noticed during the recent spell of hot weather. A temperature of a hundred degrees in the shade means a corresponding rise in the death-rate. Besides the mortality directly attributable to heat-stroke, the lethal influence of the excessive temperature is

shown by the number of deaths among individuals of feeble vitality, both young and old. Everything in life is relative, and a day that would be considered only moderately warm in the tropics is intolerable in Philadelphia or New York. Although we do not experience a temperature in this latitude of, say one hundred and twenty degrees in the shade, yet our habits of life make the even hundred quite as fatal in its effects. During the heated term it would be well to borrow the results of experience of travellers in hot countries. Parkes has demonstrated that soldiers can march better without a spirit ration than with; and Stanley considers it fatal even to use light malt-liquors or wines in equatorial Africa. The clothing should be adapted to the weather, light flannel being the most comfortable and wholesome. Exercise should be restricted, and work suspended during the middle of the day. Alcoholic drinks being excluded, ice-water and cold drinks may be sipped, but not drunk in excess. Large quantities of cold drinks not only cause gastric catarrh, and consequently impaired digestion, but also may cause death from shock. Such a case occurred in this city recently from drinking ice-water while overheated. A tropical diet of rice and fruits would be a good substitute for our usual heavier food, especially in the dietary of children. Crowd-poison seems to be especially developed in cities during hot weather, and hence the exodus to sea-shore and mountain has in its support both physic and fashion. The ancient temples of Æsculapius were always placed in the most salubrious localities, near healing springs, and not without reason:

"The murmur of a waterfall
A mile away,
The rustle when a robin lights
Upon a spray,
The lapping of a lowland stream
On dipping boughs,
The sounds of grazing from a herd
Of gentle cows,
The echo from a wooded hill
Of cuckoo's call,
The quiver through the meadow grass
At evening fall,—
Too subtle are these harmonies,
For pen or rule.
Such music is not understood
By any school;
But when the brain is overwrought,
It hath a spell,
Beyond all human skill and power,
To make it well."

MEDICAL SOCIETIES.

THE ability to take a prolonged summer vacation is not enjoyed by the mass of the profession, and is restricted to a select circle largely composed of those physicians whose peculiar and lucrative specialty enables them to devote a few months each year to "leading the fashion in the upper Engadine." Nevertheless, the advice of Sir Henry Holland is not unheeded. The proverb older than Æsop with regard to the bow that is always bent has its truth generally admitted, but, unfortunately, those who are most useful to their fellow-men find that their services are so constantly in demand that an opportunity even to temporarily lay aside their duties rarely appears. The meetings of the various medical societies, with their attractive social features, afford an illustration of the correspondence of duty and inclination which is hard to resist. Even a week's holiday spent in attending the annual session of the American Medical Association gives rest and recreation and fresh inspiration for the daily round of work. But a man who belongs to a number of societies may find himself so embarrassed with the riches that are offered him that he either cannot make up his mind which to attend, and so remains at home, or he may, in attempting to attend all, find his time so restricted as practically to deprive him of the real benefit of any. This is one of the evil results of the undue multiplication of societies.

COMMUNICATIONS FOR THE CONGRESS.

AMONG the meetings of the year the most noteworthy will be that of the International Medical Congress in Washington next September. To this every regular physician is entitled to come and enroll himself as a member and participate in all the proceedings. Such an opportunity to meet men whose reputation is world wide, and to listen to their voices, will surely be embraced by large numbers of the profession. As the programme will soon be completed for the Congress, all who expect to read papers should send a synopsis of their communications to the secretary of the appropriate Section without delay, or they may find themselves too late, especially since nearly every one who attends from abroad will probably bring a paper with him.

NOTES FROM SPECIAL CORRESPONDENTS.

LONDON.

THE JUBILEE CELEBRATION—JUBILEE HONORS FOR THE MEDICAL PROFESSION—RECENT RESEARCHES INTO THE ETIOLOGY OF SCARLET FEVER—THE EPIDEMIC OF RABIES—THE MEETING OF THE BRITISH MEDICAL ASSOCIATION IN DUBLIN—THE HEALTH OF THE CROWN PRINCE—SIEGESBECKIA IN TINEA—HOSPITAL SUNDAY.

THE celebration of the Jubilee of the Queen's reign has filled everybody's mind during the last fortnight, and nobody who saw London on June 21 will ever forget the spectacle then presented. It was less the procession itself, remarkable though that was, than the crowds which thronged the route which gave the occasion its peculiar and memorable character. The excellent behavior of the people is shown by the very small number of casualties. At a low estimate there must have been over a million people in the streets, yet not half a dozen people were seriously injured. One man, kicked in the chest by a trooper's horse, died in a few minutes, and it was found at the post-mortem examination that the manubrium sterni had been fractured, the pericardium torn, and the left ventricle ruptured at a point corresponding to the fracture in the sternum; another man fell off a coping and sustained a fracture of the base of the skull, from which he shortly died; another man suffered fracture of the femur, and seventeen persons had heat-stroke. The Volunteer Medical Staff Corps was out, under Surgeon-Major Norton, and assisted Mr. Mackellar, chief surgeon of the police, in manning the thirteen ambulance-stations established along the line of route. The assistance given was prompt and effective, but most of the patients were suffering with slight syncope or hysteria. At one ambulance-station a man who became faint was given a dose of brandy and allowed to sit in the ambulance-wagon. In a few minutes a regular epidemic of syncope set in, and the surgeons in charge had to make the differential diagnosis between syncope and malingering in a whole series of individuals whose envy had been excited by the sight of the dose of brandy and the shady and elevated seat.

The "Gazette" issued on Jubilee-Day was not a very interesting document to any class in the community. The medical profession came off no worse than others. Dr. Garrod, whose writings on gout have made his name familiar, received a knighthood; so did Professor MacLeod, the eminent Glasgow surgeon, and Dr. Aitken, long Professor at the Army Medical School at Netley, and author of a "Systematic Practice of Medicine" once very widely used in this country. Mr. John Simon, who, when he retired from the direction of the medical department of the sanitary service of the country, was made a C.B., now becomes Sir John Simon, K.C.B., and Dr. Arthur Mitchell, a Commissioner in Lunacy in Scotland, also receives the K.C.B. Dr. Ker Innes, of the medical staff of the army, Dr. William Mackenzie, of the Indian Medical Service, and Dr. James Jenkins, of the Royal Navy, are the recipients of the same distinction. Dr. J. A. Grant, of Ottawa, Canada, becomes a Knight-Commander of the Order of St. Michael and St. George (K.C.M.G.). These are all the important distinctions conferred. No peer, no Privy Councillor, not even a baronet!

In previous letters reference has been made to the researches conducted by Mr. W. H. Power and Dr. Klein, for the Local Government Board, into the supposed connection between scarlet fever and milk. Mr. Power traced an epidemic of scarlet fever to the milk obtained from a particular dairy near Hendon. The cows were found to have been suffering with a disease the local lesion of which was a vesicular eruption on the udders, ending in ulceration. Dr. Klein found that the disease could be produced in calves by inoculation of the discharges; he found a streptococcus in the discharges of the ulcers, and the same organism in the blood of cows suffering with the disease; inoculation with pure cultivations of the streptococcus pro-

duced a disease in calves which, in Dr. Klein's opinion, resembled human scarlet fever. The same streptococcus was found in the blood of human beings suffering with scarlet fever. As has been observed in a previous letter, the proof that the streptococcus is the virus of the vesicular disorder of cows appears to be pretty conclusive. The conclusion that it is also the virus of scarlet fever rests upon the three following observations: (1) the coincidence of the epizoötic in the dairy cows with the epidemic of scarlet fever; (2) the resemblance between the pathological appearances produced in the kidneys and skin (?) in calves by inoculation with the virus of the epizoötic to the lesions of scarlet fever; and (3) the discovery of the same organism in the blood of the calves and of persons suffering with scarlet fever. It ought to be added that Dr. Klein found the same streptococcus in some tinned milk to the use of which an epidemic of scarlet fever had been traced by Dr. Klein. Objections to Dr. Klein's theory must follow one of two lines: (1) It may be contended that the epidemic had nothing to do with the state of health of the dairy cows, but is to be attributed to contamination of the milk from some unrecognized local source; or (2) it may be held that the epidemic was due to some epizoötic disease of the cow, but not to the particular vesicular disease identified by Dr. Klein. The first objection is that maintained by the veterinary authorities, headed by Professors Brown and Axe, who say that the vesicular disease of the udders is well known to veterinary surgeons and extremely common in dairy-farms, whereas scarlet fever has never before been traced to the milk-supply. Professor Axe believes that he has ascertained that the cows which introduced the disease into the Hendon dairy came from a dairy from which a number of other cows were sold to go to dairy-farms in other parts of the country without any corresponding outbreaks of scarlet fever following in those localities. The second objection has been raised by a research conducted by Mr. Edington for Professor Chiene and Dr. Jamieson, of Edinburgh. This research, which was published in the *British Medical Journal*, was undertaken with the view of testing the specific infectivity of the desquamation of scarlet fever. Two organisms especially attracted attention: one was a diplococcus (to which the name *diplococcus scarlatinæ sanguinis* was provisionally applied); it was found in forty-five per cent. of the tubes inoculated from the desquamation, and in thirty per cent. of those inoculated with the blood of cases of scarlet fever; the other was a bacillus (to which the term *bacillus scarlatinæ* was provisionally applied). It occurred in every tube inoculated with the desquamation after the termination of the third week, and in every tube inoculated with blood taken before the third day of the fever. Inoculation of the diplococcus gave negative results. The bacillus, inoculated into rabbits and guinea-pigs, produced fever with local erythema followed by desquamation. In a calf, inoculation was followed by vomiting and pyrexia, and by death in a few hours. It is a pity that Dr. Edington did not inoculate a calf with blood from a case of scarlet fever, in order to compare the result with those obtained from the inoculation of his bacillus, of Dr. Klein's streptococcus, and of the Hendon udder-ulcers. At present the only safe course is to reserve judgment on the main question, while acknowledging that Dr. Edington has made an important contribution to our knowledge of the pathology of scarlet fever.

The epidemic of rabies and hydrophobia which commenced in the spring of 1885 seems to have come to an end, so far as London is concerned, in the early autumn of 1886. No case of hydrophobia was returned in London from September, 1886, to April, 1887, both inclusive. One death occurred in May last; but there is no reason to suppose that another epidemic is commencing, although the police regulations have been relaxed in London. In other parts of the country, where cases of rabies have been increasing in number, it has been necessary to make the regulations more stringent. It is one of the disadvantages of the Anglo-Saxon love of decentralization that local authorities alone have the right of enforcing orders of this nature, and that it is practically impossible to get any considerable number to act in concert. It thus happens that, while we are stamping out rabies in London, it is allowed to increase in the North, and *vice versa*. The London epidemic of hydrophobia reached its maximum in October and November, 1885; the stringent police order came into force early in November; all dogs were required to be muzzled or kept under control, and ownerless dogs were condemned to death. An enormous number of stray curs were taken to the Home for Lost Dogs, and there put to a painless death.

The immediate effect of the police order was not very marked. There was, it is true, a sudden drop in the number of cases in December; but, remembering the incubation-period of hydrophobia is at least six weeks, it would not be safe to attribute the decline to the order, the more as three deaths occurred in January, and three more in March. During the spring and early summer months the average is generally low, and it is not until we look at the returns for the last five months of 1886 that we can recognize that the epidemic had been extinguished. Altogether, thirty-five persons had died of the disease during the epidemic, and of these, eighteen, or more than half, succumbed during the last five months of 1885; while during the same portion of 1886 not a single death from the

disease occurred. This is the more remarkable as September, October, and November are believed to be the months of greatest prevalence of hydrophobia in this country.

Table showing the Number of Deaths in each Month from Hydrophobia during the Epidemic of 1885–1886. (*London only.*)

	1885.	1886.	1887
January	1	3	0
February	0	0	0
March	0	3	0
April	3	1	0
May	2	0	1
June	1	0

August	3	2	
September	4	0	
October	5	0	
November	5	0	
December	1	0	

The report of the commission appointed to investigate M. Pasteur's method will be presented to Parliament on June 27. It is understood to be very favorable to his claims.

The arrangements for the meeting of the British Medical Association in Dublin on August 2, 3, 4, and 5 are now nearly complete. The address by the President, Dr. John T. Banks, Regius Professor of Physic in the University of Dublin, will be delivered on the afternoon of the first day; but previously members will have had the opportunity of listening to two sermons: one in the morning, in the Catholic Pro-Cathedral, by the Rev. Martial Klein, once a surgeon in the French army, but now a member of the Society of Jesus and Professor of Biology in University College, Dublin; the other in the afternoon, by the Bishop of Meath, an eloquent and learned prelate of the Protestant Church of Ireland. The chief discussion in the Section of Medicine will be on "Aphasia," introduced by Dr. Charlton Bastian, F.R.S., the most profound and original of modern writers on that most interesting topic. The Section of Surgery will discuss the "Radical Cure of Hernia," and already four papers and fourteen speeches are promised on that subject alone. Dr. Playfair will introduce the question of the "Prevention of Puerperal Fever" to the Obstetric Section, and Dr. Halliday Croom that of "Displacements of the Uterus," two topics generally provocative of much discussion. The special subject in the Section of Pharmacology and Therapeutics is the "Therapeutics of the Uric-Acid Diathesis." No less than eighteen surgeons, including Dr. Argyll Robertson and Mr. Nettleship, have signified their intention of discussing the subject of the "Etiology and Treatment of Convergent Concomitant Strabismus," which will be introduced to the Ophthalmological Section by Mr. Simeon Snell, of Sheffield. Dr. Landolt, of Paris, and Dr. Uhthoff, of Berlin, are coming over to read papers in this Section. Dr. Apostoli, of Paris, has promised to read a paper on the "Electric Treatment of Fibroid Tumors of the Uterus," giving full statistics of all the cases treated from July, 1882, to July, 1887; Dr. Kocher, of Berne, will read a paper on "Cachexia Strumipriva and Myxœdema;" Sir Spencer Wells will compare Porro's operation with Cæsarean Section; and Dr. Benjamin Ward Richardson will discourse of his favorite subject, "Alcoholism." There will thus be no lack of subjects of the greatest scientific and practical importance for discussion. There will also be more than the usual list of social festivities. The University of Dublin has offered every facility to the Association, and, in connection with the meeting, it intends to confer the honorary degree of M.D. on Professor Gairdner, of Glasgow, who delivers the Address in Medicine; on Dr. Waters, of Chester, who has been so long identified with the political activity of the Association; on Sir James Paget, Sir Spencer Wells, and Sir John Semon. Prince Albert Victor (the eldest son of the Prince of Wales) and the Lord-Lieutenant are to receive honorary degrees on the same day.

Dr. Morell Mackenzie has succeeded in removing the greater part of the growth which has interfered with the health of the Crown Prince of Germany. Professor Virchow has, after careful examination of the fragments, declared the affection to be *pachydermia verrucosa*, and non-malignant. It has required, however, all his authority to silence the objections of those who maintained that the tumor was cancerous and advised the removal of half the larynx. The Crown Prince is now staying in an hotel at Norwood, close to the Crystal Palace, a locality which has a great reputation, probably quite undeserved, for its salubrious climate. He is seen frequently by Dr. Morell Mackenzie, and Dr. Norris Wolfenden has gone to live at Norwood in order to carry out Dr. Mackenzie's treatment. He has the intention to attempt the removal of the small remainder of the growth at an early date. The Prince is quite hoarse, but otherwise in good health.

Dr. J. Hutchison, of Glasgow, has been using a tincture of Siegesbeckia orientalis in ringworm with success. The plant belongs to the natural order Compositæ, and has a local reputation in the Mauritius as a cure for all the ills that flesh is heir to. The rest of the world will perhaps be content if other observers find it as efficacious against tinea circinata, tinea tonsurans, and tinea sycosis.

June 19 was Hospital Sunday in London this year. The amount collected is not yet known, but, so far as at present appears, the total is not likely to be unusually large. For the last two years special public meetings have been held in various parts of London in the week preceding Hospital Sunday, in order

to arouse greater public interest in the fund. The managers of the hospitals situated in each locality have been asked this year to arrange for these meetings, and to ask the friends of each hospital to take part in the proceedings. This request has not met with unanimous compliance: certain hospitals have refused point-blank to help, and others were lukewarm. The honorary secretaries of the fund thought fit to denounce these hospitals at a meeting, and made use of threats which were interpreted to mean that the sum voted to these recalcitrant institutions would be diminished or entirely stopped. Sir Sydney Waterlow, the chairman of the committee of distribution, after a rather acrimonious correspondence had gone on for more than a week in *The Times*, repudiated the threat, but the mischief has been done. Mr. John Biddulph Martin, chairman of the Economic Section of the British Association, and the treasurer of Charing Cross Hospital, has printed a memorandum stating the reasons which have led the hospitals to decline to assist in getting up the local meetings. Shortly stated, there are two,—namely, that to do so would interfere with the established rule of these hospitals to make special efforts to enlist the special sympathy and support of persons resident in their own localities, and that the Hospital Sunday Fund was started to add to the resources of the hospitals by tapping new sources of supply, and not to cut into the existing sources of revenue. Perhaps there is yet a stronger reason, for injudicious friends of Hospital Sunday Fund have maintained that we want a central board controlling the finances and administration of all hospitals. Such centralizing proposals, as I have remarked elsewhere in this letter, are always detested in this country. *Hinc illæ lachrymæ.*

The creation of a studentship in pathology, under the provisions of the trust fund left by the late Mr. John Lucas Walker, is the first instance of the endowment of pathological research. The first "student," Dr. William Hunter, of Edinburgh, has just been named, and Cambridge may be congratulated on having found so promising a pathologist, or, as the late Dr. Walter Moxen would have had us say, "pathonomist," for the first holder of the studentship.

Fifteen new Fellows of the Royal Society were elected on June 9. Four are members of the medical profession, but only two of these owe this crowning distinction to their medical achievements. These are Dr. J. Theodore Cash, recently appointed professor of therapeutics in the University of Aberdeen, and Dr. W. R. Gowers, the well-known neurologist. The others are Surgeon Major George King, known as an Indian botanist, and Sir John Kirk, K.C.M.G., of Zanzibar, the friend of Livingston and many other African explorers. DAWSON WILLIAMS.

PROCEEDINGS OF SOCIETIES.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

THE Thirty-Eighth Session of the Medical Society of the State of Pennsylvania was held at Bedford Springs, June 29 and 30, and July 1, 1887. About two hundred delegates and permanent members were present.

The Society was called to order by the President, R. Davis, M.D., of Wilkesbarre, at 9 A.M., June 29, and the proceedings were formally opened by the Rev. E. N. Kremer with prayer.

The address of welcome was delivered by S. H. Gump, M.D., Chairman of the Committee on Arrangements. The programme presented by the committee was approved and adopted.

Dr. Edward Jackson, Chairman of Committee on Medical Legislation, reported progress. The bill read at the last meeting of the Society had failed to pass the Legislature, and for the present nothing more can be done, but correspondence had been kept up with the county medical societies, many of which had agreed to appoint a committee to agitate the subject and advance public opinion upon the propriety of having such a law. In conclusion, he submitted a formal resolution requesting each county medical society to consider the subject of establishing a State board of examiners, and to appoint a committee to co-operate with the State Medical Society. This was adopted.

The report of the Publication Committee was criticised. The resolution offered at the last meeting by Dr. Packard restricting the publication of scientfic papers to their titles in the Proceedings was not adopted, but a resolution prevailed to exclude unnecessary matter from the annual volume.

The resolution offered at the last meeting by Dr. W. H. Parish dividing the scientific work of the meeting so that the surgical, medical, and obstetrical addresses and communications should occupy in rotation the three days of the session, each day to be devoted to one of these three branches of medicine, was carried after considerable discussion. [This resolution was reconsidered and lost on the last day of the session. It was resolved that the Addresses in Medicine, Surgery, and Obstetrics should be delivered in rotation at successive meetings, and that the Address in Hygiene be given a place early in the session.]

In the afternoon session a number of interesting papers were presented. J. B. Murdoch, of Pittsburg, delivered the Address in Surgery. Among recent advances in this department made possible by improvements in treating wounds, the operation of amputation through the foot, known as Chopart's operation, deserves special consideration. By this method sufficient material is saved to

give a useful foot. The lecturer reported a case in which this operation was performed on both feet, and the patient was afterwards able to walk erect with only one cane, and even for a short distance without any assistance or support. Plaster casts were exhibited showing the successful result of this operation.

The Address in Ophthalmology was delivered by Charles S. Turnbull, M.D., of Philadelphia. Charles W. Dulles, M.D., of Philadelphia, read a report on hydrophobia for 1886, in which he criticised the Pasteurian method of treatment on account of its empirical and unscientific character. Until the pathology of the various conditions accompanied by so-called hydrophobic symptoms is more clearly understood, the foundation for a really scientific therapeutics cannot be laid.

John V. Shoemaker read a paper advocating the "Use of Medicated Plasters in the Treatment of Diseases of the Skin," and exhibited some pharmaceutical preparations of this character.

An interesting specimen of a testicle removed from the right labium majus of a married woman (transverse hermaphrodite), aged 40 years, was demonstrated by Howard A. Kelly, M.D., of Philadelphia.

In the evening the Society, as the guest of the Bedford County Medical Society, enjoyed a reception and banquet at the Bedford Springs Hotel, at which numerous short addresses were made.

On the second day the proceedings were opened by prayer, and the Address in Medicine was delivered by Frank Woodbury, M.D.* Traill Green, M.D., of Easton, read a paper on "Palatable Therapeutics," in which he contrasted prescriptions and methods of fifty years ago with those in vogue to-day. He praised very highly modern pharmacy, which has given us alkaloids and pleasant medicines in place of the nauseating compounds formerly used, and he declared that at the present time diseases are treated in a much milder way than in the days of heroic dosing. He did not think that a physician need resort to any unpalatable remedy in order to treat disease successfully.

This paper gave rise to an animated discussion. Professor Remington, of the Philadelphia College of Pharmacy, spoke of the administration of quinine suspended in the syrup or elixir of glycyrrhizin, and advised that no acid should be added in writing the prescription. The quinine should not be dissolved, but merely suspended in the mixture, or it may be added in powder to the solution of glycyrrhizin at the time of administering the remedy.

George Stubbs, M.D., of Philadelphia, read a paper on "Iodoform in Surgery," advocating the use of a chemically pure iodoform as a perfectly antiseptic dressing for wounds.

Papers on the treatment of phthisis by new methods were read by William F. Waugh, M.D.,† S. Solis Cohen, M.D., and Thomas J. Mays, M.D., in which the first opposed the Bergeon method, and the latter two gave it a qualified endorsement, not as a bactericidal treatment, but as a means of relieving some of the symptoms.

John H. Packard, M.D., of Philadelphia, reported a case of stricture, probably malignant, of the colon, for which he successfully performed right inguinal colotomy, after the usual operation in the left loin had failed to reveal the colon. The patient is now living; all the fæces are discharged through the artificial anus, but there is no offensive odor about her person, so that her condition would not be suspected by those around her.

In the afternoon, Dr. S. Wolfe, of Skippack, Pennsylvania, read the Address in Obstetrics, advocating antiseptic precautions during labor, and the use of washes after confinement as a means of preventing or treating puerperal septicæmia.

This paper was discussed by Drs. Montgomery, Parish, and others.

William C. Bane, M.D., of Washington County, read a paper describing two cases of nystagmus associated with astigmatism, one myopic and the other hypermetropic. Great improvement was observed after properly correcting the errors of refraction.

Edward Jackson, M.D., read a paper entitled, "When and How to use Mydriatics."

The Annual Address of the President (see page 685) was delivered at the evening session, according to custom.

At the opening of the third day's morning session, Dr. J. D. Thomas, of Pittsburg, read the Address in Hygiene, in which the necessity of disinfecting discharges from cases of all zymotic diseases was insisted upon. The methods of disposal of sewage were considered at length, and the importance of a system by well-laid sewers in all large communities was emphasized. A vigorous discussion following this address showed the increasing interest of the profession in sanitary subjects.

The following papers were read by title only: Remarks on the Value of Diet in the Treatment of Chronic Joint- and Spine-Disease, by A. Sidney Roberts, M.D., of Philadelphia; Plastic Surgery of the Vagina, by C. M. Wilson, M.D., of Philadelphia; Address in Mental Disorders, by J. Z. Gerhard, M.D., of Harrisburg; A Case of Ovariotomy followed by Herniotomy four days after, with Recovery of Patient, by John C. Da Costa, M.D., of Philadelphia; Some Considerations upon the Use of Expectorants in Pulmonary Diseases, by J. C. Lange, M.D., of Pittsburg; Ovarian Tumors complicating Pregnancy,‡ by E. E. Montgomery, M.D., of Philadelphia; Supra-Pubic Lithotomy, by Charles W. Dulles,

* This will appear in the next issue of the *Times*.

† Dr. Waugh's paper will shortly appear in these pages.

‡ See page 693, *ante*.

M.D., of Philadelphia; Remarks on Vomiting, Physiological and Clinical, by J. H. Musser, M.D., of Philadelphia.

In the business meeting the Society voted an appropriation of one thousand dollars to the Entertainment Committee of the Ninth International Congress, and three hundred dollars (one hundred annually for three years) to the Rush Monument Fund.

The following officers were elected for the next meeting:

President.—R. J. Levis, M.D., Philadelphia.

Vice-Presidents.—J. T. Ullom, M.D., Greene County; J. L. Seybert, M.D., Centre County; W. F. Hughes, M.D., Bedford County; A. M. Cooper, M.D., Bucks County.

Permanent Secretary.—William B. Atkinson, M.D., Philadelphia.

Recording Secretary.—Charles W. Dulles, M.D., Philadelphia.

Corresponding Secretary.—J. H. Musser, M.D., Philadelphia.

Treasurer.—O. H. Allis, M.D., Philadelphia.

Chairman of Committee on Publication.—W. H. Parish, M.D., Philadelphia.

The next meeting will be held in Philadelphia on the first Tuesday in June, 1888. Dr. John H. Packard is Chairman of the Committee on Arrangements.

THE AMERICAN LARYNGOLOGICAL ASSOCIATION.

MEETING OF MAY 26, 27, and 28, 1887.

(Continued from page 682.)

Third Day, Morning Session.

CONSTITUTIONAL CAUSES OF THROAT-AFFECTIONS. BY S. W. LANGMAID, M.D., OF BOSTON.

THE writer suggested that the most interesting lesson to be drawn from the observation of the lesions in throat-trouble is that there is some underlying cause, which may be external or intrinsic. Our attention has been directed too much to the local condition and to atmospheric influences. Why atmospheric conditions are active at one time and not at another is a matter worthy of consideration. One of the most intractable diseases which we have to treat is chronic recurring coryza. Sometimes destruction of the mucous membrane of the nose is sufficient; but, as a rule, the treatment must take in all the circumstances of the life of the sufferer. A sense of a lump in the throat, so often complained of, is often an indication of an overloaded colon, and more good is done by a dose of castor oil than by local treatment. The so-called clergyman's sore throat, or follicular laryngitis, has its origin not in the necessary use of the throat, but the sedentary life, with errors in diet and other conditions, plays an important part. Throat-trouble is sometimes a rheumatic or gouty manifestation, and treatment has to be directed to this condition. Local treatment in many throat-troubles is of the nature of repair; constitutional and hygienic treatment must be in the direction of a renewal of the normal processes. Swelling and congestion of the mucous membrane, hypertrophy of the tonsil, elongation of the uvula, etc., must be regarded as symptoms, and the symptoms will not be banished unless the underlying constitutional abnormality be removed.

In the discussion, Drs. Glasgow and Cohen agreed with the reader of the paper.

Dr. Delavan said that in this country we pay too little attention to the hygienic surroundings which are employed at the various spas abroad. This method of treatment is very beneficial in cases of interference with the portal circulation and in gouty diathesis. He had found the salicylates of great service in some of these cases of throat-trouble. Habitual constipation usually accompanies chronic disease of the pharynx. I have used in these cases the officinal pill of iron and aloes, directing that one be taken at night.

The following papers were read by title:

"Affections of the Crico-Arytenoid Articulation," by George W. Major, M.D., of Montreal.

"Cancer of the Larynx," by Hosmer A. Johnson, M.D., of Chicago.

"A Case of Recurring Laryngitis Hemorrhagica," by C. E. Bean, M.D., of St. Paul.

The report of

A CASE OF STENOSIS OF THE LARYNX TREATED BY DIVULSION AND SYSTEMATIC DILATATION

was contributed by Morris J. Asch, M.D., of New York.

Miss K. enjoyed good health up to about the age of 27. She then had some pulmonary disorder the exact nature of which could not be ascertained. In 1884 she had some wheezing in breathing, with slight cough. These symptoms increased in intensity gradually, and in May, 1885, the patient came under the observation of the author. There was at this time great dyspnœa, which was increased by lying down. Examination of the throat showed no abnormality in the larynx or above the cords. Below the cords there were two white swellings united by a membrane posteriorly. The opening of the larynx was diminished to one-third of the normal size. The membrane was cut and divulsion performed. This caused great improvement. Later metallic sounds were used daily, and the forceps once a week. She grew much better, and ceased attending. In September she again returned, with the difficulty of breathing as great as before. This was the result of acute inflammation of the larynx. Under

the use of steam and cold compresses the swelling subsided. O'Dwyer's tubes were tried, but they at once produced spasm and were coughed out. Schroeder's hard-rubber tubes were then used, and within three months the cure was perfect. All the symptoms have now disappeared. There was no history of syphilis and no history of previous inflammation. The affection was evidently the result of subcordal hypertrophic laryngitis.

Dr. J. Solis Cohen said that his experience in stenosis of the larynx had been limited. In one case, reported twenty years ago, he had removed a morbid growth by thyrotomy after it had been destroyed by the internal use of the galvano-cautery, which was probably the first use of the galvano-cautery for this purpose in the United States. The growth had been examined by several microscopists, who pronounced it epithelioma; but this was evidently an error, as the patient still lives. On this supposition I separated the thyroid cartilage and removed the tumor with one vocal cord. Preliminary tracheotomy had been performed ten days previously. The operation was followed by adhesion of the vocal cord to the tissues of the opposite side. He then had devised an instrument to cut this adhesion. He never had had the courage to attempt dilatation of the larynx without previous tracheotomy. It is better to perform tracheotomy so as to have nothing to interfere with the breathing, and then pursue the most active measures for the relief of the stenosis. When the operation is performed with antiseptic precautions the tracheotomy-wound heals up in a very short time. He had seen it close within four or five days of the operation. The danger from the operation is less than the risk of injury from the other methods of treatment.

Dr. E. C. Morgan recently had had under treatment a case of laryngeal stenosis. During a period of eight or ten months he was enabled to control this by the administration of iodide of potassium and by local applications of iodo-glycerin to the larynx. Finally, the disease advanced so far that on several occasions he advised tracheotomy, to be followed by dilatation. The patient postponed the operation, although warned of his danger. He had at times suffocative spells at night, and finally succumbed in one of these spasmodic attacks. If tracheotomy had been allowed and dilatation performed, that man would probably have been alive to-day.

Dr. Delavan: The various forms of dilators used in these cases are likely to be replaced by O'Dwyer's tubes. This method has a most promising future before it. The tube can be left in for a length of time and respiration go on uninterruptedly.

A paper was presented by D. Bryson Delavan on "The Etiology of Deflections of the Nasal Septum."

Dr. S. W. Langmaid read the next paper, on

FOREIGN BODY IN THE LARYNX.

The patient came under observation three months after swallowing a pin about two inches in length, which had lodged in the throat. Immediately after the accident an unsuccessful effort had been made to remove it with the bristle-probang. At the time that she came under the speaker's notice there were ulcerations of the larynx, which were relieved by treatment. Two years later the patient again presented herself, when an examination showed the pin, which had emerged from the ventricular band with the head down. It was with some difficulty removed.

A PECULIAR APPEARANCE IN THE PHARYNX.

Dr. J. Solis Cohen stated that in several instances he had seen, on examining the pharynx, what appeared to be the belly of a muscle above the Eustachian tube, and that from this there extended to the fornix of the pharynx what looked like a tendon. This he had seen on both sides. He asked whether or not any of the other members had observed the same appearance.

The report of a case of

RECURRENT NASO-PHARYNGEAL TUMOR; CURE BY ELECTROLYSIS,

was read by Dr. Rufus P. Lincoln, of New York.

The patient presented himself in April, 1886. A growth had been removed from the posterior nares by another physician one year previously. It returned, and the operation was repeated six months later. When the patient came under observation he was unable to breathe through the left nostril. On examination, a large growth was found occupying the left half of the posterior nares, and it was decided to treat this by electrolysis. On June 3, two needles connected with the negative pole of the battery were introduced through the anterior nares into the growth, while the positive pole terminated in two large sponge-electrodes which were applied to the front and back of the chest. In all sixteen applications were made, at intervals of three or four days. This caused an entire disappearance of the growth. The immediate effect of the electrolysis was to cause distention and a change in the color of the growth, but these passed off in the course of twenty-four hours. There is up to the present time no evidence of return of the growth.

DISCUSSION.

Dr. F. H. Hooper: In October, 1881, a youth presented himself with a tumor extending from the tip of the right nostril into the naso-pharyngeal cavity. There had been a great deal of hemorrhage, and the patient was in a bad condition. He was sent into the hospital and operated on by Dr. J. C. Warren with the galvano-cautery snare, and the whole

mass removed in one piece. From that time to this the patient has been constantly under treatment. The tumor has been growing, and from time to time has been snared off. The tumor has been pronounced to be a most malignant form of myxosarcoma, but the general health is excellent. He proposes to try the effect of electrolysis upon the growth.

Dr. D. Bryson Delavan said that during the past fifteen years he had seen a number of these patients operated upon, and recalled many cases in which the result was disastrous. Although there have been successful cases, none had come under his observation. The great point is in the early diagnosis. If taken in time, even if it cannot be cured, it can be kept in check as a rule. After the age of twenty-five years it has been stated that these tumors have a tendency to stop growing, so that if kept in check until this age they may entirely disappear. It seems to him that the galvano-cautery exercises a modifying influence on the tissues which remain which cannot be caused by the knife.

TWO UNIQUE CASES OF CONGENITAL OCCLUSION OF THE ANTERIOR NARES. BY W. C. JARVIS, M.D., OF NEW YORK.

Complete congenital occlusion of the anterior nares is rare, and the author has been unable to discover any cases in searching the literature of the subject. The first case was a young man 18 years of age, with complete closure of both nostrils. Inspection showed on each side within the anterior nares a cup-shaped depression of white, glistening membrane. On the left side a small hole was discovered. The operation was performed in April, 1886. The burrs devised by the speaker, connected with an engine, were used to cut through the cartilaginous occlusion. This was accomplished in a few minutes, and the air passed freely through the nostril. At a subsequent operation the right nostril was opened. In April, 1887, the opening in the right nostril had become contracted, and had to be reopened. In a second case, in which the anterior nostrils were occluded by an osseous growth, the operation was performed in the same manner as in the previous case, with success.

A COMPARATIVE STUDY OF SOME OF THE METHODS OF TREATMENT BEST ADAPTED TO THE RELIEF OF OCCLUSION OF THE POSTERIOR NARES. BY DR. ALEXANDER W. MACCOY, OF PHILADELPHIA.

The paper was restricted to the consideration of occlusion due to enlargement of the soft parts. He had never seen occlusion of the posterior nares due to osseous growth. He referred to the methods used in the treatment of occlusion of the posterior nares, and highly recommended the use of chromic acid fused on the end of a probe, the end of which is covered with a tube, which is withdrawn when the probe has reached the desired position. This is followed by the use of an antagonistic solution. He had found this better than the use of the galvano-cautery. After using cocaine he had not been able to use the cold-wire snare in these cases, on account of the contraction caused by the drug. He had also found difficulty in using the needles recommended by Dr. Jarvis. The chief object of the paper was to call attention to the superiority of chromic acid used in this way over the other methods of treatment which had been recommended. He did not recommend the use of the acid either in crystal or in solution, for then it was not easy to limit the application to the desired point.

DISCUSSION.

Dr. W. C. Jarvis never uses cocaine as a preliminary measure when he intends to remove posterior hypertrophies. He first includes the hypertrophies in the loop and tightens the wire before applying the cocaine spray. The tissue included in the loop cannot be affected by the contraction produced by the drug. We thus have the advantages of the anæsthetic without its disadvantages. It has been pretty generally recognized that chromic acid has many disadvantages. It may produce serious symptoms. The snare will accomplish in a few minutes what chromic acid requires considerable time to do.

Dr. C. C. Rice agreed in the main with the author of the paper. The turbinate bodies are difficult to penetrate with the needles, and there are many cases in which it is difficult to apply the loop posteriorly. He had not found any special disadvantages in the use of chromic acid.

Dr. D. Bryson Delavan formerly used chromic acid, but then gave it up. Lately he had again tested it, selecting for this purpose five patients, three of whom were physicians. He added enough water to the crystals to make them deliquesce, and then applied it with a cotton-wrapped probe, the excess of acid having been removed. He had also used it by fusing it on a probe. In all these cases there was more reaction than follows the use of the cautery or the snare, and all the patients preferred the cautery to the chromic acid.

A paper on "Plaster-of-Paris Dressing for Fracture of the Nose," by J. W. Robertson, M.D., of Detroit, was read by title.

Dr. De Blois, of Boston, exhibited a plaster splint which he had employed with advantage in a case of fracture of the nose. The splint consisted simply of a plaster cast into which a piece of roller bandage had been incorporated. This was applied over the nose and held in position by the strips of bandage.

Dr. J. O. Roe, of Rochester, exhibited a saw run by an electric motor.

The Association held an executive session,

during which the following business was transacted:

The report of the Committee on the Congress of American Physicians and Surgeons was presented and adopted.

The following officers were elected for the ensuing year:

President. — Dr. R. P. Lincoln, of New York.

Vice-Presidents.—Drs. J. N. Mackenzie, of Baltimore, and S. W. Langmaid, of Boston.

Secretary and Treasurer.—Dr. D. Bryson Delavan, of New York.

Librarian.—Dr. T. R. French, of Brooklyn.

Council.—Drs. Frank Donaldson, of Baltimore, J. Solis Cohen, of Philadelphia, F. H. Hooper, of Boston, and E. C. Morgan, of Washington.

The following were elected Corresponding Fellows: Dr. A. Gouguenheim, of Paris, and J. Moure, of Bordeaux.

Dr. A. Jacobi, of New York, was elected Honorary Fellow.

REVIEWS AND BOOK NOTICES.

A Text-Book of Pathological Anatomy and Pathogenesis. By Ernst Ziegler, Professor of Pathological Anatomy in the University of Tübingen. Translated and Edited for English Students by Donald MacAlister, M.A., M.D. Three parts complete in one volume. New York, William Wood & Co., 1887. 8vo, cloth, pp. 1091.

The translation of the second German edition of Ziegler's text-book of pathological anatomy by Dr. Donald MacAlister has placed a valuable work of reference in the hands of English-speaking students. Of the twelve parts into which the book is divided, seven are devoted to general, and five to special, pathological anatomy. The annotations made by the editor give additional value to a work which is encyclopædic in its completeness. The pages are illustrated by numerous cuts, and the type is clear and readable. Altogether, it is a most satisfactory book for students.

Transactions of the New York State Medical Association for the Year 1886. Volume III. Edited for the Association by Alfred Ludlow Carroll, M.D.

This handsome volume of transactions is embellished with three portraits of distinguished deceased members: Austin Flint, M.D., Frank Hastings Hamilton, M.D., and John P. Gray, M.D. Among the important papers are the President's Annual Address, by E. M. Moore, M.D., of Rochester, on "Subluxation of the Radius from Extension in Young Children;" "The Discussion on Shot Wounds of the Intestines," introduced by E. S. Tremaine, M.D.; "On Pulmonary Tuberculosis," introduced by H. D. Didama, M.D.; and "On Eclampsia," introduced by W. T. Lusk, M.D. A number of communications upon other subjects also appear, but the chief interest of the meeting was given to the consideration of the important questions just named.

NEW REMEDIES AND CLINICAL NOTES.

A New Form of Inflammation of the Lips and Mouth.—In a paper read by Jonathan Hutchinson, F.R.S, LL.D., before the Royal Medical and Chirurgical Society of London, on a form of inflammation of the lips and mouth which sometimes ends fatally, and is usually attended by some disease of the skin, the distinguished author discussed his subject most thoroughly. The disease is one which it is believed has not been previously recognized, in which the superficial ulcerations occur in the lips and in various parts of the mouth, followed sooner or later by some form of skin-disease and tending to end fatally. The form of skin-disease may vary, but the hands and feet are the parts usually affected, and the nails are especially prone to suffer. In some instances the eruption may consist of bullæ which are followed by free papillary outgrowths. The patients attacked are usually in middle life or in early senile periods. No special antecedents can be alleged as the probable cause of the malady. Unless checked by treatment, the disease appears to run its course in about six months, producing death by exhaustion. There seems reason to believe that opium given in repeated doses will cure it. All the best-marked cases as yet observed have occurred in males, but in several milder ones the patients were women. Of the most characteristic, two were master-tanners, one a farmer, one a clergyman, and one a gentleman of no occupation; all these resided in the country. Careful inquiry has failed to support the suspicion that the disease might perhaps be due to contagion from animals. Of these five cases, two ended fatally. The patients who died were those first observed, and since the discovery of the efficacy of opium no case has ended in death. The observation of the value of opium was simultaneously made by the President of the Society, Mr. Pollock, and by the author, two different patients being at the same time under their separate treatment and recovering under this drug. Since then every case has yielded if the opium were sufficiently pushed. In one, however, the disease did not yield quickly, and for more than a month seemed likely to terminate fatally.

As regards permanency of cure, in one case the patient is known to have been quite

well four years after his recovery, in another there is reason to believe that such is the fact, and in the third a period of two years has elapsed. In two of the milder cases occurring in younger patients, the disease has repeatedly relapsed.

A great variety of remedies had been tried without benefit before opium was used. In no single instance has there appeared to be any tendency to spontaneous improvement.

In all the cases the inflammation of the lips and mouth took definite precedence of the skin-symptoms, and in some the latter were very slight. It is not known that any case has as yet been obtained among the poorer classes of society.

The author desires to abstain for the present from expressing any definite opinion as to the causes or nature of the malady. He would, however, venture to suggest that it is allied to other forms of skin-disease in disturbed health and occurring in early senile periods, such as certain peculiar varieties of psoriasis, pemphigus, lichen planus, and pityriasis rubra. In confirmation of this suggestion, and as an appendix to this paper, a case is narrated (with a portrait in illustration) in which an elderly lady had a kind of spreading eczema-psoriasis of the hands and scalp. She lost all her nails and hair, and was rapidly failing in health despite various methods of treatment, but finally recovered quickly and completely under opium. Her case does not belong to the group described in the paper, because she never at any time had buccal disease.

Dermatitis Gangrænosa Infantum.—H. Radcliffe Crocker, M.D., read a paper before the Royal Medical and Chirurgical Society, June 14, 1887, on this subject. Four groups of cases are described. In the first there was no evidence of varicella antecedent to the gangrenous or ulcerating eruptions, and in most it was distinctly negatived. In the second group are cases in which varicella preceded the sloughs or ulcers, which either developed immediately upon the varicella pustule or occurred as a sequela beginning in independent lesions. In the third group vaccination was the immediate antecedent. In the fourth group are placed certain cases of local gangrene resembling cancrum oris; but the individual lesions began in exactly the same way as the independent eruption which followed varicella, and there was a tendency to generalization, or at all events to extension beyond the region in which it started, in some of the cases. A general account of the disease is drawn up from an analysis of the preceding and other cases, and it is shown there is great difference in the severity of the eruption. In some the gangrenous patches were so numerous and extensive as to lead to the death of the patient in a few days, while on the other hand are cases of so mild a character that there were only superficially ulcerating pustules which came out in crops, thus protracting the disease as a whole for a considerable time, and usually accompanied by an intense pruritus. These milder cases appear to correspond with Mr. Hutchinson's varicella prurigo. Between the two extremes are cases of all grades of severity.

Comparison is made between the local and general gangrenous eruptions, and, among other things in common, it is shown that both attack girls more than boys, and occur about the same ages.

The conclusions arrived at are that the gangrenous eruptions are pathological accidents, so to speak, which in young children, especially when of tubercular constitution, might supervene upon any pustular eruption, although no doubt such a condition is much more common after varicella. Secondly, the determining factor is probably a micro-organism derived from without, though cultivation and inoculation experiments could alone prove the truth of this theory. Thirdly, the initial lesions, both of the local and general gangrenous eruptions, present the same characters.

Electricity for Arrested Lactation.—The patient was the mother of three children, all of whom had been brought up at the breast. The youngest had been fed in the same way for eleven months, when an attack of pneumonia interrupted this method of feeding. Two days later, when the infant was well enough to recommence, the secretion had completely ceased. This state of things persisted for a fortnight, during which the child, who refused other food, rapidly lost weight. It occurred to Dr. Aubert to try the effect of local faradization. The electrodes, well saturated with moisture, were placed right and left of each breast, and the current was graduated so as not to cause contraction of the pectoral muscles nor pain. After the first *séance*, which lasted twenty minutes, the right breast had evidently increased in size. The second day a few drops of milky fluid exuded, and on the third day a spontaneous flow took place in both breasts. On the fifth day the child was enabled to resume the breast-feeding, and further treatment had become unnecessary. A second observation is reported by Dr. Becquerel in a young woman of 20, in whom the lacteal secretion had been arrested in consequence of reiterated and intense mental emotion. After eight days' suppression, three *séances* of twenty minutes' duration sufficed to re-establish the secretion, which then continued in a normal way. The same result was obtained quite unexpectedly in a woman seven months after her confinement, where the arrest of the secretion had been immediate. Pierron, in a recent paper, stated his belief that by this means lactation could be caused in virgins.—*Lond. Med. Rec.*

MISCELLANY.

THE ENGLISH COMMISSION ON PASTEUR'S METHOD OF PREVENTING OR TREATING HYDROPHOBIA.—The British Parliamentary Commission, which has been engaged in the study of Pasteur's work for several years, has finally presented a report, which expresses confidence in the truth of Pasteur's claims with regard (1) to the presence of hydrophobia virus in the spinal cord of animals dying with the disease, (2) to its transmissibility to other animals by inoculation, (3) to the fact that animals can thus be rendered refractory to subsequent inoculations, or even the bites of rabid animals. Finally, it is highly probable, even after such bites have been inflicted upon unprotected subjects, that subsequent inoculation as practised by Pasteur is of service in preventing the development of the disease.

The committee observe, "Making a fair allowance for uncertainties and other questions which cannot now be settled, we believe it sure that, excluding deaths after bites by rabid wolves, the proportion of deaths in the two thousand six hundred and eighty-two persons bitten by other animals was between 1 and 1.2 per cent., a proportion far lower than the lowest ever estimated among those not submitted to M. Pasteur's treatment, showing, even at this lowest estimate, a saving of not less than one hundred lives."

The value of M. Pasteur's method is further confirmed by the results obtained in certain groups of his cases. Of two hundred and thirty-three persons bitten by animals in which rabies was proved, either by inoculation from their spinal cords or by the occurrence of rabies in other animals or persons bitten by them, only four died. Without inoculation it is more than probable that at least forty would have died. Further illustration of this successful result is shown among other additional groups of cases. Between the end of last December and the end of March, M. Pasteur inoculated five hundred and nine persons bitten by animals proved to be rabid, either by inoculation from their spinal cords or by the death of some of those bitten by them, or as reported on by veterinary surgeons. Of this number only two have died. One of these was bitten by a wolf a month before inoculation, and died after only three days' treatment. If we omit say one-half of these cases as being too recent, the other two hundred and fifty have had a mortality of less than one per cent., instead of twenty to thirty per cent.

"From the evidence of all these facts," the committee then say, "we think it certain that the inoculations practised by M. Pasteur on persons bitten by rabid animals have prevented the occurrence of hydrophobia in the large proportion of those who, if they had not been so inoculated, would have died of that disease; and we believe that the value of his discovery will be found much greater than can be estimated by its present utility, for it shows a method of inoculation by which it may be possible to avert after infection other diseases besides hydrophobia. His researches have also added very largely to the knowledge of this disease, and have supplied what is of the highest practical value,—namely, a sure means of determining whether an animal that has died under a suspicion of rabies was affected really with the disease or not."

MEDICAL BOOKS AND AUTHORITIES IN COURTS OF LAW.—The law in regard to medical books as evidence in courts of law is fairly and very intelligibly stated in a recent Kansas case, as follows. Dr. Campbell, a practising physician of more than twelve years' experience, testified as an expert, and, after showing some of the effects of chloroform upon the human system, was asked, "How is it regarded by medical authorities upon that subject, and by medical men who are authority upon that subject?" He answered, "It is regarded by writers on that subject, and by all men who have used it to any great extent, and by all universally, so far as I know, as a very dangerous agent, and an agent which, if pushed beyond a certain point, will produce death,—that is, is in danger always of producing death. To be sure, a great many men have used it a great deal, and have had no bad results from it." Although the courts are not uniform in their holdings upon the admissibility in evidence of medical and scientific books, the great weight of authority is that they cannot be admitted to prove the declarations of opinions which they contain. This is upon the theory that the authors did not write under oath, and that their grounds of belief and processes of reasoning cannot be tested by cross-examination.

THE WESTERN PENNSYLVANIA MEDICAL COLLEGE.—A graduating-class banquet, commemorative of the termination of the first year's lectures, was given by the Faculty on March 24, 1887. The number of graduates was twenty-two, the enrolment being sixty. The success of the first year of this school has been phenomenal. The trustees have erected a commodious college-building immediately adjoining the premises of the Western Pennsylvania Hospital. The corps of Professors in the Faculty numbers twenty-two, with an equal number of adjunct teachers and assistants. The next Fall course will begin September 27. A large proportion of the undergraduates have entered the Junior Class for the three years' graded course provided by the College. For Catalogue address Professor W. J. Asdale, Pittsburg.

A NEW MEDICINAL PLANT.—The leaves of the Gymnema Sylvestre of India, according to Professor Thistleton Dyer (in *Nature*), have the curious effect when chewed of abolishing temporarily the perception of sweet things by the tongue. Governor Elles, of Madras, is reported as having found that it "abolishes the power of enjoying a cigar." If it would abolish the taste for whiskey as well as tobacco it would be a valuable addition to our materia medica.

A BUREAU OF GENERAL INFORMATION.—Mr. Joseph B. Marvin, whose office is in the Corcoran Building, Washington, D.C., is the manager of "The Bureau of General Information" for research in the Library of the Surgeon-General's Office, which promises to be of considerable service to medical writers. The terms are one dollar per hour for research, ten cents a folio for type-writer transcripts, and thirty cents a folio for translations.

DR. PACKARD has removed to No. 1926 Spruce Street, Philadelphia.

OFFICIAL LIST

OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U.S. ARMY FROM JULY 3, 1887, TO JULY 16, 1887.

LIEUTENANT-COLONEL A. HEGER, SURGEON.—Ordered to Fort Columbus, New York Harbor.

MAJOR J. H. JANEWAY, SURGEON.—Ordered to Benicia Barracks as post-surgeon; also as attending surgeon at Benicia Arsenal, California.

CAPTAIN H. P. BIRMINGHAM, ASSISTANT-SURGEON.—Ordered to Fort Myer, Virginia.

FIRST-LIEUTENANT C. E. WOODRUFF, ASSISTANT-SURGEON.—Ordered to Fort Mackinac, Michigan.

CAPTAIN C. K. WINNE, ASSISTANT-SURGEON.—Ordered to Fort Wadsworth, New York Harbor.

CAPTAIN VALERY HAVARD, ASSISTANT-SURGEON.—Ordered to Fort A. Lincoln, Dakota Territory.

CAPTAIN L. M. MAUS, ASSISTANT-SURGEON.—Ordered to Fort Schuyler, New York Harbor.

CAPTAIN J. B. GIRARD, ASSISTANT-SURGEON.—Ordered to Fort Lowell, Arizona.

FIRST-LIEUTENANT J. D. POINDEXTER, ASSISTANT-SURGEON.—Ordered to Camp Poplar River, Montana Territory.

FIRST-LIEUTENANT C. N. B. MACAULEY, ASSISTANT-SURGEON.—Ordered to Fort Gibson, Indian Territory.

CAPTAIN C. B. BYRNE, ASSISTANT-SURGEON.—Ordered to Washington Barracks, District of Columbia.

CAPTAIN T. E. WILCOX, ASSISTANT-SURGEON.—Ordered to Fort Niobrara, Nebraska.

MAJOR H. LIPPINCOTT, SURGEON.—Ordered to Fort Union, New Mexico.

MAJOR P. J. A. CLEARY, SURGEON.—Ordered to Fort D. A. Russell, Wyoming.

MAJOR D. G. CALDWELL, SURGEON.—Ordered to Fort Assiniboine, Montana Territory.

CAPTAIN G. H. TORNEY, ASSISTANT-SURGEON.—Ordered to Fort Robinson, Nebraska.

CAPTAIN WALTER REED, ASSISTANT-SURGEON.—Ordered to Mount Vernon Barracks, Alabama.

CAPTAIN J. H. PATZKI, ASSISTANT-SURGEON.—Ordered to Fort Huachuca, Arizona Territory.

CAPTAIN R. G. EBERT, ASSISTANT-SURGEON.—Ordered to Fort Custer, Montana Territory.

FIRST-LIEUTENANT J. E. PILCHER, ASSISTANT-SURGEON.—Ordered to Fort Monroe, Virginia.

CAPTAIN J. DEB. W. GARDINER, ASSISTANT-SURGEON.—Ordered to Fort Washakie, Wyoming Territory.

FIRST-LIEUTENANT A. R. CHAPIN, ASSISTANT-SURGEON.—Ordered to Newport Barracks, Kentucky.

MAJOR W. H. FORWOOD, SURGEON.—Ordered to Fort Snelling, Minnesota.

CAPTAIN H. O. PERLEY, ASSISTANT-SURGEON.—Ordered to Fort Wayne, Michigan
S. O. 156, A. G. O., July 8, 1887.

MAJOR WILLIAM S. TREMAINE, SURGEON.—Ordered for examination by Army Retiring Board at Governor's Island, New York Harbor. S. O. 151, A. G. O., July 1, 1887.

S. O. 159, par. 2, A. G. O., July 12, 1887, assigns CAPTAIN W. MATTHEWS, ASSISTANT-SURGEON, as member of Army Retiring Board at Washington, D.C., and relieves CAPTAIN J. O. SKINNER, ASSISTANT-SURGEON.

CAPTAIN J. O. SKINNER, ASSISTANT-SURGEON.—Granted leave of absence for four months, on surgeon's certificate of disability. S. O. 151, A. G. O., July 1, 1887.

CAPTAINS L. M. MAUS AND H. O. PERLEY, ASSISTANT-SURGEONS.—Ordered to accompany the Eleventh Infantry in changing station from Department of Dakota to Department of the East. S. O. 158, A. G. O., July 11, 1887,

CAPTAIN E. F. GARDNER, ASSISTANT-SURGEON.—Ordered to accompany the Twelfth Infantry from Madison Barracks to Duluth, and to return with Eleventh Infantry. S. O. 143, Division of the Atlantic, July 13, 1887.

CAPTAIN R. G. EBERT, ASSISTANT-SURGEON.—Will, in changing station from Fort Hamilton, New York Harbor, to Fort Custer, Montana, accompany the Twelfth Infantry from Department of the East to Department of Dakota. S. O. 159, A. G. O., July 12, 1887.

A Board of Medical Officers, to consist of MAJOR J. S. BILLINGS, SURGEON, CAPTAIN W. MATTHEWS, ASSISTANT-SURGEON, CAPTAIN F. C. AINSWORTH, ASSISTANT-SURGEON, is constituted to meet in this city for the examination of a candidate for admission to the Medical Corps of the Army. S. O. 157, A. G. O., July 9, 1887.

FIRST-LIEUTENANT H. S. T. HARRIS, ASSISTANT-SURGEON.—Will be relieved from duty at Fort Ringgold, Texas, upon the return of Assistant-Surgeon W. F. Carter, and will then report to commanding officer at Fort McIntosh, Texas, for duty. S. O. 73, Department of Texas, June 27, 1887.

FIRST-LIEUTENANT F. V. WALKER, ASSISTANT-SURGEON.—Granted leave of absence for four months. S. O. 160, A. G. O., July 13, 1887.

FIRST-LIEUTENANT JULIAN M. CABELL, ASSISTANT-SURGEON.—Ordered for duty as medical officer at Department Rifle-Camp, near Bellevue, Nebraska, August 1 next. S. O. 66, Department of the Platte, July 8, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U.S. NAVY FOR THE WEEK ENDING JULY 9, 1887.

MEDICAL-INSPECTOR A. HUDSON.—Detached from the "Trenton," and wait orders.

MEDICAL-INSPECTOR W. K. SCOFIELD.—Ordered to relieve Medical-Inspector Hudson on the "Trenton."

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U.S. MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDING JULY 16, 1887.

LONG, W. H., SURGEON.—Granted leave of absence for thirty days, on account of sickness, July 12, 1887.

AUSTIN, H. W., SURGEON.—Granted leave of absence for thirty days, July 16, 1887.

WATKINS, R. B., ASSISTANT-SURGEON.—Relieved from duty at Marine Hospital, Detroit, Michigan; ordered to assume charge of service at Evansville, Indiana, July 9, 1887.

PHILADELPHIA MEDICAL TIMES.

PHILADELPHIA, AUGUST 6, 1887.

ORIGINAL ADDRESS.

ADDRESS IN MEDICINE.

Delivered at the Thirty-Eighth Annual Meeting of the Medical Society of the State of Pennsylvania, held at Bedford Springs, Pa., June 30, 1887.

BY FRANK WOODBURY, M.D.,

Professor of Therapeutics, Materia Medica, and Clinical Medicine in the Medico-Chirurgical College of Philadelphia, etc.

VIRCHOW, in a public address, recently declared that "disease has a material *ens:* its physical basis is the altered cell." This is the epitome of modern pathology and the problem of therapeutics. The possession of definite conceptions of the nature of disease based upon exact observation, both *intra vitam* and *post mortem,* distinguishes the medical science of to-day, and places it strongly in contrast with that of any preceding age. The employment of instruments of precision and the utilization of the results of the marvellous development of the other departments of science have enabled medicine to advance with such strides that to many its present condition appears a revelation, if not a revolution.

Increase of knowledge brings increased responsibility, and more accurate information concerning the nature of disease necessarily leads to improved therapeutics. The influence of recent advances in pathology upon our methods of treating disease, therefore, is the special topic which I wish to present for consideration in this address.

It was observed by the late Professor Flint that in many directions imperfect physiological knowledge had retarded the progress of pathology and of therapeutics. Is it not the case, at the present moment, that our knowledge of both physiology and pathology has apparently far outstripped that of the power of healing? Recent applications of such knowledge in sanitary science, by controlling epidemic outbreaks of yellow fever, smallpox, and cholera, and by successful disinfection, encourage the hope that equally great if not greater advances in sanatory medicine are just before us, if not actually within our grasp.

I would err if I failed to give a prominent place to the advances in medicine due to bacteriological studies, and to the discovery that most of the zymotic diseases are accompanied by the parasitic development and growth of living micro-organisms upon which the symptoms apparently depend. Moreover, similar organisms have also been found to be present in diseases which had not been previously considered infectious, such as pneumonia and meningitis. But before we hastily adopt bactericidal methods of therapeutics, we should be quite certain that they are the active agents in producing the symptoms, and that the welfare of the patient will not be imperilled. "Take care," says M. Peter, to the Paris Academy of Medicine, "take care lest in raising a club to strike the bacillus you do not at the same blow kill your patient."

The distinction is not made as often as it should be between bacterial infection and bacterial poisoning. Living bacteria must feed, and consequently must excrete. In some varieties of them the excretions are poisonous, and in others the excretions appear to be harmless to the human organism. The poisonous excreta are often of the nature of ptomaines. Pasteur has demonstrated that the virulent power of the bacteria of splenic fever is not a constant quantity: it can be intensified by propagation or rendered progressively weaker by cultivation, the organisms retaining their specific identity though losing their toxic powers. Wood and Formad have shown that diphtheria is probably caused by micrococci which are commonly found in the mouth, but which have acquired virulent properties in some unknown or accidental manner. Bacterial infection, therefore, does not always involve bacterial poisoning.

Since harmless micro-organisms may acquire toxic properties, some authorities believe that all toxic varieties were originally derived from innocent forms. A very interesting study of tuberculosis in birds* by J. Bland Sutton, F.R.C.S. (appearing in the *Journal of Comparative Medicine and Surgery* for October, 1886), led independently to the discovery of the identity of the disease in fowls and in man; and, secondly, to the inference that tuberculosis was originally communicated to man from the lower animals. A very suggestive and important hint is given as to the primary origin of the bacillus tuberculosis. It was ascertained that the disease prevailed to a great extent among grain-eating birds, that

* Ribbert, of Bonn, in 1883 had announced the fact that tuberculosis of fowls was identical with that of man.

the seat of local infection was the alimentary canal, and that the poisonous agent was tubercle-bacilli introduced with the food. It was found, moreover, that the excreta of the birds was a good breeding-place for bacteria, and that when grain was thrown upon the ground it became mixed with accumulated fæces, food-remains, moisture, feathers, etc., which thus were carried into the alimentary canal, together with numerous micro-organisms. "It is not improbable that the tubercle-bacillus may have its origin in this way," says Sutton, who further declares that "when microscopists shall have exhausted their endeavors in detecting specific differences among the infinite variety of micro-organisms, and then direct their endeavors towards the phylogeny of the various forms, they will possibly find that this remarkable bacillus, which be may fitly termed, with typhoid fever, a scourge and a bane of civilization, has been evolved from some harmless form, and that its peculiar character of thriving best at a temperature equal at least to that of the human body was first acquired by being transplanted into a medium, the chief constituents being *animal excreta*."

Nocard, who succeeded in inoculating tuberculosis from birds to mammals, thus proving the identity of the disease, believed that avian tuberculosis was acquired originally from human sputa or from the droppings of tuberculous cows; but Sutton considers this view as highly improbable. Furthermore, Sutton found that all that was necessary to check an epidemic of avian tuberculosis was to clean, whitewash, and ventilate the place where the fowls were kept.

This is in accordance with the clinical observation that external surroundings influence the development of pulmonary tuberculosis in the human subject. As directly bearing upon the question of the influence of the environment in causing the outbreak of phthisis, I may mention a valuable study of the distribution of this disease, entitled "Contribution to the Climatological Study of Phthisis in Pennsylvania," made by Dr. Wm. Pepper, published last year as the presidential address of the American Climatological Association.

The following are the points which are of special interest:

(1) Those portions of the State where phthisis is rarest are the most elevated, having a general altitude of fifteen hundred to two thousand, or, better still, of two thousand to three thousand feet, while in proportion as we enter districts of lower general altitude we find correspondingly increasing rates of mortality from consumption. (2) Some general correspondence is also observed between areas of greatest rainfall and the frequency of the disease. (3) In large cities the greater the crowding of population the greater the mortality from consumption. (4) Hereditary influence was frequently noted in replies to the circular sent out, and instances of supposed contagion were communicated by forty-five physicians.

It is quite evident that the tubercle-bacillus requires a peculiar condition of the tissues in order to develop, and that this condition of the tissues is likely to be encouraged or established by residence in a low, damp locality and by overcrowding. Culture-experiments have shown that this bacillus grows most rapidly at a temperature above that of the healthy human body,—a temperature, however, which is normal in birds, and among which the relative mortality is far greater than in man. An important point, therefore, in the therapeutics of pulmonary tuberculosis is to keep down the fever by the use of the antipyretics. As the treatment of phthisis will be discussed specifically by those who follow me, I do not consider it proper to speak of it further.

A great advance has been made of late years in the therapeutics of fever, as the result of a better understanding of normal thermogenesis and the pathology of pyrexia. The source of all the energies in the body is the food, which is largely consumed in maintaining the animal temperature. But, in addition to maintaining temperature, energy is required for building up the tissues and for supporting physiological functions, such as the circulation, respiration, secretion, and locomotion. In fever the regulating power is disturbed, and an excess of energy is manifested as heat, thus defrauding the tissues and weakening functional power, and causing wasting of tissues and bodily prostration, which are as characteristic of fever as is the elevated temperature.

In the discussion on Fever at the recent meeting of the American Association of Physicians, the belief appeared to be gen-

erally shared that too much attention had been given to the mere element of elevated temperature, and that it is not all of the fever process by any means. In the use of antipyretics we are to be guided by other features in the case, and while in some cases the temperature may be kept down by antipyrine it does not follow that the disease will be shortened by it or that relapses will be prevented. This does not deny usefulness to this method of treatment, but is a protest against routine practice. In typhoid fever, however, good results were reported from the early use of calomel followed by naphthalin in doses of sixty to eighty grains per diem, given during the first ten days. After this the treatment does not materially change the course of the disease, except that by preventing hyperpyrexia it makes the patient more comfortable. The fever process appears to be the result of lowering of function of certain nerve-centres by a poison circulating in the blood, the poison being in most instances connected with the growth of bacteria, but their presence is not necessary, since fever can be produced by the injection of peptones into the blood (as in Dr. Wood's experiments) or simply by fatigue.

If it be really the case that harmless bacteria may, under the peculiar circumstances mentioned by Sutton, become converted into the noxious or specific bacillus of tubercle, it certainly is not without analogy in other infectious diseases. The human alimentary canal contains many micro-organisms which especially develop during attacks of diarrhœa and dysentery. Under these conditions Lewis and Cunningham detected a comma bacillus resembling that described by Koch as peculiar to cholera Asiatica. A similar organism has been described in summer or sporadic cholera, differing in unimportant particulars from Koch's bacillus. If we would seek for the evolution of the true comma bacillus, let us go to the native home of the cholera in upper India. Here we find a native village among the hills, on the border of a lake, which supplies the inhabitants with drinking-water. During the rainy season the accumulated filth of the village is washed into the reservoir. In the dry and hot seasons the border of the lake is exposed to the sun and breeds micro-organisms, which are taken into the stomachs of the villagers over and over again until they acquire the necessary virulence to initiate an epidemic, which starts on its way around the world. The possibility of this conversion of the ordinary bacteria into septic forms is strongly advocated by Nägeli;* and Büchner, indeed, claims to have successfully evolved the bacillus of anthrax from the ordinary bacillus of hay-infusions (B. subtilis). Even though this claim should not be admitted, it must be acknowledged that there is a strong probability that infective bacteria have not always possessed their noxious qualities, but have acquired them somehow in the course of ages. It is quite evident, however, that the recognized varieties of pathogenous bacteria retain their properties with a certain tenacity, and this will explain why at the present time transformation of innocuous into noxious bacteria can occur but rarely and only under very exceptional and special conditions. P. Zweifel claims that the important condition is a deficient supply of oxygen.† In other words, even if the pathogenous bacteria do not represent biological species, they are apt to maintain the pathogenous forms for long periods of time.‡

The evolution of the specific element in yellow fever might be traced in a similar manner to that of the cholera bacillus.

The active agency in malarial intoxication is in all probability an instance of an ordinary microbic form becoming specialized under favorable conditions of temperature and soil, where animal and vegetable refuse is undergoing decay. The many attempts to isolate the bacillus malariæ, however, have failed to establish its specific identity. Comparatively recently Laveran has described a body existing in the blood of persons during the paroxysm of ague which is absent at other times. This has been confirmed by Councilman, of Baltimore, and Osler, of Philadelphia, who each affirm its great value in diagnosis. Since typhoid fever appears to succeed malaria in many communities, it is probable that the special bacillus of Eberth is likewise the result of the development of an ordinary zymogenic bacillus which has acquired specific properties from being kept for generations in contact with animal and vegetable refuse.

The investigation of the relationship of bacterial infection to disease brings us to the very important question of vital resistance. How can the human system be protected from being injured by the inroads of micro-organisms? Clinical experience has taught that by surviving one attack of most of the infectious diseases a change is wrought so that the system is proof against subsequent infection of the same malady. The disease may even be induced in a mild form, as by vaccination, or as in Pasteur's cultures of the micrococcus of splenic fever, and the vital resistance increased so as successfully to resist future attacks. It is believed that this is brought about by a process similar to acclimatization; the tissues becoming accustomed to the poisons generated by the bacteria, just as we see the organism becoming accustomed to the effects of other chemical poisons, such as nicotine, morphine, arsenic, or alcohol.* Some recent investigations seem to show that it is not necessary to introduce the poisonous bacteria themselves, but merely their chemical products, in order to obtain immunity from further infection. Chauveau claimed that vaccine lymph could be diluted one hundred and twenty times without losing its protective power; and it has been recently asserted that rabbits have been rendered proof against anthrax by injecting hypodermically a chemical solution, as predicted years ago by Toussaint and Paul Bert. It is a well-established fact that a course of quinine will enable a man to escape malaria, although exposed to the infection, and Tommasi-Crudeli, from experiments on workmen on the Roman Campagna, demonstrated conclusively the protective power of arsenic in the same manner. The therapeutic use is closely related to prophylaxis. If the experiments of Pasteur in hydrophobia may be accepted as establishing anything conclusively, it is that hydrophobia is curable by a chemical agent of the nature of a ptomaine derived from the spinal marrow of infected animals.

It is a fact believed to be established by experience that the daily use of sulphuric acid or alcohol during a cholera epidemic will prevent infection. This is not without consolation for those who fear infection from the ubiquitous tubercle-bacillus. Possibly the use of alcohol, so strongly advocated by Flint in incipient phthisis, may be a highly rational treatment, after all, for the prevention of tuberculosis.

Freire is conducting on a large scale an experiment by inoculating thousands of laborers with cultures of the micrococcus xanthogenicus; but if the same result can be achieved by some chemical agent, it would be a decided step in advance.

As a further result of these studies, it is very evident that the human body is prepared for all kinds of disease by unwholesome surroundings and bad hygiene. Parents living under such conditions have offspring that are ready to succumb to any disease on account of defective vitality.

Many children come into the world with the verdict "unfit to survive" stamped upon them. They furnish the great number of deaths from so-called cholera infantum during the first two years of life. Much of this, according to my view, is a necessary mortality on account of defective vitality. If they grow up, some organ which is especially vulnerable is constantly giving trouble by breaking down.

Dr. Budd called attention to the congenitally insufficient liver as a prolific source of bilious attacks and gout. Relative smallness of the heart and pulmonary artery, also congenital, is one of the recognized predisposing causes of pulmonary disease in later life. Weak digestive powers have great capacity for producing migraine, melancholia, and manifold miseries. Renal inadequacy, inherited or acquired, is the cause of lithæmia, headache, and nervous symptoms, as well as other physical disorders, such as eruptions on the skin.

The field of future medicine is therefore limited by the perfectibility of the human race. Disease exists because some families around us are in process of extinction and are more or less defective, while others, by reason of superior vitality, are building up types that are destined to survive in the struggle for existence. Statistics might be given to show what service has already been rendered by medicine in ameliorating the conditions of existence, lengthening average human life, and reducing the inroads of disease. The single operation of ovariotomy, it has been computed, has added thousands of years to woman's life; but who could compute the number of

* Prof. James Law, F R.C.V.S., ably defends this view in a paper on "The Rôle of Microbes and their Chemical Products in the Causation of Disease," *Journal of Comparative Medicine and Surgery*, August, 1886.

years given to humanity by the practice of vaccination or by the introduction of antiseptic methods into surgery?

In illustration of the benefits of the recent improvements in surgery in what is usually considered the field of medicine proper, I may cite the diagnosis and removal of intracranial growths, ten cases of which, with only two deaths, were reported by Mr. Victor Horsley during the past year, the removal of hydatid cysts from the lungs, as reported by Dr. Fenger, of Chicago, the resection of the ribs for chronic empyema, aspiration of the chambers of the heart for acute over-distention, the pyloric resections in cases of cancer of the stomach, and various operations upon the other viscera, which until recently were considered beyond the aid of art. Recently I had the honor of reporting a case of perityphlitic abscess to the College of Physicians of Philadelphia, in a man of twenty-six years of age, who had the operation of laparotomy performed, the abscess freely opened, and the diseased vermiform appendix amputated, followed by complete recovery in less than a month after the operation. In cases of acute perforation of the bowel in typhoid fever, Dr. J. C. Wilson, of Philadelphia, recommends opening the abdomen and treating the case as a perforating wound or acute obstruction of the bowels. If modern surgery has enlarged our therapeutic resources, it has also increased our ability to interpret symptoms, for which we are largely indebted to the labors of the skilful specialist. Hay fever is now understood to be a neurosis associated with nasal hyperæsthesia. Headaches are frequently caused by eye-strain. Some cases of bronchial asthma are demonstrably dependent upon nasal hypertrophies. Pelvic disorders in women are seen to be the true cause of much general ill health. Dr. S. W. Gross claims that similarly a pain in the back in the male may be caused by an over-sensitive urethra, and I have even noticed lately that Dr. Orendorff, of Louisville, goes so far as to declare that locomotor ataxia may be caused by urethral disease, and that the majorities of ataxics have stricture of the urethra.*

Dr. T. G. Morton, in a paper published in the *Philadelphia Medical Times* for July 10, 1886, has shown the true explanation of some cases of supposed lateral curvature of the spine, in the want of symmetry of the length of the lower extremities. Many cases of persistent pain in the back may be cured by simply elevating the heel of one shoe so as to make both legs of equal length.

Very much of the defective development of adults, I fear, is traceable to an undue amount of application required of children in school life. The ill effect of excessive brain-work upon the development of the teeth has been noted, but we are not in a position to estimate the impairment of other digestive organs, except by the frequency of indigestion among young adults. The book of nature is much more attractive to children than dead languages and doubly dead authors. Our children do not compare in their physical development with young savages. We are almost tempted to echo the wish of the laureate, to return once more to a state of nature, and rear a

"dusky race.
Iron-jointed, supple-sinewed, they shall dive, they shall run,
Catch the wild goat by the hair, and hurl their lances in the sun;
Whistle back the parrot's call, and leap the rainbow of the brooks,
Not with blinded eyesight poring over miserable books."

The introduction of physical exercises in higher colleges is well; but are they not more needed in the preparatory schools? It is an encouraging sign that the attention of the profession is turning again to gymnastics as a therapeutic measure. Dujardin-Beaumetz has recently delivered a lecture highly extolling the effects of kinesitherapy, as he styles it, in the treatment of many diseases, notably diabetes and gout. The Swedish movement cure is becoming better appreciated as it is better known by the profession. In many disorders well-regulated exercise is a necessity. Bouchardat used to insist upon his diabetic patients cutting their own wood, practising fencing, and other gymnastic exercises. Chomel said that they should digest with their legs. An important part of the celebrated Clemens treatment of diabetes was open-air exercise.

"Leb' mit dem Vieh als Vieh
Und acht es nicht fur Raub
Den Acker den du pflügest, selbst zu düngen,
Das ist das beste Mittel, glaub',
Auf hundert Jahr' dich zu verjüngen."

Mental strain is now recognized as a prolific cause of diabetes. In the treatment of such cases, the question of diet becomes less important than the adoption of a more

* Progress, 1886, p. 162.

natural course of life. It is also significant that the late Willard Parker, from his very great experience, gave it as his deliberate conviction that mental anxiety is one of the chief causes of cancer of the breast. Those twin jailers, iron fortune and lowly birth, with the ambition to get on in the world, are responsible for a large amount of sickness in the community. Many have no time to consider the question, "How shall I keep well?" since their whole mind is occupied with the problem, "How shall I get a living?"

We are forcibly reminded of the old physician in one of Balzac's novels ("*Cousin Pons*"), who declares, "I have spent my life in seeing people die, not of their diseases, but of that great and incurable malady, the want of money."

In this direction the community is in need of good advice. It should pay more attention to maintaining physical health by physical exercise. I have been struck by the fact that the large hospitals, as a rule, have no means for systematic exercise as part of the treatment; the patients spend their time in absolute idleness. Every hospital should have its gymnasium. Massage is becoming more used in this country with decided advantage to patients. It is not in America, as yet, used regularly to any extent in health, as it is in Japan, where it is very popular under the name of the "body-regulating art." Dr. Norton Whitney, of Tokio, wrote a letter to the *Philadelphia Medical Times* some years ago, on the "Employment of the Blind in Japan," in which he recommended teaching massage to the blind in this country as a means of earning a livelihood. We hope to see this adopted; the demand will increase with the supply. One or more practitioners of massage should be attached to each hospital in the land.

While on the subject of constitutional weakness, let me say that a prolific source is the inability of mothers to nurse their infants, and the inevitable resort to the various forms of infants' food. I have lately noticed that by the application of faradism to the mammary glands after confinement, the flow of milk can be induced. Not only this, but the novel statement is made that a flow of milk may be induced in the breasts of virgins by the same means. This affords a source for an unlimited supply of wet-nurses, with a corresponding reduction in the consumption of various baby-foods, and possibly also a marked decrease in the mortality from "teething" and "summer complaint."

One of the most hopeful evidences of advance in medicine is the growing appreciation of the work of the general practitioner. There are signs of a healthy reaction against the dogmatism of the laboratory and the arrogance of a narrow specialism. Professor Leyden, as president of the recent German Congress of Internal Medicine at Wiesbaden, has well defended this view. He says, "The present age is scientific and experimental, and medicine has partaken of the general tendency, and has become an experimental science. But the scientific and experimental work in the laboratory, upon which so much weight is placed, and which has unquestionably contributed to exactness in our knowledge, fails to answer the demands of the present, however much it may promise for the future. The living present has claims which the physician must not overlook in his zeal for mathematical exactness in diagnosis and mechanical treatment. It is time to remind the practitioners of our day that the inexhaustible source of all knowledge and progress in medical art is observation at the bedside of the patient. Experiment is one-sided, complete knowledge of disease can be gained only by studying cases." "The true function of medical art is not to treat diseases, but to treat persons who are sick." The study of the individual needs of the patients under our care, in order to adapt our remedies to their requirements, is the path by which Hippocratic medicine has advanced and must continue to advance. It was this that led Paré to substitute the ligature for the cautery for the relief of hemorrhage on the field of battle, which led Hunter to tie the artery in its continuity for the treating of the case of the coachman with popliteal aneurism, that led McDowell to perform ovariotomy, or Sims to his operations upon conditions which hitherto were beyond the reach of medical art. Thus it is that the general practitioner fulfils the dictum of Hippocrates: "Medicine consists of addition and subtraction—the subtraction of that which is redundant and the addition of what is deficient, and he that does these things best is the best physician, and he that is most removed from this system is the most removed from a knowledge of the art."

ORIGINAL COMMUNICATIONS.

REPORT ON THE PROGRESS OF OTOLOGY.

BY CHARLES H. BURNETT, M.D.,
Professor of Otology, Philadelphia Polyclinic.

CYSTS OF THE AURICLE.

DR. H. SELIGMAN, of Frankfort-on-the-Main, publishes a short account of the occurrence of a cyst in the auricle, which he considers corroborative of the views advanced by Hartmann, some time previous, in the *Archives of Otology* (*Archives of Otology*, vol. xvi. p. 41, 1887).

Mr. W., 35 years old, with sound intellect, applied to Dr. Seligman in May, 1885, for relief from a swelling of two months' duration, in the usual situation of an othæmatoma, between the upper portions of the helix and the anthelix of the right auricle. The skin was very tense and somewhat hot. The swelling was the size of a walnut, round, tense, smooth, and not tender to the touch. The rest of the cartilage was normal, and traumatic influences could be positively excluded. The patient would not consent to an incision. The tumor was therefore tapped by means of a Pravaz syringe, and about three cubic centimetres of a thick, transparent fluid, of a light yellow color, was drawn off.

The point of puncture was then covered with a piece of adhesive plaster, and the pinna being padded with cotton, a bandage was applied. There was a slight reaccumulation of the fluid, but subsequently the ear assumed a normal appearance without further treatment.

The morphological elements contained in the fluid were mucous filaments, some white and a few red blood-corpuscles. This circumstance, in connection with the absence of pain and traumatism, and the good general health of the patient, renders it likely that this was a cyst and not an othæmatoma. In regard to treatment it is suggested that multiple punctures be tried in preference to incision, the latter being resorted to if the former fail.

THE CAPACITY OF THE AUDITORY CANAL.

Both Von Troeltsch and Kirchner have placed the average length of the auditory canal at twenty-four millimetres. The latter dimension has been placed at twenty-four and four-tenths millimetres by Bezold, the minimum being twenty-one millimetres, and the maximum twenty-six millimetres. But no one has, so far, endeavored to determine the capacity of the auditory canal. Dr. Hummel, of Munich, has, however, made a long series of examinations, two hundred in all, upon soldiers between the ages of twenty-two and twenty-four, in order to determine the capacity of this important canal, both in health and in disease. (*Archiv für Ohrenheilkunde*, Bd. xx. pp. 263–299, May, 1887.) The average capacity of the normal right auditory canal is one and seven-hundredths cubic centimetres; of the left, one and five-hundredths cubic centimetres.

Pathological cases—viz., otorrhœa with perforation of the membrana tympani, upon one side, with intact normal ear upon the other—furnish marked differences in cubic capacity. Thus, the healthy side may have a capacity of one and six-tenths cubic centimetres, while the diseased side may have a capacity as high as four and two-tenths cubic centimetres.

By a comparison of such differences in a given case, some idea can be formed of the extent of the destructive process, and the author claims to have pointed out a new diagnostic means.

CHRONIC PURULENT INFLAMMATION OF THE TYMPANIC ATTIC.

Dr. H. N. Spencer, of St. Louis, Missouri, having several cases of attic disease under treatment, has contributed a short paper on their nature and treatment. (St. Louis *Courier of Medicine*, May, 1887.) Chronic purulent inflammation of the attic may be limited to this cavity or be associated with a similar process in the atrium. It may have had its origin in the attic or have resulted from extension of inflammation. Dr. Spencer has not observed any special tendency on the part of attic disease to pass into mastoid disease. This conclusion is based on eighteen years of experience with aural remedies. "We have not infrequently, in the course of a purulent inflammation of the middle ear, especially in its exacerbations, indications of mastoid cell disturbance. Sometimes there is considerable pain, with tenderness upon pressure behind the ear, and external redness and swelling. These symptoms may be present to an alarming extent, and will disappear with no special attention being directed to them beyond a continuance of care for the middle-ear trouble,

except that I am in the habit of prescribing a few grains of calomel under these circumstances in combination with quinine. I have known repeated recurrences, all finally yielding to improvement in the general health and the bettered condition of the tympanum." Subsequently a further very pertinent allusion is made to mastoid disease in general: "Either diseases of the mastoid are of less frequent occurrence in the West than in the East, and less in this country than abroad, or perforation of the mastoid process is often unnecessarily performed, and an overweening desire to add to a number of operations magnifies the subjective and objective indications for surgical interference, and prejudices the otherwise good judgment of the operator. I make this statement with some hesitation, but from a conviction of the truthfulness of it so far as *my experience* has gone, founded upon upwards of twenty-five thousand cases of ear-disease seen in private and hospital practice."

Pathology.—There are said to be two forms of purulent inflammation of the attic, one characterized by swelling and a tendency to proliferation and organization of tissue, and the other by a thinning of tissue, or tissue-waste. The opening through which drainage takes place is in Shrapnell's membrane, or the flaccid membrane of the tympanum, that portion above the folds of the membrana tympani. In the first-named form, the hyperplastic, the edges of the perforation and the surface of the cavity beyond are red and swollen. Sometimes there are found villous projections, papillary growths, and even large polypi. In the second form, that of tissue-waste, the edges of the opening in the membrane are thin and white, and the tissues in the attic beyond have the same appearance. The discharge is often scanty, and dark brown in color. It may even harden into a black mass, assuming the shape and mould of the cavity, a slow process of waste going on beneath. This second form is considered by Dr. Spencer to be the more intractable of the two, and more likely to result in caries of the bone. The head of the hammer first, and next in point of frequency the head of the incus, are liable to become affected by carious action.

Treatment.—It is recommended in those cases of suppuration of the attic that present polypi or polypoid masses to operate for their removal at once, and to curette the mass or masses as high up as it is possible to do so. An anæsthetic may be employed or not, as seems necessary. Immediately after the operation Dr. Spencer employs a saturated solution of nitrate of silver, "which, being taken up on a tightly-twisted bit of cotton, projects one-sixteenth of an inch beyond the point of the holder, and, bent at a right angle with the shank, is passed over the margin of the plate and carried well up into the cavity." It does not seem necessary to neutralize this, but to dry the parts well with absorbent cotton to prevent excess of the fluid. The operation and the caustic are to be followed by the application of absolute alcohol or a saturated solution of boric acid in absolute alcohol, by instillation. It is to be understood that during this course of treatment the ear is to be kept very clean. The discharge is usually quite abundant.

In the second class of cases the treatment is different. In this form of disease atrophic processes are to be combated by a stimulating method. Here peroxide of hydrogen is employed, being slightly stimulating and somewhat disinfecting. Nitrate of silver is also advised, but all stimulation must be mild. The pus-cavity can be cleansed with the tympanic syringe, but not too frequently, as the repetition of this method at short intervals is prejudicial to speedy healing. The form of cotton-holder is of importance, steel being the only efficient kind. The shank must be slender, and the point unnotched. The point can be improved by subjecting it to acid.

CHRONIC CATARRHAL INFLAMMATION OF THE MIDDLE EAR.

Dr. Albert H. Buck, of New York (*Medical Record*, January 1, 1887), has contributed a paper on this subject, representing his conclusions as to the seat, the cause of this disease, and also its treatment, based on personal observations of cases during the past fifteen years. Formerly attention was directed chiefly to the Eustachian tube and middle ear, while the pharyngeal vault was overlooked, and he might have added the nares too. Now the pharyngeal centre is considered more important, and to it treatment is directed. The causes are manifold and complex. Cold in the head, the metabolic processes of assimilation

and metamorphosis, tobacco-smoking, climate, clothing, hygienic mistakes in either too much or too little ventilation of apartments, by day and by night, and finally the retention and inspissation of secretion in the crypts of the tonsils. It is recommended to explore these half-dozen crypts wherever the tonsils are found enlarged and show a tendency to congestion. For this purpose a slender ring-shaped curette of steel, with nicely-rounded edges, may be used both to explore and cleanse the crypts of foul-smelling, cheesy matter. After that the cavities should be syringed with listerine and water, one part to two or three of water.

If sclerosis of the mucous membrane in the drum-cavity and stiffening of the bones have not occurred, but if the disease is still in the hypertrophic and hyper-secretory state, it is reasonable to hope for benefit from treatment. Pains must be taken to find out whether the case is made worse by tobacco-smoking or undue exposure to draughts of cold air during sleep, or whether the disease "owes its chief activity to a lithæmic diathesis." One or two cigars a day may be allowed. No cold draught should be allowed to fall on the head while sleeping; but opening of all the windows of the sleeping-rooms in cold weather seems too rigid a course of management of chronic aural catarrh. The lithæmic taint must be overcome if the local treatment is to have a good effect. The amount of food must be carefully inquired into, and also the daily exercise. A full-grown man should get at least four miles of walking in the open air daily. Coffee, pastry, and all alcoholic drinks must be abandoned. "A warm bath every night, followed by brisk rubbing with a coarse towel, will stimulate the skin to perform its emunctory functions with increased vigor."

In the local treatment chief reliance is placed upon nitrate of silver and tincture of iodine applied to the naso-pharynx, because they are "the most efficient remedies known, in respect to their power to diminish undue vascularity, infiltration, and hyper-secretion of a highly glandular mucous membrane." Nasal sprays do not seem to enter largely into the methods employed by Dr. Buck, although he has succeeded in relieving tinnitus aurium by a spray of listerine and water, one part to three.

AURAL DISEASES FROM MALARIA, AND AUDITORY DISTURBANCE FOLLOWING THE USE OF SULPHATE OF QUININE.

There are few subjects more difficult to study than auditory diseases caused by malaria, and there is constant confusion between the phenomena due to malaria and those due to the administration of the sulphate of quinine. Weber-Liel's work on this subject is both the oldest and the best. He holds that the paludal poison may affect the ear in two ways,—viz., by an inflammatory process, and by a non-inflammatory process (otalgia intermittenta). In both cases it is the third branch of the trigeminus in the tract in which occurs either a paludal neuralgia or vaso-motor disturbances leading to inflammation.

Ferreri (*Annales des Maladies de l'Oreille, etc.*, May, 1887) has made a recent study as to what part in the production of aural diseases may be ascribable to malaria, and what to quinine. He therefore gave large doses of quinine to thirty patients suffering with malaria, but unaffected in their ears. The subjective symptoms following the drug manifested themselves four hours after its administration, but in no case was there pain in the ear, and in twenty-four hours all subjective symptoms had disappeared. Again, in the Roman Campagna, where malarial diseases are so numerous, affections of the ear are rarely seen. In four thousand five hundred and seventy-four cases of ear-diseases observed in the otological clinic of Rome, between the years 1874 and 1886, only eight cases of malarial otitis were recorded. According to Ferreri, the acoustic nerve and the sensitive nervous branches of different parts of the ear are chiefly attacked, in chronic malarial cachexia, in the form of neuralgias more or less intermittent.

Quite an intense hyperæmia of the middle ear, with serous effusion into the membrana tympani, without ulceration of that membrane, is met in cases of acute malarial infection. The chief symptom thus induced is an intense boring pain, recurring at regular intervals. It is probable that in such instances the chief anatomico-physiological lesion is an irritation of the tympanic plexus. These lesions are characterized by (*a*) absence of suppuration, and (*b*) ready cure by means of quinine. Aural maladies from malarial poisoning are very rare in children.

A CASE OF NUTMEG-POISONING.

BY JOHN GILLESPIE, JR., M.D.

MRS. M., the mother of seven children, finding herself again pregnant, and acting under the advice of a friend, procured five nutmegs, grated them down, diffused them in warm water, and took the whole at one dose when just about to retire for the night.

Soon afterwards she fell asleep, and was awakened by one of her children crying, when she arose and walked steadily to the bureau to get a glass of water for the child, but on reaching the bureau found that she was unable to grasp the glass containing the water firmly enough to carry it.

On attempting to return to bed she staggered, and, on reaching the bed, fell on it rather than got into it. Until this time there had been no unusual sensations. In a few minutes her head began to ache and her face began to tingle and itch, and she "felt as if her head was turning around and around."

By this time the patient's husband had been aroused, and he noticed that his wife's face was very much flushed, and that she was bathed in perspiration.

Nausea now became very distressing, and the patient complained that her head and face "were swelling." For several hours these symptoms continued, with the addition of frequent and copious micturition.

When I reached the house, five hours after the symptoms first appeared, and about six hours after the nutmegs had been taken, I found the woman in the following condition: the face was very greatly flushed and swollen; the pupils were contracted but sensitive; the heart was pulsating at the rate of 130 a minute; the pulse was of fair strength and volume; nausea was very great, but there was no vomiting; there was no abdominal pain, nor did firm pressure over the abdomen cause any pain. The patient was perspiring very freely, and complained bitterly of frontal headache and of vertigo. There had been no purging.

I immediately administered an emetic of sulphate of zinc, gr. xxx, and awaited developments. In a few minutes the zinc produced emesis, and among the rejected matter were many particles of the grated nutmeg.

The emetic appeared to relieve the headache and vertigo, and the woman was much more comfortable for more than an hour, when, without any warning, there was sudden failure of the circulation, and all the signs of collapse came on. The face became pallid, the pulse very rapid and weak, the respiration hurried, and the patient's countenance betokened great anxiety.

Under the use of five-drop doses of spt. ammoniæ aromat., well diluted and frequently repeated, color returned to the face, the pulse became stronger, the respiration natural, and there were no further symptoms to cause alarm, and after a day in bed the patient was practically well, although the headache and the œdema of the face continued for several days, a small dose of castor oil completing the treatment.

By taking other nutmegs which were in the house and weighing them, I estimated that the weight of those taken by the woman was fully five drachms and a half.

The peculiar features of the case to me were the absence of abdominal pain and the fact that there did not appear to be any narcotic effect produced, as there was at no time any tendency to drowsiness.

The reason for using such a small dose of the aromatic spirit of ammonia was to guard against aggravating any tendency to abdominal or gastric irritation.

1434 South Broad Street, Philadelphia.

NOTES OF HOSPITAL PRACTICE.

PENNSYLVANIA HOSPITAL.

CLINICAL SERVICE OF JOHN H. PACKARD, M.D., ONE OF THE ATTENDING SURGEONS OF THE HOSPITAL.—RAILROAD CRUSH PRODUCING VENTRAL HERNIA—DISLOCATION OF RIGHT HIP JOINT—INCIPIENT ŒSOPHAGEAL STRICTURE, PROBABLY FROM EPITHELIOMA—CASES OF SUPRA-PUBIC CYSTOTOMY—OPERATION OF EXSECTION OR EXCAVATION OF ASTRAGALUS.

GENTLEMEN,—The man before you was caught last Monday between the bumpers of railway-cars. Fortunately, the effects of this crush were not very disastrous, and it was only on last evening that he presented himself at this hospital for treatment. You will notice quite extensive ecchymosis, widespread over the whole of the left lateral surface of the abdominal walls. Being now many hours old, this ecchymosis presents all the varied mixture of tint and shade and color of the "autumn leaf," and from the

same radical causes,—viz., it is due to the last pigmentary changes in the coloring matter of the blood before finally being partly absorbed.

On the man being directed to restrain his breathing, and again on being told to cough, you note first a large flattened swelling of the left groin, and then a decided impulse given to my hand and fingers, which are in close contact with the protruding surface.

Tracing this protrusion as to its boundaries, I find that its axial centre is above "Poupart's ligament," to the right of the anterior superior iliac spine, to the left of the outlined edge of the left rectus muscle. It is a true "ventral hernia." The crushing force of the injury lacerated the walls of the abdomen in their middle portions; the peritoneum remained intact, as well as the external covering of integument, but the muscular walls of the abdomen were thoroughly torn apart, thus permitting the contents of the cavity to push forward into this flattened but large ventral hernial sac. Here, by the way, let me say that umbilical hernia, which is frequently congenital, may exist at the umbilical ring or through the abdominal walls, and appear in the same locality, but there is a great difference in the two conditions.

As to treatment of the case before us, nothing more may be hoped for but that a properly shaped and sized pad with raised edges, held by a suitable truss and worn by the patient indefinitely, will result in the remote possibility of a reunion of the lacerated muscular and cellular tissue, and the formation of a hard cicatricial mass.

Case II.—This colored man, who is not only aged in appearance, but really older than he seems, was the sufferer on Tuesday last from a falling pier of masonry in a cellar-excavation, dislocating his right femur. On admission his aged look warranted the diagnosis of a fracture of the femoral neck, but on examination the case proved simply one of luxation of the head of the femur backward on the dorsum of the ilium. After etherization, I made use of manipulation, bending the knee, flexing the thigh upon the abdomen, and forcibly rotating the whole limb while abducting it. The head of the femur, however, while moving readily towards and around the acetabulum, refused to enter its old socket, and I was about having recourse to the pulleys as a means of extension, when in their stead I adopted the following means, which were successful. The patient lying on a folded blanket on the floor, and I sitting on a chair at his right side, I slung his knee of the injured side over my right knee, and had traction made on his foot, while his pelvis was firmly held down. Thus I got a very effective extension made, which in a few moments was successful, the head of the bone slipping into the socket with an audible snap. I think that some of the thickened ligamentous bands connecting the femoral head and neck with the spinous process of the ilium had acted as a bridle-like impediment to the entrance of the head into the socket, but when extension had been forcefully made in the above gradual manner there was a speedy restoration of the articulating surfaces.

Case III.—This colored patient complains of a slight dysphagia. I select a large, olivary, ivory-headed flexible probang, and will now pass it well upward and backward against the roof of the mouth, soft palate, rear of pharynx, and finally behind the epiglottis, and while he makes an effort at swallowing, I now pass it down the œsophagus into the stomach. On withdrawing it slowly, I find that just at the upper part near the pharynx there is a slight constriction, which in this case is probably epitheliomatous in character. It is best in these cases, as in those of stricture of the urethra, to use the largest available instrument, lest injury should be done to the mucous membrane; and all force should be carefully avoided, either in the introduction or in the withdrawal.

Case IV.—The next case, also a colored man, represents not only itself, but also another patient, a white man, older, and in a more serious plight, in both of which we have this week performed supra-pubic cystotomy.

These are cases of great interest to me, both by reason of my experience in at least twelve others of like character, and on account of the objections which have been urged against the operation. These objections, as I shall demonstrate to you, are of no weight provided the procedure is made with proper precautions and in the light of nineteenth century surgery. In both cases, which entered the hospital within a period of thirty-two hours, there was inordinate distention of the bladder.

There had been the usual futile attempts made at catheterization, there had been a forceful pushing at and "ploughing up" of the enlarged prostate gland in both, followed by the usual hemorrhage, pain, anxiety, and shock. One case also was suffering with double inguinal hernia and double hydrocele.

In both cases we made the usual incision through the integument an inch and a half in length above the pubes. If the incision be made low and near the pubes, on the emptying and shrinking of the bladder the parts are sure to be drawn asunder, and the danger of infiltration of urine into the post-pubic cellular tissue is much increased. After dividing the subcutaneous fat, which in some cases may be more than an inch in thickness, we reach and consecutively sever the aponeuroses of the abdominal muscles and the pyramidales, and reach the enlarged and distended bladder.

Lifting this with tenaculum, or, as I prefer, with a stitch of ligature, we puncture it either with a trocar and canula, or simply with the tenotome, afterwards enlarging the opening with a probe-pointed bistoury. In place of a canula of metal some use a glass tube, which, being left in place, is not so rapidly fouled as the rubber or metallic tube. In using the tubes a portion of elastic caoutchouc cloth, or "rubber dam" of the dental profession, may be slipped over the end of the tube, thus making a perfectly cleanly water-tight covering for the parts, between which and the abdomen may be a little lint, and in front of which may be placed an amount of absorbent cotton to retain the urine as it flows. In the cases now before us I used the rubber tubing, which enters the bladder, and then is passed across the iodoformed surface under a pad of cotton bandage around the loin to the urinal bottle, thus draining away all the flow.

The colored man before you, as you will observe, and as you notice from the temperature-chart, has been progressing excellently.

The other, who is an older and less healthy subject, is not doing so well. His urine contained quite a serious amount of albumen; he has contracted kidneys, and his uræmic condition and fluctuating temperature seem to portend a serious termination. He, an older man, and with greatly enlarged prostate, has been subjected to more injury from the attempts at forced catheterization. There is also in this, his urine, discoloration due to blood, which may be from the wounded prostate, and the inflamed and contracted kidney as well.

In supra-pubic cystotomy we need never fear the presence of the fold or pocket of peritoneum, as the more enlarged the bladder is by its enforced distention, the higher rises the peritoneal fold before it, so that it lies above and out of the line of puncture.

Case V.—I now will proceed to excavate and resect the astragalus in the youth who is here etherized before you.

In the case now before you you observe synovitic tenderness, and swelling around the ankle; the jerking, painful contraction of the muscles, which has been explained by Hilton as caused by the same nerves which supply the muscles, also sending filaments to the joints themselves, thus keeping up irritation and motion, which mutually react upon and increase each other indefinitely. I make the same curved incision on the exterior of the right foot, and near to and parallel with the peroneal tendon, as you saw me do a week ago; now I, with blunt knife, elevator, lenticular knife, gouge-forceps, and curette, will scrape, break, crush, and remove all the deteriorated, friable, softened astragalus, avoiding the posterior tibial artery carefully, and, as I bring out the articular smooth surfaces of the astragalus, I know that the disease is entirely removed.

I now pack the wound with iodoform lint, and suture the structures together, excluding the peroneal tendon, with the catgut. A moulded anterior zinc splint, well stuffed with cotton, is placed upon the upper padded surface of the limb. With antiseptic dressings, in a few weeks this youth will most probably recover, with a foot and ankle but very little deformed or impaired in motion.

GONORRHŒA TREATED BY ALKALINE INJECTIONS.—Castallan, of St. Mandrier Hospital, recommends a one-per-cent. solution of sodium bicarbonate for urethral injection, and reports twelve cases successfully treated. His theory is that the bacilli of gonorrhœa can flourish only in an acid medium. He claims that the injection prevents the growth of the bacilli, rapidly reduces the discharge, and diminishes or removes the pain in micturition.—*Medical Press and Circular.*

TRANSLATIONS.

On the Sensibility of the Tympanum in Perceiving the Direction of Sound.—When a sound strikes the ear, we locate its source in that point of the horizon towards which the external opening of the organ happens to be directed at the moment of the most intense auditive sensation, and we exteriorize the sensation, attributing its cause to something exterior to ourselves. We thus acquire at once the notion of exteriority and the direction of the body producing the sound.

How is this result obtained? As regards the knowledge concerning the side by which the sound comes to us, this is furnished by the auditive sensation on the right or the left, and also by the consciousness of the muscular efforts to perceive,—efforts which are made to find the maximum auditive sensation indicating the shortest distance between the source of the sound and the ear which listens. But it was necessary that this effort to perceive should itself be guided: so we find that the sensibility of the skin of the pavilion of the lateral portions of the neck, and of the face, brought into play by the sound-wave, also gives indications as to its direction. This is the opinion of distinguished physiologists, such as Weber, Schneider, and Voltolini. Hartman and others go further; according to them it is to the sensibility of the tympanic membrane that the notion of exteriority of the sensation of sound must be attributed. The cutaneous surface of this septum, being struck by the sonorous current, is said to give the sensation of the shock of the sound-waves, and thus the sentient being is notified of the direction and of the source of the sound. Nobody has denied these allegations; but, like Béclard, many thought that the effort to perceive direction was better explained by the consciousness of the movements of the head and of the body in seeking for the maximum intensity of the sound. Dr. Gellé purposely omits examining the part which the pavilion plays as a screen in this effort to perceive direction, and which has been so well brought into evidence by Küss and M. Duval.

The author was able to study this subject and, he thinks, to resolve the problem on two patients in Professor Charcot's ward. The part which the sensibility of the tympanic membrane plays appears very clear. The first patient was a man suffering from general anæsthesia of the skin, with trembling and want of co-ordination in walking, but whose intellect, as well as his sight and hearing, had remained intact.

The anæsthesia was so perfect that a piece of ice placed in the hollow of the ear produced no sensation whatever; the organ remained likewise insensible to ether-sprays or to the infliction of deep wounds made with the point of a needle. Both drum-heads were touched with a needle while the effect was observed by means of a mirror and a speculum. It was found that the membrane might be touched and pricked without the patient's perceiving the least sensation either of pain or of contact; on both sides the anæsthesia was complete. The patient's audition was good, and he heard and replied perfectly well whether he were spoken to by any one in front of him or behind him. Here, then, was a proper case for the study of the sensibility of the tympanum in the perception of the direction of sound.

Placing himself behind the patient, M. Gellé directed him to close his eyes, and then held his watch within a few inches of his right, and then of his left ear. The patient replied that he heard the ticking, but when asked on which side, he found it impossible to say with his eyes closed. The experiment was repeated several times in the presence of M. Charcot, and always with the same result. It may be permitted to conclude that the sensibility of the tympanum plays a serious part in the effort to perceive the direction of sound. In the ward were found several other patients suffering from general anæsthesia. M. Gellé pursued his inquiries upon them, and found that every time a patient could distinguish on which side the watch was placed the membrane retained its sensibility. It is therefore evident, he concludes, that the sensibility of the tympanum is brought into play by the vibratory current, and out of this grows the sensation of exteriority and that of the direction of the sound.

Muscular Contraction and Animal Heat.—At a recent meeting of the Biological Society, M. Quinquaud described the result of his experiments on muscular contraction and animal heat. It is well known that since the beginning of this century animal heat and muscular contrac-

tion have been carefully studied. Many points still remain obscure: it is therefore desirable to provoke with facility and to vary at will the production of heat in a living being.

Here is an experiment which answers to this desideratum. By the aid of an induced current of which the intensity was determined, the muscles of a dog's leg were stimulated twice every second during three-quarters of an hour. After from five to six minutes' stimulation, the rectal temperature began to rise; the rapidity or slowness of the increase of heat varied within certain limits according to the species of animal. The animal was considerably excited; its respiration increased; from twenty-two a minute it rose to one hundred and twelve and one hundred and twenty; it became irregular after the cessation of the current. The animal was muzzled, but breathed easily through the mouth and nostrils.

M. Quinquaud made another experiment, which is as follows. A dog of twelve kilogrammes, with a rectal temperature of 39.4° Cent. (102.6° Fahr.), was submitted to electrization during thirty-five minutes. After an interval of twenty minutes the thermometer marked 41° (105.8° Fahr.). The respiration was increased to 108 during the electrization, and afterwards the dog was in a panting condition, as it might have been after a long run; the electric stimulation was continued during three-quarters of an hour, but after its cessation the animal continued to pant violently; death ensued two hours after the beginning of the experiment, with a temperature of 42° (107.6° Fahr.). The venous blood on the side which had been subjected to electric stimulation contained 0.70 gramme of glucose; the side which had not been subjected to this influence contained 1.20 grammes of glucose.

In a second experiment, a dog weighing seven kilogrammes, rectal temperature 39.7° (102.9° Fahr.), the muscles of the right leg were submitted to electric stimulation. At the outset the animal passed urine and excrement. This urine was obtained for analysis. Fifteen minutes afterwards the rectal temperature was 41.1° (105.9° Fahr.); twenty-five minutes later it became 41.7° (106.5° Fahr.); the respiration was 112, the agitation moderate; the electric stimulation lasted half an hour; the dog remained in a panting condition during the whole evening, as if it had run in a fierce sun. The experiment was made at 11 A.M.; the next morning the animal had recovered. Venous blood on the side subjected to electric stimulation contained 0.75 gramme of glucose; on the other side 1.15 grammes of glucose.

The third experiment was on a dog weighing six kilogrammes, which had been already subjected to several electrizations, with a normal rectal temperature of 39.5° (102.7° Fahr.). At 10.38 A.M. the electrization was begun, and at 10.48 the rectal temperature was 39.9° (103.1° Fahr.); at 11.2, 40.1° (104.1° Fahr.); at 11.35, 40.7° (104.7° Fahr.); and at 12 o'clock, 41.4° (106.2° Fahr.). In this experiment the increase of heat was slow; the temperature increased progressively, as in the other experiments; the animal remained in a panting condition for seven or eight hours, and ended by recovering itself; but if the experiment had been continued, it would doubtless have succumbed.

These experiments are interesting by virtue of the following considerations. It is curious to see a localized muscular electrization engender a condition of general hyperthermia; the possible cessation of life some time after electrization; death resulting partly from the increased heat; the greater destruction of saccharine matter on the side where the artificial muscular contractions were produced; and the possible therapeutic applications in cases of refrigeration. It is an experiment easily repeated.

M. Quinquaud, at a future meeting of the Biological Society, will indicate the disturbances caused in the different functions of the organism and the mechanism of death.

PERILS OF SCHOOL-LIFE.—M. Lagneau presented to the Academy of Medicine a report upon cramming of young children at school and the evils which it has in train, and concluded by declaring that the "Academy of Medicine calls attention of the public authorities, the Ministers of Public Instruction, of War, and of the Navy, to the utility of opposing the intellectual cramming and sedentary life in schools, and to the necessity of modifying the course of instruction so as not to burden the minds of young children."—*La France Médicale.*

EDITORIAL.

SEA-AIR AND SEA-BATHING.

AS, year by year, the popularity of our sea-side resorts steadily increases, the problem of how to get the most benefit to health from a visit to the sea-shore becomes of more general interest. It is quite evident, from the habits of the people, that public opinion has not as yet crystallized upon this subject. It would be a matter of surprise, were it not one of common observation, that, among those who leave home in ordinary health to spend a few weeks in recreation at the shore, attacks of sickness are so common. In a small hotel it was recently noticed by an odd coincidence that seventy persons were sick at one time with diarrhœa or symptoms of summer cholera. In the case referred to, as in most summer-resorts with any claims to respectability at the present day, due attention had been paid to the drainage and water-supply. Moreover, the fact that the disorder referred to was not confined to one locality, but was general, points to a wide-spread cause. It is customary to ascribe such attacks to bad drainage, since so many sad illustrations have been furnished of disease and death due to criminal negligence of sanitary precautions; but attention has been directed to this with such force and persistency that a better state of affairs has been brought about, and most American summer hotels may now with reason be termed health-resorts.

A potent cause of such attacks at present seems to be in the habits of the people. The association of a large number of persons, like Mr. Gilpin, "on pleasure bent," inevitably leads to a constant round of excitement, which affects the equilibrium of the nervous system and reflexly tends to impair nutrition. The change of air and scene stimulates the appetite, while the abundance and variety of the fare tempt to over-indulgence at the table. Bathing is often undertaken too soon after eating. In consequence, digestion is interfered with, the blood is driven from the periphery to the internal organs, and the mine is laid for an attack of acute gastro-intestinal indigestion, with prostration, vomiting, and purging,—making a colorable imitation of an attack of cholera morbus. Moreover, bathing, fishing, and crabbing, often with both the direct and reflected rays of the sun beating upon the unprotected head and shoulders, may cause a severe meningeal congestion, or possibly sunstroke, particularly if there has been, as is very often the case, more or less indulgence in alcohol.

The active factors in the use of baths at the sea-side are summed up by Leichtenstern as follows: 1, the cold bath; 2, the salt contents of the water; 3, the motion of the water and the force of the waves; and, 4, the important factor of sea-air. As the cold baths cause a propulsion of blood to the internal organs, they should not be used by persons subject to hemorrhages of any kind: this explains the tendency to attacks of apoplexy during or after the bath. Very anæmic and lean persons do not bear cold baths well, on account of their deficient heat-making power. Such persons are much benefited by the heated sea-water baths, or by sponge-baths. In anæmic subjects with a good supply of fat, suffering with irritable weakness or nervous dyspepsia, the sea-baths are decidedly curative; as they are also in scrofulosis of the pasty types. Patients suffering with nervous disorders of various kinds have received much benefit from sea-bathing; but it is doubtful if greater benefit be not obtained from the climato-therapeutic effect of staying at the sea-side. Consumptives of a nervous type

sometimes are greatly improved by the climatic influence; but if there is a decided catarrhal element present in the case, dyspnœa may be caused by the dampness of the air. Such cases should not be sent to the sea-shore, but to the mountains. Whether sea-bathing is permissible in pregnancy or not is dependent entirely upon circumstances,—the force of the waves, the temperature of the water, and the personal equation,—and no rule can be laid down other than the general principle that proper caution should be observed to prevent shocks or violent exercise.

In order to obtain the most advantage to health from a visit to the sea-shore, we would advise that the advantage of obtaining good rest at night, as a result of the comparative coolness and the sleep-inviting air, should be more highly appreciated, and that a regular hour for retiring be observed. A light breakfast, with little, if any, meat, is a good beginning for the day. Bathing should be undertaken only after a sufficient time has elapsed for the digestion of the last meal,—this would require probably at least three hours,—and at first the duration of the bath should not exceed twenty or thirty minutes. It would be advisable for those who are not very strong to postpone the sea-bath for several days or even weeks after their arrival, and confine themselves to warm baths or sponge-baths. It would certainly be wiser for invalids who resort to sea-bathing as a therapeutic measure to do so only under medical advice.*

Those who are wise enough to lead a well-regulated life at the shore will, with few exceptions, derive vigor and increased powers of resistance to disease from their vacation; those who are irregular and careless will generally return in poorer physical condition than when they left home, and with the conviction that the sea-shore does not agree with them.

* A litt'e book by Dr. Packard, of this city, contains much useful information upon this subject. It is entitled "Sea-Air and Sea-Bathing." Published by Blakiston, Philadelphia, 1880.

THE TREATMENT OF CONTRACTED KIDNEY.

DROPSY no longer claims a place among diseases in our text-books, as it did in those of a preceding generation of physicians, the attention of the modern therapeutist being directed to the physical causes of this condition, and his skill is shown by his well-directed attempts to correct the disorder of the circulation which gives rise to the anasarca and serous effusions. In the management of that large class of cases in which crippled kidneys play a prominent rôle, it has been found by experience, moreover, that hygienic and sanitary considerations are relatively more important than the selection of particular remedies which have been thought to be more or less "indicated" by the disease.

Nothnagel, in a recent clinical lecture,† has pointedly directed attention to the fact that of the remedies made use of in *morbus Brightii* a great portion is given quite uselessly. In particular does he advise caution in the use of digitalis in contracted kidney, since an injudicious increase of pressure in the arterial system may produce rupture and cerebral hemorrhage. The therapeutics of chronic contracted kidney with granular atrophy is limited to intelligent dietetic measures, the leading principle of which should be to maintain normal diuresis. Since diuresis partially depends upon the tension of the artery, the cardiac functions must be carefully watched, and all those measures taken which are observed in cases of valvular disease of the heart. Excessive exercise, undue indulgence in alcoholic drinks, coffee, tea, or hot beverages, and emotional excitement, are to be forbidden. If the cardiac activity be reduced so that arterial

† On the Treatment of Nephritis. *Medical Press and Circular*, June 29, 1887.

tension is below normal, even though hypertrophy of the ventricles may exist, cardiac stimulants may be used, the most efficient of which is digitalis, which, after the caution already given, is understood to be a two-edged sword and employed only with circumspection. A milk diet, and suitable clothing, and residence in a warm equable climate, have been sufficiently dwelt upon by modern writers. If exercise bring about a marked increase of albuminuria it may be necessary to confine patients to their room. Bartels has had good results from restricting the patients to their beds for weeks or months. Subsequently, attention to maintaining the function of the skin by baths, massage, and warm clothing is most useful. If there be marked dropsical effusion, the use of pilocarpin and hot air baths is to be resorted to, with the classical diuretics (squill, digitalis, and potassium salts), to which calomel has been recently added by Jendrassik, who has directed attention to its decided diuretic effect, but it is liable to produce stomatitis and diarrhœa unless carefully watched. By the adoption of these means the prognosis of contracted kidney may be decidedly improved.

HOT WEATHER DRINKS.

VERY diverse views are held as to whether ice-water is wholesome in hot weather; or how much of it may be safely taken at once. Some avoid it *in toto*, and others swallow it wholesale. The first are apt to fall back upon beer, and the last are prone to cholera morbus. As in most other affairs of life, a happy medium is the true solution. Ice-water is good to drink, and it is by far the best assuager of thirst to be had in this torrid condition of both town and country; and although good beer in moderation may be serviceable in allaying thirst, it will never satisfy the longing for inward refrigeration so promptly or so safely as will cold water in reasonable amount. We no longer withhold ice-water from our fever patients, nor should we deny it to those who are in a feverish condition.

Acidulated beverages, such as lemonade or acid phosphate, with or without a pinch of cream of tartar, are alike pleasant and efficacious in allaying thirst and in keeping the kidneys active,—an important matter at all times, but specially so when people *will* eat as heartily of animal food in midsummer as in winter.

Good buttermilk takes the place nicely of the long line of "cocktails," "juleps," and the like, too often deemed necessary for the comfort of young men, while for children and their nurses it is both meat and drink during the hot weeks of summer.

NOTES FROM SPECIAL CORRESPONDENTS.

PARIS.

TREATMENT of Abortion in Paris.—Having followed the methods used in the hospitals here, and attended the recent discussion at the Société Obstétricale de Paris, we can give a few interesting points with regard to the system used here, where abortion is so frequent that Professor Tarnier says that it exists in one out of every four pregnancies.

First, as to its preventive treatment. The rule given is, "As long as an abortion is not completed,—that is, the products of conception expelled,—attempt may be made to prevent it." This is not a rigid rule, however, for certain cases are inevitable: as, for instance, when the fœtus is dead. When the membranes are broken and the amniotic fluid has escaped, it is almost inevitable, but not certainly so; because several cases are known where the fœtus has been carried to term when the waters had been lost weeks before. There is no reason to consider an abortion inevitable because there is a hemorrhage, and even when in the blood discharged one can recognize portions of the decidua, for pregnancy has been proved to have gone on without it. Even when the os uteri is dilated and a portion of the embryo protrudes, hope may still exist.

The preventive treatment can be summed up in two formulæ: 1st, require absolute rest, with dorsal decubitus in bed, *never on the sofa;* 2d, diminish the uterine irritability by opium. Laudanum may be given by rectal injections. Twenty drops are first tried in

one-quarter pint of water; this is increased to forty, fifty, sixty, and up to a hundred drops in the same quantity of water per twenty-four hours. Pregnant women possess considerable tolerance for opium, and hypodermic injections of morphine may also be given when rapid action is needed. The above simple treatment is all that is used here, anæsthetics and chloral not being in favor.

When the abortion is inevitable the treatment is different. It must be divided into the treatment of an abortion of the first eight weeks and those of the third and fourth months. As to the first, the indication is to fight the hemorrhage, and the simplest treatment is the best. It mostly consists of absolute repose and expectation, and there is a good deal more to say as to what ought not to be done than what ought to be done. As to the first, one ought *never* to use applications of perchloride of iron on cotton in the vagina, on account of the blood forming clots which are difficult to detach, and which may cause septicæmia, or at least complications such as metritis or perimetritis. As to ergot, all the Paris accoucheurs have made a rule never to give it as long as anything remains in the uterus. As to the other forms of internal medication, they are considered worse than useless. There is therefore but very little done except to keep up perfect antisepsis. Every four hours an injection is made into the vagina of a solution of boric acid (three or four per cent.) or corrosive sublimate (one to three thousand). Besides this, the vulva is covered with borated cotton (the only dressing used at the maternities here); carbolized cotton is likely to produce burns that are very painful to delicate skins. When the hemorrhage is very severe, the means used are two: first, injections of hot water (intra-uterine if the vaginal are not sufficient). These are made with sublimate as a rule, unless this produces diarrhœa symptoms, when it is changed to carbolic acid solutions. One part of corrosive sublimate to six thousand of water is usually enough, unless there is danger of septic infection; then as much as one to two thousand is used. The temperature should be 43° or 44° Centigrade. If the vulva become painful from irritation of the liquid, use the following application: vaseline, one hundred grammes; boric acid, ten grammes. Have the boric acid well pulverized and well rubbed, or it will form hard lumps in places. If the flooding still continues, the only means left is to use the tampon invented by Leroux, of Dijon. In using the vaginal tampon, many have no idea of the quantity of material that should be prepared beforehand. Professor Pajot used to say, "Remember to have as much as would fill a high hat," and this is no exaggeration at all. Some twenty to thirty large lumps of sublimated cotton are prepared, each one tied with a long piece of string, and one by one are introduced, filling the vaginal cavity until it extends back to the ischium. It must not be forgotten to be sure to have the bladder and rectum empty before commencing. The tampon is never allowed to remain for more than twelve hours.

Massage.—This subject is again the order of the day, and several surgeons, as well as the strictly medical men, are bringing the matter forward. Dr. Dujardin-Beaumetz gives some interesting details of its history. It was known to the ancients, having been spoken of in an old Chinese work called *Cong-fou*. In India it has been practised for ages, and they call it *chemboo*, from which we get our word "shampoo." The Greeks and Romans made much use of it. It is curious to cite a remark of Hippocrates in regard to a woman who had a hardness of the abdomen. He said, "It was violently kneaded with the hands covered with oil, and cured." It can be divided into two kinds: massage with apparatus and without. Four kinds of action are used. First, *effleurage* (to skim over). This consists in light passes of the hand, or only the fingers, over the part; it is what the Germans call "combing the flesh." Next is friction proper. Thirdly, *pétrissage* (kneading). This is done by raising up certain muscles and rolling them together, or else kneading them with both hands. The last form is called *tapotement* (to pat or slap gently). Here there is a division made into slapping gently the tissues or striking (*hachement*) them with the ulnar border of the hand. Not much importance is given to the various oils and fats used with the massage. A story is told of a quack who had a sure cure for hernia, which consisted of a certain secret pomade he sold; the point lying in the directions given, which consist of massage and a good bandage put on after the pomade is used. In honest practice vaseline is often used, more or less perfumed with drugs, which have but little to do with the success.

As to the applications of massage in surgery, all surgeons are now agreed that it is the best form of treatment for all sorts of sprain, but as to fractures there is a division of opinion. M. Marc Sée and some others are highly in favor of it, while Trélat is opposed to it. The point seems to be that it should be applied at once to be of use,—just as soon as the patient is seen,—and, if the fracture is open, it is not to be used at all, at least until the wound is perfectly healed. In gynæcology and obstetrics its practice is very restricted here. In all articular affections good results are obtained. As to massage in the neuroses, it has as yet but few partisans in France. In heart-disorders much is done to reduce œdema, and the same good results are obtained in constipation and dilatation of the stomach. It is almost certain that all the good effects of Aix-les-Bains are owing to the skilful use of massage, for the waters themselves are but slightly

mineralized. There the *masseurs* have their art handed down to them from father to son, and mother to daughter, for many generations back, and it requires this great experience. Before modern establishments make a success of massage, they must consent to study it as other arts are studied, and give a certain time of apprenticeship to it if they hope for much success.

Intellectual Overwork and Sedentary Life in Schools.—The Paris Academy of Medicine has been making some long and rather tall talk over this subject. It has perhaps been overdone, but the evil certainly exists. Dr. Brouardel said that, in his opinion, students did not only lose their health from too much work and sedentary life, but also from the very conditions of life in large cities. When they are young, boys in the large towns are extra bright; but let a few years go by, and, if they are called upon to do much intellectual work, we see that they fall away and end by an arrest of development of intellect as well as physique. In many of these cases the genital organs do not develop, and these young men resemble, both in the abdominal region as well as the thoracic, young women of the same age. They are a sort of reproduction of the fabled Ganymede; and this anatomical state is definite. They do not change much as they grow older. At first at school they astonish their families by the great aptitude they have for study; but as puberty approaches a great change takes place, and they generally take the downward road to arrive at nothing of importance. Dr. Brouardel spoke against the custom here of placing boys in boarding-schools and keeping them confined so closely. If such institutions must exist, let them be placed out of town, where the boys could be exercised in the pure air of the woods, and not by a melancholy walk about town. There is nothing more curious in Paris to an Anglo-American eye than the sight of the long strings of boys in a tight uniform coat of the college they belong to, walking slowly along, two by two, as demure as girls out with their mammas.

Professor Peter spoke in a later session this month, on the same subject, and called attention to the symptoms, particularly of headache, from overwork in intellectual pursuits. He said that it was a much-neglected symptom that might lead to pathological disaster more quickly than usually thought. It was the cry of the overworked brain, the voice of suffering of an organ fatigued that demanded rest. If this cry were not heeded, the brain would refuse to perform its usual functions, and the cerebral cells would go on a strike. Many of these young overworked children complain of headache, and are told that it is laziness; but it will reproduce itself the moment any reading or study is attempted. It is a sort of, writer's cramp of the brain. M. Peter spoke of cases where the young subjects could take part in conversation, but the moment they went to books the headache returns, and very often with epistaxis. To this, later on, is added a sort of fever. A typical case is given of a young girl. The mother relates the case: "My daughter was nearly at the end of her studies for a diploma when she was taken with violent headache and bleeding of the nose, which was soon afterwards followed by fever; both her appetite and sleep soon left her. The family doctor suspected typhoid fever, and at once ordered rest; but for some time the symptoms returned. The superintendent of the school said that it often happened that her students had these symptoms, and she stated that four months of holiday was the only cure. In some cases over three years was required to re-establish them." M. Peter spoke in strong terms, condemning the close confined air of schools and the action it had in producing tuberculosis.

Hydrophobia.—Monsieur Pasteur having returned to Paris, it was expected that something would be done at the Academy in regard to the opposition made to his treatment by Professor Peter and others, and M. Pasteur took the opportunity in the last session to lay before his fellow-scientists a report of the commission appointed by the English Parliament to examine into his treatment of hydrophobia. As perhaps many of your readers will have seen, this report was quite favorable to the Pasteurian treatment, and M. Pasteur and those with him rejoiced over this fact in presenting the report.

Professor Peter, however, returned to the charge by stating that in January last he took occasion to direct attention to the danger of the form of intensive treatment then employed by M. Pasteur. He understood that since then it had been very much modified, and that now they do not dare to inoculate with three-day-old marrows; but, notwithstanding that there was a return to the first system, it seemed to him that it was just as inefficacious as ever. He presented as proof of what he said the case of a man named Hurot, who was bitten by a dog on the 29th of May last, who went at once to the nearest drug-store, where he had the slight wound carefully cauterized. Owing to the advice of some friends, he went to the Pasteur Institute the day afterwards, where in thirteen days he was inoculated eighteen times. Following this he went to his work, and felt no trouble of any kind until about ten days ago, when he was suddenly taken with a curious malady. Dr. Miquel being called, he recognized all the usual symptoms of hydrophobia, and sent the man to the St. Antoine Hospital, where he came under the care of Professor Hayem, and where he died in frightful agony. M. Peter called attention to the fact that the

incubation of hydrophobia was about thirty-five days, and that it was exactly this time since the man was inoculated, and he did not hesitate to say that it might be from the treatment followed by M. Pasteur.

M. Pasteur answered that his system was established in many places, and that it was confirmed by the English commission, and to prove that a man had died by it it would be necessary to inoculate animals with his medulla oblongata; but this proof was not given in any case. He said he did not wish to discuss the question with the person who just spoke (Professor Peter), as he did not think him clinically or experimentally competent.

Professor Peter answered that no one is incompetent who cited facts, and he wished to continue his argument, but was put off until the next meeting of the Academy. It is very difficult to judge of M. Pasteur's treatment, and whether he or M. Peter is right; but it will not take any one long to judge of the competency of Professor Peter to discuss any clinical matter much better than the eminent chemist who so carelessly denies his competency. M. Pasteur will not gain any friends to his method by this kind of talk, and will most likely regret having spoken as he did at this session, when he will again be sharply attacked by the great clinical master next week.

Ablation of the Ovaries for Nervous Disorders.—This question has just been brought before the Gynæcological Society by a paper presented by M. Lucas Championnière. There are three principal points in regard to it: 1st. Is there a relation of cause to effect between ovulation and menstruation? 2d. What is the prognosis of the operation? 3d. Is ablation of the ovaries, when they are healthy or diseased, to be authorized in nervous diseases?

1st. There are three different theories in regard to ovulation and menstruation: (*a*) that ovulation is under the dependence of menstruation; (*b*) that menstruation is under the dependence of ovulation; (*c*) that they are both under the dependence of the central nervous system. No matter what may be our opinion, there are certain facts that must be admitted. Menstruation is a function that has a periodical return, and ovulation does not of necessity follow it; it is independent of menstruation. This is based on clinical and anatomical facts. Leopold's work is based on the examination of ovaries taken from women who died during their menstrual periods, and he saw that he could always find Graafian follicles about to break or else already broken. The same observation was made by Lawson Tait, who operated between the monthly periods. M. Porak has given twenty-one observations where a single coitus was followed by conception; four times he could not get any information about the time; twice the connection took place near to the monthly term; but in the other fifteen cases it took place during various periods of the month; so that conception can take place at any time between the periods. The Jews, who are so prolific, separate from their wives during the eight days following menstruation. What, then, are the arguments worth which are given to support the idea that ovulation and menstruation take place at the same moment? A comparison is made in regard to the rut of animals; but this is only a hypothesis, for we do not know if any one has really seen the rupture of De Graaf's follicle during menstruation.

It is concluded then that ovulation is a permanent function, and menstruation a periodical one. It is not intended to say, however, that there is no connection between them, but that they are not dependent on one another. Does ablation of the ovaries cause menopause? Not always; but it does as a rule. Hegar thinks it does; Goodman is not so sure. M. Championnière, with most of the French surgeons, believes that in cases where the menopause does not occur all the ovarian tissues were not taken away in the operation. The final question is, Whether this operation ought to be done for nervous complaints or not? It has been proposed for certain forms of dysmenorrhœa, and for nymphomania. The solution of this question reposes on two things: first, the prognosis of the ablation; second, the amelioration of the nervous affection. M. Championnière mentions one death in three operations, which is not at all encouraging. He also cites Magnin's paper, containing seventy-seven cases with three deaths, but his statistics are not correct. Hegar gives sixteen per cent. Lawson Tait had twenty-five per cent. of deaths; but afterwards made one hundred and eight ablations with two deaths. Goodell in 1885 gave twenty-five cases and only one death. In any case it is a serious operation, and we must ask the question, What are the results? In nymphomania none. In hysteria a slight amelioration, but in general the results are negatives. Hysteria is certainly an affection of the central nervous system, and not at all dependent on menstruation. In dysmenorrhœa cure is often obtained, but there are cases that are only aggravated. In fact, this operation is one that should not be practised until all other means had been tried, and it is the opinion of many of our best obstetricians that many cases will be cured in time from more simple treatment than this extremely grave operation.

Preservation of Cadavers.—M. Bouchard, of Bordeaux, gives a new means of preserving dead bodies for anatomical use. He found that, owing to the warm climate of Bordeaux, they had more difficulty than else-

where, and made many experiments to improve the methods used, with the result of finding one that acts very well; so much so that they were able to keep subjects for two months without the slightest signs of putrefaction or smell of any kind. The muscles and tissues keep their normal color and consistence, and the anatomical elements are not altered. Every one knows how the nervous centres get soft and useless for the purposes of study; but with the present preparation it has been possible to extract firm brains after three weeks' preservation of the body. The following is the formula used: borate of soda (which is hydrated to ten equivalents of water), ten kilos; to this add seventeen kilos of glycerin at 30° Baumé. The materials must be of the best quality, and they are prepared as follows: 1st. Reduce the borate of soda into a fine powder, and pass it through a sieve, No. 0. 2d. Put it into a large receptacle, and mix in the glycerin slowly to prevent lumping. 3d. Heat all up to a temperature of 80° Centigrade until the borax is dissolved; it should be constantly stirred. 4th. Pass it through a flannel sieve. The liquid will be now in a syrup, and it must be thinned with alcohol in order to inject it. The injection is made by the carotid or the femoral. If in this last, be careful to inject below the origin of the profunda femoris. For all subjects that have had an autopsy made, inject the members and plunge the trunk into a bath of the alcoholized, borated glycerin for twenty hours. Since using this method, M. Bouchard says that the students who cut themselves do not experience any symptoms of poisoning, and besides they do not any longer suffer with gastro-intestinal affections.

Strophanthus hispidus.—Since Fraser spoke of this medicine a good deal has been said about it, but so far the experiments made with it have been restricted here, owing to the high price first charged for the drug, and also owing to the fact that such men as Professor Germain Sée and others wanted to get the alkaloid. M. Hardy, of the Hôtel-Dieu laboratory, has made a little of it, but it is too soon to speak with certainty of the results of the experiments at that hospital in M. G. Sée's service. The plant, it seems, was first brought to Europe by Livingstone in 1865. The solution in water, one to one thousand, was tried in subcutaneous injections, but it produced a serious inflammation of the skin, and its use was abandoned. The best preparation we have been able to get so far is the alcoholic tincture, which is given three times a day in five-drop doses. In all troubles consecutive to the affections (primitive or secondary) of the heart-muscle, strophanthus has been pronounced a great success. The pulse gets fuller and stronger; its frequency is diminished from twelve to forty pulsations per minute; respiration becomes more quieted, more profound, and less rapid; diuresis augments to sometimes six or eight times as much as before its use. The action is durable and persistent, keeping up so far for three or four months. The medicine seems to be particularly useful in Bright's disease, being preferable to digitalis here, as it raises the amount of urine without increasing the blood-tension, as digitalis does. It does not seem to have any action over fever at all; but the patients get better quicker under its use, and do not seem so depressed. Later we will be able to give more definite results as soon as the alkaloid (strophantine) itself comes into use.

Wounds of the Intestine by Firearms.—The Paris Surgical Society this winter had a considerable discussion over this subject, and Professor Trélat with others took up what may be called the American mode of treatment. This has been very ably put forward in a thesis just presented for the *doctorate* at the Faculty here by an English physician, Dr. J. H. Barnard, who kindly forwards us a copy of his work. He cites the opinions of Gross, Hamilton, Bull, Otis, Nancrede, T. G. Morton, and others, and concludes that opium treatment with expectation is useless; and that the moment we are brought into consultation with such cases we must at once make preparations to perform laparotomy on the median line (*linea alba*); and that the operation has the more chance of success the quicker it is done. He says that, according to Morton, the lapse of time when the operation was successful was seven hours, but those without success over twenty-three hours. This matter is so essentially American in its treatment that nothing more need be quoted to your readers from this interesting thesis.

THOMAS LINN, M.D.

PARIS, July 8, 1887.

PROCEEDINGS OF SOCIETIES.

AMERICAN CLIMATOLOGICAL ASSOCIATION.

THE Fourth Annual Meeting of the Association was held in the Johns Hopkins University, Baltimore, Maryland, May 31 and June 1, 1887, the President, Dr. Frank Donaldson, Sr., of Baltimore, in the chair. The President's Address was on the subject of the

PROPHYLACTIC TREATMENT OF THOSE WHO INHERIT A PREDISPOSITION TO PHTHISIS.

The great mortality of phthisis is well known, but statistics lately compiled show a decrease in the annual mortality both in this country and abroad. In Massachusetts there has been a gain of fifty-four lives per one hundred thousand. It has been shown that thirty per cent. of the cases have an inherited

predisposition, and this hereditary form, when developed, offers the least prospect of recovery. Nearly all observers have now accepted the views of Koch. There is abundant evidence that human subjects readily yield to the bacillar poison when previously they have been in perfect health. This bacillus is always present in phthisis, and we must accept it as the full explanation of the manifestations of tuberculosis. The disease may be propagated by the inhalation of the dried bacillus from the expectoration of diseased persons by persons predisposed to tuberculosis. The prophylactic treatment embraces two elements: (1) the improvement of the general health of the subject, and (2) the protection from contagion. Tuberculous mothers should not nurse. If possible, the child should be given to a healthy wet-nurse. The hygiene of the nursery should be looked after carefully. The room should be well ventilated and kept at a comparatively low temperature. The subject should live much out of doors, especially between the ages of fifteen and twenty years. The beneficial influence of sunlight should be borne in mind. All causes of glandular irritation should be avoided. Scrofulous glands should be dispersed or removed. The physical form of the chest should be enlarged by gymnastic movements. If possible, life should be passed in a high altitude. Oleaginous fluids are useful if they can be digested. The milk and flesh of tuberculous animals must be avoided, for cooking rarely destroys the bacilli of beef. If the prophylactic treatment is thoroughly carried out, the hereditary proclivity may remain latent permanently.

DISCUSSION.

Dr. James C. Wilson, of Philadelphia, endorsed the view that pulmonary tuberculosis in all its forms is in all probability an infectious parasitic disease directly contagious.

Dr. B. F. Westbrook, Brooklyn: The anatomical and physiological conditions which predispose to this disease are, according to the results of observations, a disproportion between the size of the heart and the lungs, the heart being smaller in proportion to the size of the lung than in the ordinary individual, and a disproportionately small digestive apparatus. The former condition interferes with the circulation at the apices, while the latter condition causes a defective nutrition.

THE PHILOSOPHY OF CLIMATIC TREATMENT OF DISEASES OF THE CHEST. BY JAMES R. LEAMING, M.D., OF NEW YORK.

It is observed that during the first three weeks of the patient's stay at a new place the greatest improvement usually takes place. The suggestion was made that a line of resorts be established along the Atlantic seacoast. The patient could begin in the summer at the most northern and gradually pass southward, making a stay of a few weeks at each place. Having completed the series, the patient may return, taking the stopping-places in a reverse order. This same plan might be applied to the Pacific coast and to the mountains. The speaker also suggested the propriety of State and municipal authorities furnishing sanitariums for the poor.

THE INFLUENCE OF SEA-AIR ON SYPHILITIC PHTHISIS. BY DR. R. G. CURTIN, OF PHILADELPHIA.

The histories of five cases of what appeared to be syphilitic phthisis, in which improvement followed prolonged sea-voyages, and in each case of which the symptoms returned when the patient again took up his residence on land, formed the basis of this paper. He considered the cases observed as cases of syphilitic phthisis for the reasons that there were no symptoms of chronic pneumonia preceding the attack, that the lung-disease followed syphilitic infection with constitutional symptoms, that the disease was influenced to some extent by constitutional treatment, and that there was no tendency to tuberculosis in these cases. He referred to the observations of Dr. William Porter, who relies upon the following points in reaching a diagnosis of syphilitic phthisis: 1, abundant expectoration without signs of softening; 2, a debilitated condition without marked emaciation and a rational history of phthisis; 3, pronounced dyspnœa without evidence of cardiac or pulmonic obstruction to the circulation; 4, pain along the sternum and the tibial crests; and, 5, the satisfactory response to treatment. Dr. Porter had examined the sputa in one hundred cases without finding the bacillus. The speaker was not prepared to say why it was that the sea-air proved beneficial in these cases, contrary to experience in the ordinary cases of phthisis.

A paper by Boardman Read, M.D., of Atlantic City, on

DISEASED CONDITIONS FOR WHICH SEA-AIR IS OF DOUBTFUL BENEFIT,

was read by title.

A general discussion followed.

Dr. James C. Wilson, of Philadelphia, said that there are three classes of patients with consumption who cannot go to our exposed Atlantic sea-coast without risk. These are—first, those in whom there is active febrile disturbance; secondly, those of a highly excitable and nervous organization; and, thirdly, those who suffer from repeated attacks of spitting of blood.

Dr. Frederick C. Shattuck, of Boston: The author has referred to syphilitic phthisis,—that is to say, a destructive process in the lung not due to tubercle, but to the syphilitic

virus. It seems to be a difficult matter to determine whether or not there is such an affection. Tubercular phthisis varies so much in its symptoms that the points mentioned cannot be relied on. It seems that the criterion would be the presence or absence of the tubercle-bacillus. The author referred to Dr. Porter as having examined the sputa from one hundred cases of supposed syphilitic phthisis without finding the bacillus. That number is so large for the short time that this test has been available that it would make us a little doubtful of the methods employed. The fact that the bacillus is not found is no proof that it is not present. The German Committee on the Collective Investigation of Disease studied this matter last year and came to the conclusion that so-called syphilitic phthisis had no real existence. Both syphilis and tuberculosis are common diseases, and the one offers no immunity from the other, so that we should expect to frequently find them combined in the same individual.

Dr. J. H. Musser, of Philadelphia, said that he had never seen a case of phthisis which he considered of syphilitic origin. In the post-mortem room he had come across only one case in which the lesions bore any resemblance to what we should expect to find in syphilitic phthisis. This was the case of a young man with syphilis and cirrhosis of the liver due to syphilitic interstitial hepatitis. There were also syphilitic gumma in the brain, and the patient died of syphilitic meningitis. There were scattered through both lungs innumerable miliary granules not at all resembling miliary tubercles. These were solid bodies made up of a yellow core, which was moderately firm and surrounded by a ring which made up at least one-half of the nodule. The microscopical examination showed these bodies to consist of a ring of firm fibrous connective tissue, in the centre of which there were degenerating cells. We were unable to find the bacillus of phthisis, but, as has already been stated, the failure to find it is no proof of its absence. He would not call this a case of syphilitic phthisis, but rather a case of syphilis of the lungs.

Dr. E. Fletcher Ingalls, of Chicago: I have been much interested in the remarks of the gentleman from Boston, but I apprehend that most of us had seen cases in which the syphilitic nature of the disease admitted of no question. Even if the bacilli are found, it would be no proof that the case had not originated as a syphilitic disorder and that it had subsequently become tubercular.

THE TREATMENT OF THE FINAL STAGE OF PHTHISIS. BY DR. J. H. MUSSER, OF PHILADELPHIA.

This contribution consisted of a detailed account of the symptoms met with in the last stages of phthisis, and referred to the various measures which he had found useful in these cases. To relieve the high temperature he had resorted to antifebrin with advantage. Quinine was found to act unsatisfactorily.

In the evening a paper entitled

CAUSES OF CARDIAC FAILURE IN HIGH ALTITUDES

was read by Dr. Frank Donaldson, of Baltimore.

The important fact that there is often great dyspnœa and sudden cardiac failure on going to high altitudes has not been sufficiently emphasized. Many patients are sent for general or special reasons to high altitudes, and are thereby done great injury, especially if they suffer from any form of functional or organic heart-disease. From some experiments with the pneumatic cabinet the author had come to the conclusion that this treatment should not be employed in cases in which there is any valvular disease of the heart or fatty degeneration of its walls. Before being subjected to treatment in the cabinet, an examination of the heart should always be made. It has been asserted that the cause of the cardiac failure in ascending to high altitudes is want of oxygen. The speaker had performed certain experiments with reference to this point. At altitudes within ten thousand feet there is sufficient oxygen to supply the hæmoglobin. In ascending to high altitudes the pressure of the air within and without the lungs is the same, but on the heart the action is different. The pressure is removed from the outer surface of the heart, while the internal blood-pressure remains the same. There consequently must be dilatation of the heart-walls. This, in the author's opinion, was the cause of the heart-failure under these circumstances.

DISCUSSION.

Dr. B. F. Westbrook, of Brooklyn: I have no doubt that the explanation of the author with reference to the effect of high altitudes on the heart is correct, but in the pneumatic cabinet the conditions are different. Where the patient inhales compressed air or sits in a rarefied atmosphere and inhales air at the ordinary pressure, there is an absolute or relative increase of pressure within the thorax. The heart is, therefore, submitted to a relatively increased pressure. As a matter of practical experience, he had found that patients with mitral stenosis or mitral regurgitation with pulmonary congestion can be put in the cabinet with safety. He should hesitate very much before putting a patient with aortic regurgitation into the pneumatic cabinet. In mitral disease, however, the tendency is to assist rather than exhaust the diseased heart.

Dr. H. F. Williams, of Brooklyn: Certain New York observers have claimed that in weak heart, particularly the "tobacco heart," they have obtained with the pneumatic cabinet an

effect similar to that of digitalis, due probably to a stimulation of the circulation through the coronary arteries.

Dr. S. S. Cohen, of Philadelphia: The heart is habituated to a certain pressure of the atmosphere (seven hundred and fifty-four millimetres of mercury). When the individual goes into a rarer atmosphere there is a disturbance of the relationship between external and internal pressure, and this disturbance will necessarily bring disease upon the patient. The inhalation of compressed air in cases of dilated heart has been recommended for many years by Waldenburg and others. He had recently employed this measure with beneficial results in alleviating the dyspnœa and defective circulation due to a dilated heart.

Dr. James T. Whittaker, of Cincinnati, Ohio: The condition met with in a rarefied atmosphere cannot be compared with that met with in the pneumatic cabinet. It does not seem possible to exert any mechanical pressure upon the heart in the cabinet. The conditions which have been observed admit of easier explanation by a study of the effects on the surface vessels. When the pressure is removed from the superficial vessels, the dilated heart propels the blood easier than before. This is one of the most efficacious means of treating irregular heart. He had used the cabinet for two years and had seen no ill effects from its use, although patients with advanced cardiac disease should not be subjected to this plan of treatment.

SOME HOSPITAL CASES OF PHTHISIS—MARKED IMPROVEMENT UNDER GENERAL TREATMENT, WITH SPECIAL REFERENCE TO ALIMENTATION. BY DR. F. C. SHATTUCK, OF BOSTON.

The cases reported in the paper had been treated in the Good Samaritan Hospital, devoted to the care of chronic diseases. Many of the patients had previously been exposed to unfavorable hygienic surroundings. The principal object of the treatment was the improvement of the general condition. Search had been made for a specific treatment. If the disease is of a parasitic nature, it is natural to suppose that such a treatment would be of avail. At present no such method of treatment is known. There are few individuals to whose lungs, at one time or another, the bacillus does not gain access. The fact that certain individuals are affected while others escape forces us to believe that there is a predisposition to the disease. The treatment employed by the author had consisted in relieving symptoms, improving the digestion, and the administration of as much food as the patient could take in the natural way. Artificial feeding had not been resorted to, but the patient was fed six or seven times a day. From two to ten raw eggs, with milk, were given daily to each patient. Alcoholic stimulants were not administered to these patients as a routine treatment, but were used only temporarily for special purposes. He had for several years been systematically cutting down the quantity of alcohol used in chronic cases, and had seen no reason to regret it. His experience had been that alcohol was not used with sufficient discrimination in chronic cases of diseases. Beef, milk, eggs, and other nourishing articles are more expensive than alcohol, but, if they can be consumed in sufficient quantity, they are more useful. In 1883 the amount expended per patient for alcoholic liquors had been two dollars and seventy cents, while in 1886 it had been only thirty-four cents. The patients received no injury, even if they were not benefited, by this reduction. Eight cases of well-marked phthisis were reported in which a decided gain in weight and general improvement resulted from the employment of the plan of treatment above described. About sixty cases had been under treatment.

DISCUSSION.

Dr. E. T. Bruen, of Philadelphia: Of the therapeutic measures under the control of the profession, diet, climate, and suitable hygiene are of principal importance. It is possible by climatic and dietetic treatment to so change the nature of the tissues that they shall not be suitable culture-media for the growth of the bacillus of tuberculosis. He wished, however, to refer more particularly to the use of the Bergeon method by the rectal injection of sulphuretted hydrogen. To antagonize the specific cause of the disease this method has been a failure, so far as his experience went. Since February last he had had under treatment by this method sixty-one cases. Systematic examinations of the sputa were made by Dr. E. O. Shakespeare. There had been no apparent reduction in the number or change in the character of the bacillus. This method should be classed among the available methods for the treatment of this disease. The good effects he had observed were reduction of temperature, reduction of expectoration, very often a complete suppression of bronchial catarrh, and relief of cough. This leads to improved digestion, and enables the dietetic treatment to be carried out with great thoroughness. Forty-four of these cases showed improvement to a certain extent, the average gain in flesh being about five pounds. In one-half of the cases the temperature has been brought to the normal, while in the remainder, although the temperature has not been brought to normal, it has been reduced two or three degrees. In fifteen cases the results have been negative, but in no case did any harm follow the use of this plan of treatment. The improvement has been most marked where there is a considerable catarrhal element. Those cases in which there has been more or less thickening of the lung,

with the general symptoms well marked, wasting, loss of flesh and weight, without much rise of temperature, he found not specially benefited by the injection of gas. In a post-mortem in one case which had been subjected to this treatment, although the cavities in the lungs were unusually clean, he did not observe any evidences of cicatrization. He had not found strong solutions at all satisfactory. The best results have been obtained from a solution of five grains of sulphide of sodium with five grains of chloride of sodium in one and a half pints of water. He did not consider it desirable to administer more than a gallon and a half of gas at one time, and insisted that the injection be made slowly, and that one-half to three-quarters of an hour should be occupied. He had not derived as much satisfaction in the treatment of the various forms of phthisis to which he had referred from any other method as he had from the injection of sulphuretted hydrogen. He always tested the breath for the presence of sulphuretted hydrogen, and had negative results in at least eight out of every ten cases.

Dr. S. S. Cohen, of Philadelphia: The experience of Dr. J. Solis Cohen and myself differs in some respects from that of Dr. Bruen. We have obtained the most decided benefit from strongly-impregnated waters. The best results were obtained in those cases in which the patient had a decided taste of sulphuretted hydrogen, which continued for two or three hours after injection. The best effect has been obtained in those cases in which suppuration is about beginning. Bergeon states that the treatment is directed especially to the suppurative process. In employing this measure, great attention must be paid to detail. In about fifty per cent. of the cases the condition has been greatly ameliorated; in another twenty-five per cent. there has been slighter amelioration; while in the remaining twenty-five per cent. there was more or less benefit to certain symptoms. He had seen no case in which no results were obtained.

Dr. James T. Whittaker, of Cincinnati, has for a month used sulphuretted hydrogen by inhalation, having previously employed it for a month by injection. He began the use of inhalation carefully, and, finding it well borne, had pursued the method more boldly. He now puts the patient in the cabinet and allows him to have all the gas he will take. It has produced no unpleasant results in any case. The effects obtained have been about the same as those resulting from injection. In about one-third of the cases there were no results. After searching the literature for records of bad results following the use of sulphuretted hydrogen, he had found only two in which a fatal result followed. It has been asserted that the good effect is due to the carbonic acid; but he was entirely incredulous of the effect of this agent.

Dr. Roland G. Curtin, of Philadelphia: It has been recommended by Dr. H. C. Wood that the sulphuretted hydrogen be taken by the stomach, using a saturated solution through which carbonic acid has been passed. He had tried this in four or five cases, and has had the same effects as from injection.

Dr. J. H. Musser, of Philadelphia, had used the gaseous injections to a certain extent, but his success had not been as marked as some others'. His best results had been in two cases. One was a case of incipient phthisis, in which the patient gained thirteen and a half pounds in four weeks. The second case has gained eight pounds in four weeks, and has much improved in general condition. He attributed his want of good results in part to the want of enthusiasm on the part of those whose duty it is to carry out the details of the treatment.

Dr. F. C. Shattuck said that he had used the sulphuretted hydrogen gas, and in several patients it produced collapse in varying degrees, with weak pulse, nausea, vomiting, and headache. In several other cases, although the treatment was well tolerated, it produced no good effect. In one case of asthma with chronic bronchitis and emphysema, thirty-four injections of the gas were given. While the treatment did not disturb the patient, it did no good. With the use of the gas was combined the administration of iodide of potassium and other remedies, and the patient recovered in about the same time as on a previous occasion when the latter remedies were given and no gas used.

THE ASSOCIATION OF AMERICAN PHYSICIANS.

(Continued from page 683.)

DISCUSSION ON HEART-MURMURS.

DR. A. L. LOOMIS, New York, said that murmurs within the heart-cavities are due to many different causes. Many are obstructive, while others are due to the impinging of currents of blood upon each other in the heart. They are also due to the force with which the blood-current is carried from the heart into the vessels. They are also due to, or greatly intensified by, the condition of the blood. Occasionally they may be due to irregular action of the heart produced by nervous condition. The obstructive mitral murmurs referred to are of frequent occurrence in connection with aortic disease where there is dilatation and feebleness of heart-power, but on autopsy he had always found such changes in the mitral valves as seemed to account satisfactorily for the murmurs heard.

Murmurs may be readily produced during respiration, but where these murmurs have been persistent he had always found attendant conditions of anæmia and failure of the

right heart. It seems that the explanation is either a hæmic condition or failure of heart-power. As we study the cases more, we shall find that they are due not so much to changes in the valvular orifice as in the heart-cavity and in the heart-walls. Murmurs have very little pathological significance unless there are other changes associated with them. The worst cases of heart-disease have often the simplest and least distinct heart-murmurs.

Dr. E. T. Bruen, of Philadelphia, mentioned a case of anæmia in which the blood-corpuscles were reduced from the normal to one million eight hundred thousand, with a great reduction in the hæmoglobin. There was also great relaxation of the vascular system; so much so that when the arm hung down there was a venous pulse at the back of the wrist. This was attributed to relaxation of the capillary vessels to such an extent as to permit the systolic impulse of the left ventricle to force the blood through the capillaries into the veins. There was no venous pulse in the neck. In this case there were murmurs at each of the valves of the heart. As the anæmia improved and the crasis of the blood was restored, the venous pulse disappeared and the murmurs gradually lessened, and the man has now no murmur whatever. This case is corroborative of the view of the author that in anæmia the murmurs are due to some functional disturbance of the valves.

Dr. F. P. Kinnicutt, of New York, said that it had been claimed by certain observers that pulmonary systolic murmurs are transmitted from the mitral valve into the auricular appendage. The condition required that this may occur is said to be dilatation of the appendage, causing it to approach the chest-wall. In some anatomical examinations he had made a few years ago it was found that in the normal condition the auricular appendage was concealed beneath the pulmonary artery, and when fully dilated its tip only could be seen beyond the edge of the artery. It was even then one and a half inches from the internal surface of the chest.

Dr. F. C. Shattuck, of Boston: When auscultation was first introduced all cardiac murmurs were considered of bad omen. It was then discovered that many systolic murmurs were practically of no importance. We are now finding out that all diastolic murmurs are not of evil import, and that they may be transitory and functional. A murmur by itself is next to nothing; there must be something besides the murmur to make it of much importance. The author has stated that in anæmia there is a reduction in the quantity of the blood. Is not the reduction really more in the quality,—a corpuscular reduction and a reduction in the capacity of the corpuscles for carrying hæmoglobin?

Dr. Samuel C. Chew, of Baltimore, with reference to the diagnosis between aortic regurgitant and mitral direct murmurs, said that the diagnosis can usually be made by attention to the following points. An aortic diastolic murmur, although it may be intense at the apex, becomes manifestly louder as we reach the right side of the sternum in the second intercostal space. It will there occupy the whole diastole. If the murmur is mitral in origin it generally will be presystolic, and will be also heard in the scapular region. The aortic murmur is not apt to be heard in the latter situation.

Dr. Beverly Robinson, of New York, in acute strain of the heart not necessarily brought about by great muscular exertion, had occasionally observed murmurs which unquestionably had nothing to do with organic changes in the heart, and cannot be explained as due to any special modification in the blood. The murmurs seemed to be due to more or less acute dilatation or obstruction of the mitral orifice. These murmurs he believes have considerable prognostic importance; for, if they do not receive careful attention and proper treatment, the condition may progressively develop until a permanent lesion is occasioned.

Dr. Israel T. Dana, of Portland, mentioned the cases of two sisters, one 40 years of age and the other 33, whose mother died with organic heart-disease. Both of these sisters have had a mitral regurgitant murmur. In the older sister the murmur, after remaining for five or six years, disappeared. It remained absent for one or two years, and then returned, and has continued for the past two or three years. In the second case the murmur, after having been present for five or six years, disappeared, and has since remained absent. He asked if it were possible that a murmur connected with organic heart-disease should disappear with improvement of the health and reappear when the health again fails.

The next paper was by Dr. Hosmer A. Johnson, of Chicago, on

PNEUMATIC DIFFERENTIATION,

and was read by the Secretary. The author had compared the results obtained by the cabinet with those obtained by the Waldenburg apparatus, and he held that the former accomplished no more than the latter. The pneumatic cabinet he considered cumbersome and expensive, with nothing specially to commend it in the treatment of pulmonary diseases.

The last paper of the morning session was entitled

METHODS OF LITERARY RESEARCH. BY DR. JOHN S. BILLINGS, U.S.A.

The author referred to the best way of using libraries with especial reference to medical literary work. He also spoke of the great importance of carefully-prepared catalogues

of books, and especially of the work at the library of the Surgeon-General's Office, which deserves to be better appreciated by the profession.

Afternoon Session.

THE ANTIPYRETIC TREATMENT OF FEVER. BY H. C. WOOD, M.D., OF PHILADELPHIA.

The author, in order to make the matter as brief as was possible, had prepared certain propositions or conclusions, which he would read and then give what he thought to be the proof of their correctness. The first proposition was, "Fever is a disturbance of calorification in which, through the influence of the nervous system, heat-dissipation and heat-production are both affected. If there be a fever which is produced by the direct action of a poison independently of the nervous system, we have at present no proof of its existence."

If an animal's temperature rises, there must be a certain number of heat-units used in producing that rise. If the temperature falls, there must be a corresponding lessened production of heat. In his experiments the agent used to produce the fever has been the pyrogenic principle found in ordinary commercial pepsin. After the substance has been introduced, the animal is put into a calorimeter. The animals used in the experiments have been dogs. In the normal animal, heat-production and heat-dissipation are correlated functions. When the poison is injected, it is found that heat-dissipation increases at the time that heat-production is diminishing, so that the fall of temperature was in part the result of heat-dissipation and in part the result of diminished heat-production. It is impossible that there should be this wide disturbance of these two functions simultaneously, unless the poison which produces the fever acted upon some one central organ, and that must be the nervous system. McAllister, of London, while believing that fever is often produced through the nervous system, thinks that at times it may be produced by widespread tissue-change caused directly by the poison, his reasoning being that in the advanced stage of fever the temperature is higher than at the beginning. He says that the time when the poison is at its maximum does not correspond to the time when the fever is at its maximum. The objection to this argument is that we do not know that the poison of the disease is the direct cause of the fever. The poison which causes the disease in scarlet fever, etc., is probably not the poison which causes the fever. The latter is probably generated in the system.

Second, "Heat-production is regulated by a nervous apparatus, our knowledge of which is still imperfect. There is certainly an inhibitory centre which depresses or controls the production of heat. It probably does this by acting upon the trophic cells of the gray matter of the spinal cord. It is possible also that there is a centre which, when excited, increases tissue-change, but its existence has not yet been proven." The speaker then gave a résumé of the experiments which he had performed which in his opinion proved the truth of the above proposition.

Third, "Heat-dissipation is regulated through the vaso-motor system, so that vaso-motor paralysis is followed by an enormous loss of animal heat, and, under unfavorable circumstances, even by death from cold." If section of the cord is made in such a way as to get vaso-motor paralysis without destruction of the respiratory centres, the heat-dissipation rises enormously, and if the animal is kept in a temperature of 50° or 60°, it dies in a few hours of progressive loss of heat, but if kept in a warm chamber it lives for days. The cause of the rapid heat-dissipation is the dilating of the blood-vessels of the surface of the body.

If these remarks are applied to a study of antipyretics, it is seen that drugs may lower bodily temperature in health or in fever by increasing heat-dissipation. In this way all agencies act which cause vaso-motor paralysis. Antipyretics acting in this way may be called false antipyretics. Aconite, veratrum viride, and drugs of that class belong to the false antipyretics. Then it is conceivable that there may be drugs which act on heat-production through the inhibitory nerve apparatus of which mention has been made. Such drugs may for convenience be called true antipyretics. Whether or not there are any true antipyretics has, until recently, been a question which we have been unable to answer. With regard to antipyrine, certain experiments made in the University of Pennsylvania seem to give positive results. Care must be exercised in these experiments not to confound a normal defervescence with the action of the drug administered. In the dog the use of antipyrine diminishes both heat-production and heat-dissipation, the former being diminished more than the latter. It is probable that heat-production is primarily affected. The question arises whether this result is due to an effect on the circulation. He had found that antipyrine had no effect upon the circulation. The blood-pressure was uninfluenced by its administration. He therefore concluded that the action of antipyrine upon the bodily heat was entirely independent of any action upon the circulation, and the probabilities are of course that it acts through the nervous system. Beyond this our present knowledge does not extend.

Francis Minot, M.D., of Boston, read the next paper, on

THE TREATMENT OF TYPHOID FEVER BY ANTIPYRINE AND THALLINE,

based on the observation of twenty-four cases treated in the Massachusetts General Hospital, the object of the study being to

ascertain the proper dose of the drugs, their general and specific effects upon the patients, the results from their continued use as compared with those from their occasional employment, any unfavorable results, and the general effect of antipyrine and thalline upon the course of the disease.

The following conclusions were reached: 1. Both antipyrine and thalline have a remarkable power of reducing the temperature in typhoid fever. 2. In no case was the use of these refrigerants apparently followed by any unfavorable effect upon the course of the disease. 3. The general condition of the patient was more comfortable after taking antipyrine and thalline, which were often followed by sleep. 4. The refrigerant medication by antipyrine and thalline appears to have no specific or decided effect upon the course or issue of typhoid fever. It often contributes much to the patient's comfort, perhaps indirectly promotes his safety. 5. The effect of antipyrine and thalline in promptly lowering the temperature shows that the danger in typhoid fever does not consist in high temperature alone, and that the latter is rather an index of the violence of the abnormal condition which we call fever, though perhaps adding somewhat to the danger. 6. By the internal use of antipyrine and thalline all the effects which are claimed for the treatment of typhoid fever by the cold bath are readily obtained without the trouble and inconvenience of the latter method, and without exposing the patient to the dangers of exhaustion and shock consequent on the fatigue of removal from bed. 7. These remedies may be given without danger to the youngest patients in suitable doses, and, indeed, their beneficial effects are more decided and unfavorable consequences are less observable than with adults.

(To be continued.)

NEW YORK ACADEMY OF MEDICINE.

A STATED meeting of the Academy was held May 5, 1887, the President, A. JACOBI, M.D., in the chair.

DONATIONS TO THE ACADEMY.

Dr. FRED. A. CASTLE, Treasurer of the Board of Trustees, acknowledged the receipt of seventy thousand dollars from Mrs. Hosack, as a building fund, given in honor of her deceased husband. Mrs. Hosack also gave ten thousand dollars, or as much thereof as might be necessary, to acquire a bed in Roosevelt Hospital to be known as the Hosack Bed, the occupant of which is to be a deserving physician; its control to be under the officers of the Academy.

It was announced also that five thousand dollars had been received for a library fund, to be known as the Philippine Meyer and Ernst Jacoby Library Fund.

A memoir of Dr. H. P. FARNHAM was read by Dr. P. A. MORROW.

ON THE ULTIMATE RESULTS OF THE MECHANICAL TREATMENT OF HIP-JOINT DISEASE—AN ANALYSIS OF FIFTY-ONE CASES OCCURRING IN THE NEW YORK ORTHOPÆDIC DISPENSARY AND HOSPITAL.

The paper was by Dr. NEWTON M. SHAFFER, of New York, and Dr. ROBERT W. LOVETT, of Boston. Dr. Shaffer read the paper.

The more conservative methods of treatment had not received the attention they should. The object of the paper was to show the results of such treatment. The cases were drawn from the dispensary class only. Private cases, those from the hospital, and those upon which exsection had been performed, were eliminated from the list. The object was to show the ultimate result of strictly-speaking mechanical treatment of hip-joint disease in dispensary patients. No case was considered which had not been under the care of the institution from the time of entry to the final discharge; no case was considered which had not been discharged cured at least four years prior to the investigation; no case was considered unless it showed unmistakable signs of disease at the time of the first examination; none was considered which had not been at least two years under treatment; none was considered which had not been seen or examined after the investigation was commenced; all cases coming under these exclusive conditions were classified and reported. These conditions, the writers thought, must satisfy even the most exacting critic.

From 1877 to 1882, seven hundred and seventy-eight patients with hip-joint disease were treated in the dispensary. During these five years one hundred and sixty-eight patients, or 21.59 per cent., were discharged cured; fifty died with disease dependent upon the hip-joint condition. It might be stated that many, if not all, of the cases were experimentally discharged as cured before they were entered as actually cured.

The general plan of treatment was as follows: the long Taylor traction splint was applied soon after the first examination; unless the recumbent position was necessary, or the disease was so acute as to demand rest, the patient was allowed almost unlimited exercise in the open air. He was to call at the dispensary every week or two. The aim of treatment was to overcome any mechanical disadvantage acquired before the treatment was commenced; to protect the diseased joint from traumatism; to permit the patient to have almost unrestricted out-of-door exercise; to maintain the best position of the limb, or reduce deformity to a minimum if anchylosis occurred.

In no case was any operative measure employed, except occasionally to open an ab-

scess, but abscesses were not interfered with, as a rule, unless there were positive indications for the knife. As a matter of experience, abscesses connected with hip-joint disease did no better under antiseptic conditions than those under simple incision, and neither did better than when opening took place spontaneously.

The long splint without any joint at the knee was used from the beginning to the end of the treatment. In private practice, where the patients could afford to pay for it, a splint with joints was employed.

Of the entire number of cases treated at the dispensary from 1875 to 1882, only fifty-one coming under the restrictions of this paper could be traced. Of these fifty-one cases four had died: two of meningitis, two of pneumonia. Six of the patients had had a relapse. They had been under treatment two and one-half, four, four, four, five, and seven years respectively; two remained well three years, two four years, and one five years before a relapse occurred. In one case the relapse was due to a fall from a cart. Of the cases which had relapsed one had afterwards entered a hospital for excision at the hip, two were still wearing the traction splint and were nearly cured a second time, one was on crutches slowly improving, the remaining two had been cured a second time by the traction apparatus. The remaining forty-one cases had been examined excepting two, which were well. Of the thirty-nine cases examined four had been under treatment two years, four for two and a half years, nine for three years, six for three and a half years, eight for four years, two for four and a half years, two for five years, one for six years, one for six and a half years, one for seven years, and two for eight years. Of the thirty-nine cases, the disease had lasted before they came under observation for a less time than six months in eight cases, between six months and a year in eighteen cases, between one and two years in three cases, between two and three years in five cases, six years in one case, seven years in one case, nine years in one case, and for an indefinite time in two cases.

Of the thirty-nine cases, twenty-seven had one or more abscesses at some stage of the disease; twelve had none, but the latter were by no means the least marked cases, or those in which the best results were obtained. There was shortening of the limb as much as one and a half to two inches in all of the cases excepting two; in these there was no shortening. The amount of shortening did not seem to depend upon the presence or absence of abscess. In one case there was six inches shortening. The two cases cured without any shortening were cured before the tenth year of age. Eighteen cases cured before the tenth year represented an aggregate of twenty-five inches shortening, while nineteen cases cured after the tenth year represented in the aggregate thirty-eight inches shortening. The shortening was principally in the femur; the tibia shared it to a certain extent. The difference between the length of the two limbs almost invariably increased slowly after the disease had been cured, but the shortening did not increase indefinitely. In the cases in which eight or ten years had elapsed between the two measurements, no greater shortening was present at the last measurement than existed two or three years after the cure.

In no case was the difference in the circumference of the two thighs less than one inch. It would appear there might be a maximum of muscular atrophy with a minimum of bone-shortening, and *vice versa*. It seemed the nutrition of the muscles, bones, etc., in hip-joint disease received a shock from which it never afterwards recovered.

In nineteen cases there was practically anchylosis of the joint: in twelve of these there had been abscess, in four no abscess; with slight motion there were four cases with abscess, two without abscess; from ten to forty-five degrees of motion, five cases with abscess, two without abscess; with ninety degrees of motion, three cases with abscess, no case without abscess; with perfectly free motion, two cases with abscess, one without any abscess. Examination proved that motion became less as time went by. In two cases in which there had been ninety degrees of motion several years ago there was at the last examination only thirty degrees.

In fifteen of the cases in which there was little or no motion at the articulation there was no flexion of the thigh; the limp in these cases was trivial. In the cases in which the angle between the flexed thigh and the body was one hundred and twenty to one hundred and thirty-five degrees the impediment to motion was not serious, except in one case, in which there was caries of the lumbar spine. Permanent adduction of the thigh was a much more serious matter. Adduction was likely to occur after removal of the splint and increase up to a certain point. Adduction was present in thirty-three cases, but in only one was it very troublesome.

In only one case of forty examined was there anything which approached at all to true lateral curvature of the spine.

DISCUSSION.

Dr. LOVETT, of Boston, made some remarks, and said he considered adduction the most important factor in cured cases of hip-joint disease. There might be a good deal of bone-shortening with little inconvenience in walking, but slight shortening from adduction caused the gait to become ungainly.

Dr. RIDLON thought the paper showed that cases of hip-joint disease could be treated successfully at a properly-equipped dispen-

sary. He thought some cases were based on a tubercular, others on a syphilitic diathesis; some had a traumatic origin. He would also employ therapeutic measures.

Dr. KETCH said the advantage of the mechanical treatment was not alone in obtaining good final results, but in relieving the patient of pain and enabling him to go about during the treatment.

Dr. LEWIS A. SAYRE thought that, whatever the predisposing cause, the cases could be traced to some traumatism as an exciting cause. He thought the results of treatment regarding motion were much better in his private practice than in the cases seen in dispensary practice by Dr. Shaffer. He was a strong advocate of mechanical treatment, but there were conditions in which excision of the dead bone should be performed, otherwise the patient would die from amyloid degeneration of internal organs.

Dr. V. P. GIBNEY had become a convert to the mechanical treatment of hip-joint disease. The results in cured cases seemed in two respects to be different from what orthopædic surgeons usually led their patients to hope for. It was shown by these statistics that the shortening increased for a time, instead of diminishing, after the cure; further, that the diminished size of the affected limb was not overcome.

Dr. JUDSON thought a large shoe on the instrument or affected limb, instead of the small one usually worn, might tend to make adduction in walking more difficult, by preventing the patient from taking his weight off that limb as quickly as he was inclined to do.

Dr. TAYLOR, Dr. L. H. SAYRE, and Dr. SHAFFER continued the discussion.

NEW YORK PATHOLOGICAL SOCIETY.

A STATED meeting was held June 8, 1887, the President, T. MITCHELL PRUDDEN, M.D., in the chair.

Dr. PUTNAM JACOBI presented for a candidate a specimen of

ACUTE ATROPHY OF THE STOMACH, WITH FATTY DEGENERATION OF THE HEART.

Dr. DUDLEY presented

THE UTERINE APPENDAGES

of a girl aged 22. At the age of six years the patient had had smallpox, from which she made a good recovery. From six to twelve years of age she had the exanthemata and diphtheria. At twelve she would occasionally faint, and at times complained of headache. At maturity her headache grew steadily worse, and was most severe at the menstrual period. She was then put under the care of a physician, who made the diagnosis of hysteria. Another physician treated her for rheumatism, a third for chronic meningitis; a fourth applied electricity, which made her condition worse; a fifth treated her for rheumatism of the brain. Finally she came under the care of Dr. Hammond, who treated her for brain-congestion, together with other symptoms. She was always of a lively disposition when not in pain. She had never had a true spasm. Dr. Hammond placed her in the care of Dr. Dudley, who found that she was well nourished, that her menses were regular. She suffered no pain except in the head until lately, when she had pain in the side one week before and one week after menstruation. She had taken large quantities of medicine, and had been treated by almost every means for the relief of her nervous condition. She had been a masturbator for years, but said she had given up the habit some months past. The vulva was so hyperæsthetic that a physical examination was very difficult. The meatus was surrounded by a large caruncle. From a superficial examination he found the uterus retroverted, and the ovaries and tubes correspondingly low. At a second examination without ether, he was able only to replace the uterus. Saturday last he examined her under ether. The left ovary seemed to be small; the right ovary seemed to be somewhat enlarged and very sensitive. After consultation, and having obtained the previous consent of the patient, and of her brother, who was a physician, it was decided to make an exploratory operation. The right ovary was found somewhat enlarged, and contained a cyst about the size of an English walnut; the tube was tortuous, and the fimbriated extremity was bound down below the ovary; the ovary and tube were removed. The left ovary was found to be small, and contained a small cyst; the tube was tortuous and bound down to the pelvic floor, and quite close to the intestine; beneath it was a large varix. This ovary and tube, together with the varix, were removed. The patient had since done well.

A point of special interest in the case related to the varicose veins. This was the third case of the kind which he had operated upon during the past year. In all there had been failure to relieve the reflex symptoms by various ordinary measures, such as repairing a lacerated cervix, curetting for a fungous condition of the uterus, the administration of drugs, etc. In the first two cases the pain in the side and other reflex symptoms disappeared after removal of the ovaries and varix. The ovaries were not much enlarged. In the third case the operation had very recently been performed. Dr. Dudley thought that inasmuch as a varicocele in the male might give rise to almost all kinds of reflex symptoms, so also might an analogous condition exist in the female.

Dr. PUTNAM JACOBI thought it would be interesting to know whether or not the small ovary was the seat of interstitial ovaritis. Two years ago she reported three cases in

which the ovaries did not present any very marked lesion when examined macroscopically, but when examined microscopically there was found degeneration of the arteries and the signs of interstitial ovaritis, and she thought this was much more the cause of the severe nervous symptoms which had existed than was any slight cystic degeneration. In fact, a cyst of considerable size might exist and cause no suffering or tenderness when pressure was made over the abdomen. She referred to the case of a young lady, who, before coming East, had undergone at least one year's continuous treatment in a Western State for symptoms related presumably to an existing enlargement and prolapsus of both ovaries. The treatment by galvanism was continued, and an attempt was made to replace the ovaries, and a boro-glyceride cotton tampon was introduced into the vagina. At first this local treatment seemed to be beneficial, but the relief proved to be only temporary, and the tampon after a time seemed to cause irritation. Local treatment was then discontinued two or three months, during which time the patient received simple massage, to some extent electrical massage, the cold pack with rubbing, and general treatment. Under this plan the pain in the back and the nervous symptoms generally had entirely disappeared, also the tenderness on pressure over the ovaries, although the organs remained prolapsed and enlarged. Dr. Jacobi had seen at least two or three cases in which the enlarged and prolapsed condition of the ovaries had continued after relief of all the apparently associated symptoms.

Dr. DUDLEY requested that his specimen be submitted to the Committee on Microscopy. The request was granted. Referring to the remarks of Dr. Putnam Jacobi, he expressed the belief that cotton tampons with boro-glyceride produced their beneficial effect by causing contraction of the vessels and reducing uterine congestion. He did not think that in his case there had been acute ovaritis; the patient had not complained of pain in the region of the ovary until very recently. As to the relief of symptoms by cotton tampons containing glycerin, he had two cases of prolapsus of both ovaries and tubes in which such treatment would cause almost entire disappearance of the symptoms for a month or two, but they would return with each new exposure to cold, over-exertion, etc.

Dr. PUTNAM JACOBI thought that in the case related by her the uterus was perfectly healthy, and the tampons had produced only slight relief, whereas the general treatment had caused entire cessation of the subjective symptoms.

The PRESIDENT said it was so seldom one found a normal ovary that it was difficult to obtain a sufficient number for demonstration before students. Interstitial ovaritis was very common, even in cases in which there had been no history of symptoms associated with it during life.

Dr. W. P. NORTHRUP asked Dr. Dudley whether he had noticed in his cases any of the changes in the features alleged to take place after removal of the ovaries.

Dr. DUDLEY replied that in none had he noticed any change, excepting that usually there was an increase in flesh, and some patients complained of flushes in the head after removal of the ovaries.

EPILEPSY—BONY EXCRESCENCES ON THE INNER SURFACE OF THE CRANIUM.

Dr. THATCHER presented the skull of a colored woman, aged about 35 years, who had complained of severe headaches for three years, which she thought were due to menstrual troubles, of which she had some. There were chronic changes in the kidneys, but no diagnosis of kidney-disease had been made by the physician in charge. The urine had, according to the report, been of fairly high specific gravity and contained no albumen. There was no history of venereal disease. During the past three months the patient had had occasional attacks of vertigo, with loss of consciousness and falling to the ground. The attacks became more and more frequent towards the end of life. She gradually weakened and died. The diagnosis made was epilepsy. There were found, at autopsy, bony excrescences on the inner surface of the frontal bone, and some calcified masses in the dura mater. The dura was closely adherent to the skull.

REMOVAL OF THE RIGHT HALF OF THE LOWER JAW BY SLOW ENUCLEATION.

Dr. JOSEPH W. HOWE sent a man who in October last received a severe blow on the under surface of the chin, exposing the bone. The wound was sewed up at St. Luke's Hospital, but failed to unite. The jaw afterward became much swollen and painful, and the patient sought admission to St. Francis's. Dr. Howe made an examination early in November, and found a swelling extending from the symphysis to the posterior part of the ramus of the jaw on the right side. A small sinus led to the dead bone. The teeth were loosened, the alveolar processes were stripped bare, were rough, and bathed in pus. The periosteum was separated along the upper line of the jaw back to the ramus, and in some places was completely destroyed. The lower teeth were removed from the jaw the following day, and a portion of the periosteum separated. This process of separating the periosteum was continued for several weeks, the parts were thoroughly cleansed, and the general health was looked after. With the stripping of the bone the periosteum gradually thickened so as to increase the swelling on the affected side. Finally, he was

able to pull out the diseased jaw, leaving behind a good basis for a new jaw in the ossifying periosteum. The patient, when presented, had a new jaw, which had grown from the periosteum of the old jaw.

A CASE OF INTUSSUSCEPTION.

Dr. W. P. NORTHRUP presented the specimen, removed from a boy aged 5 months, who was cared for during his illness "between" two or three physicians, which would account for the meagre history and lack of diagnosis. The child was strong, and had had no previous disease. Forty-eight hours before death, the record stated, he had severe diarrhœa, with vomiting. During the last twelve hours the vomiting increased in severity, and the diarrhœal discharges became bloody mucus. The patient cried shrilly, and had "inward convulsions." Death took place forty-eight hours after the commencement of the symptoms. At the autopsy the abdomen was tensely distended. The distention was found to be wholly of the small intestines. The stomach was empty, the colon and rectum collapsed. The small intestines were normal, except that there was a little swelling of Peyer's patches. The colon and rectum were smeared with blood-stained mucus. The only lesion found was a tumor four inches long, an inch and a quarter thick, round, firm, the color bluish, which was found to be an invagination of the cæcum into the transverse colon. The latter was in normal condition, the former deeply congested. The gut was believed to be not gangrenous.

TREATMENT OF ALOPECIA AREATA. — Schachmann (*Annales de Derm. et de Syph.*, vol. viii. No. 1) has followed successfully M. Vidal's treatment of alopecia areata by blisters. The whole surface of the area is blistered, the blistered surface being treated in the ordinary way. Generally within three days it is possible to apply another blister. Three, four, up to six or even ten blisters are used successively; and, in addition, the rest of the head is rubbed night and morning with a lotion consisting of water one hundred, turpentine twenty, ammonia five. When the affected surface is very large, or when the whole head is affected, the part to be treated is divided into fields, and the fields are treated successively. The circumference of the area is shaved to the extent of about a centimetre. Twenty-nine cases are related in which this method was employed. Ten of these were also treated by stimulating applications, such as pyroligneous acid and croton oil, which gave no good result in spite of long treatment. The duration of the malady never exceeded three months from the time the blisters were begun. In a number of cases it did not reach two months, and in others a cure took place much sooner. Sometimes the hair began to grow after three or four blisters.—*London Med. Record.*

OFFICIAL LIST

OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U.S. ARMY FROM JULY 17, 1887, TO JULY 30, 1887.

COLONEL D. L. MAGRUDER, SURGEON.—Granted leave of absence for one month, to take effect on or about August 10, 1887. S. O. 170, A. G. O., July 25, 1887.

Paragraph 13, S. O. 167, A. G. O., July 21, 1887, assigns LIEUTENANT-COLONEL A. HEGAR, SURGEON, to duty as member of Army Retiring Board convened at Governor's Island, New York Harbor, New York, *vice* COLONEL CHARLES SUTHERLAND, SURGEON, hereby relieved.

MAJOR D. G. CALDWELL, SURGEON.—Order relieving him from duty at Fort D. A. Russell, Wyoming, and assigning him to duty at Fort Assiniboine, Montana, is revoked. S. O. 168, A. G. O., July 22, 1887.

MAJOR P. J. A. CLEARY, SURGEON.—Ordered to Fort Assiniboine, Montana, instead of Fort D. A. Russell, Wyoming. S. O. 168, A. G. O., July 22, 1887.

MAJOR ELY MCCLELLAN, SURGEON.—Detailed as member of a board of survey to meet at the medical purveying depot, St. Louis, Missouri, on August 1, 1887. S. O. 173, A. G. O., July 28, 1887.

CAPTAIN S. G. COWDERY, ASSISTANT-SURGEON.—Granted one month's leave of absence, to take effect on or about July 24. S. O. 79, Department of Texas, July 13, 1887.

By paragraph 43, S. O. 162, A. G. O., July 15, so much of paragraph 1, S. O. 156, c. s., A. G. O., as directs CAPTAIN JOHN DE B. W. GARDINER, ASSISTANT-SURGEON, to report for duty at Fort Washakie, Wyoming, is revoked.

By paragraph 42, S. O. 162, A. G. O., July 15, so much of paragraph 1, S. O. 156, c. s., A. G. O., as relieves CAPTAIN GEORGE H. TORNEY, ASSISTANT-SURGEON, from duty at Fort Monroe, Virginia, is revoked.

CAPTAIN R. BARNETT, ASSISTANT-SURGEON. — Sick-leave still further extended six months, on account of sickness. S. O. 162, A. G. O., July 15, 1887.

CAPTAIN H. G. BURTON, ASSISTANT-SURGEON.—Sick-leave of absence extended three months. S. O. 171, A. G. O., July 26, 1887.

CAPTAIN E. F. GARDNER, ASSISTANT-SURGEON.—Ordered for duty at Fort Reno, Indian Territory. S. O. 170, A. G. O., July 25, 1887.

CAPTAIN A. W. TAYLOR, ASSISTANT-SURGEON.—Now at Fort Laramie, Wyoming, is ordered for temporary duty at Fort Robinson, Nebraska. S. O. 162, A. G. O., July 15, 1887.

FIRST-LIEUTENANT C. S. BLACK, ASSISTANT-SURGEON.—Ordered for duty as post-surgeon, Fort Bliss, Texas, during the absence on leave of Captain S. G. Cowdery, Assistant-Surgeon. S. O. 79, Department of Texas, July 13, 1887.

FIRST-LIEUTENANT W. D. MCCAW, ASSISTANT-SURGEON.—Ordered for temporary duty at Fort Riley, Kansas. S. O. 78, Department of Missouri, July 25, 1887.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U.S. MARINE HOSPITAL SERVICE FOR THE WEEK ENDING JULY 23, 1887.

FESSENDEN, C. S. D., SURGEON.—Granted leave of absence for thirty days, on account of sickness, July 18, 1887.

MEAD, F. W., PASSED ASSISTANT-SURGEON. — Granted leave of absence for thirty days, July 19, 1887.

YEMANS, H. W., PASSED ASSISTANT-SURGEON.—Granted leave of absence for thirty days, July 23, 1887.

BROOKS, S. D., PASSED ASSISTANT-SURGEON.—Promoted and appointed Passed Assistant-Surgeon from July 1, 1887, July 21, 1887.

WHITE, J. H., ASSISTANT-SURGEON.—To proceed to Washington, D. C., as escort to an insane seaman, July 18, 1887; ordered to examination for promotion, July 23, 1887.

WATKINS, R. B., ASSISTANT-SURGEON.—Leave extended fourteen days, on account of sickness, July 20, 1887.

MAGRUDER, G. M., ASSISTANT-SURGEON.—To proceed to Galveston, Texas, for temporary duty, July 21, 1887.

PHILADELPHIA, AUGUST 20, 1887.

ORIGINAL LECTURES.

CLINICAL LECTURE ON THE TREATMENT OF SUMMER COMPLAINT.

Delivered at the Medico-Chirurgical Hospital of Philadelphia

BY WILLIAM F. WAUGH, A.M., M.D.,

Professor of Practice of Medicine, and of Clinical Medicine, in the Medico-Chirurgical College, etc.

THE treatment of summer complaint, or cholera infantum so called, has not been hitherto very satisfactory by the methods usually employed. Mild cases recover under the most varied methods of treatment, while severe cases in unfavorable weather usually die. In all forms of the disease it must be admitted that well-directed hygienic management of the individual and his surroundings is of the first importance. As organic substances decompose rapidly in hot weather, the utmost care should be taken to remove all animal and vegetable impurities from the premises and immediate neighborhood. In one of my cases, where the family resided near the Delaware River, every rise of the tide filled the house with the effluvia from the cesspool, which communicated directly with the river by means of an untrapped drain. This child improved every day while absent from home at the Sanitarium, but became worse when brought back to the house for the night. Another child, it was noticed, was worse whenever it was taken into the kitchen, where one wall was constantly damp from the leakage from a neighboring vault.

The custom has heretofore been to rely mainly upon milk as the proper food, if not the only food, for infants. The investigations of Vaughan, resulting in the discovery that the poisonous tyrotoxicon can be generated in milk under certain conditions, have cast a serious doubt upon the innocuity of this food. Apart from this, it would seem *a priori* that a more unsuitable food for infants in hot weather could scarcely be found. Leaving out of consideration the question of the communication of disease from the animal supplying the milk, and the adulteration of it, especially with impure water from barnyard wells, it may be noted that, of all animal products used as food, milk is the most prone to decompose and to absorb poisonous emanations from surrounding sources. Should you place a pan of fresh milk in a refrigerator with a bit of tainted fish, in an hour you would find that the milk will not only have taken up the odor of the fish, but will have acquired its poisonous properties; so that any person drinking the milk will be as likely to have cholera morbus as if he had eaten the spoiled fish. To this proneness to decomposition, if we add the confessed necessity of absolute *surgical* cleanliness in preparing the milk for the child's use, it may well be said that a more dangerous food—for city children, at least, in hot weather—could not readily be devised.

My experience with summer complaint previous to the present summer has not been satisfactory. Several times I thought that I had found a remedy, but subsequent experience did not fulfil my first anticipations.

In summing up the treatment of this disease, Meigs and Pepper give a formula containing "Haller's acid," and state that the authors intend to "give it a trial next summer." That final sentence speaks volumes of the utter failure of the methods used previously, and of the realizing of the necessity for some more efficient agent; and yet of the unwillingness of the physician, when confronted with a desperate case, to trust untried remedies. I have known scores of physicians who, at the close of a disastrous summer, were going to try "Haller's acid" next season; but the first serious case of next summer found them back at their calomel, bismuth, etc.

I have tried Haller's acid, and found it possess no properties superior to the aromatic sulphuric acid.

When the present season opened, I determined to adopt a different system from any I had previously used. First, I excluded milk rigorously from the food of every child who suffered with any form of bowel disorder or "summer complaint." I restricted the diet to the white of egg mixed with three times its bulk of cold water, with stale bread toasted in the oven until a rich dark-brown color throughout, and then rolled into a powder and softened with boiling water. In some cases I gave Lactated Food, and in one Malted Milk, each with good results. I endeav-

ored to obviate the exhaustion due to sweating, by restricting the amount of fluid imbibed, and by giving plenty of salt with the food. To diminish the effects of excessive heat, I ordered a tub of tepid water to be placed in the middle of the room, and the child allowed to get into the water whenever he desired, and remain in it some minutes. In one case the improvement began with the first bath.

The choice of medicinal agents will, of course, depend upon the view taken of the pathology of the disease.

Hayem has recently given the results of some very interesting investigations upon the nature of the green diarrhœa which is so common in the French foundling asylums. He found that this green diarrhœa disappeared most promptly when lactic acid was given in doses of six to nine grains daily; that the disease very uniformly reappeared until the precaution was taken of disinfecting the stools as soon as they were voided, by placing them in a solution of corrosive sublimate (one to one thousand). These measures completely eradicated the disease from the institution, and it did not reappear until a new child entered who brought the affection with it. In every case it was found that strict enforcement of the antiseptic precautions caused the disappearance of the diarrhœa.

A microscopic examination of the green stools revealed the presence of a peculiar microbe, to which Hayem attributes the disease. To this I attach but little importance, as the modern bacteriophile who goes hunting with his little microscope rarely fails to bring home game.

But there are other reasons for considering it probable that the symptoms of summer complaint are really due to the circulation in the blood of a poison generated by micro-organisms in the gastro-intestinal tract.

We have learned to associate the hot head, icy extremities, intense fever, and abdominal pain occurring in puerperal cases to the presence of decomposing substances in the uterus. We know also what prompt relief follows the removal of these noxious matters. Such relief could not be obtained were the symptoms due to the presence of microbes in the blood, and the fact that the relief does occur shows that the generating cause is removed.

So, also, in severe cases of naso-pharyngeal diphtheria, with the frightfully fetid breath we have constitutional symptoms markedly resembling those of puerperal septicæmia. There is the same intense fever, the burning forehead, and icy feet. The relief which follows a thorough cleansing of the throat and the nasal cavities is greater than would be believed possible by those who have never taken the pains to do it. That this relief is not always lasting, as it is in puerperal septicæmia, is due to the fact that in diphtheria there is a true migration of bacteria into the blood, where they multiply undisturbed by our therapeutics.

Now, in severe cases of summer complaint we have a train of symptoms strikingly similar to those of the two diseases just mentioned. We have the intense fever, burning head, hot and tender abdomen, cold extremities, and stools whose fetid odor gives evidence of decomposition.

Few children die of diarrhœa except when chronic enteritis remains after the subsidence of the acute attack. Death is usually due to fever, with symptoms of hydrocephaloid or cerebral paralysis.

Taking this view of the pathology of summer complaint, we have a definite basis for our therapeutics. We need no longer wage a guerilla warfare, a little war of outposts and detachments, but we can bring the matter at once to issue in a pitched battle. We can attack our as yet unknown enemy by throwing germicidal shells into his camp.

As we are ignorant of the peculiarities of this particular germ, we can only ascertain the most suitable germicide by experiment. I concluded to begin the season with the sulpho-carbolate of zinc, and not to lay it aside until I had demonstrated its inefficiency. Thus far the success of the method has been such that no reason for a change exists. Out of nearly thirty cases treated by myself and Dr. Taylor there have been no deaths. These cases covered every grade of the disease, including catarrhal gastro-enteritis, inflammatory entero-colitis, and true cholera infantum. At first the zinc salt was given in doses of $\frac{1}{16}$ grain every two hours, with one to five grains of bismuth. As the remedy was well borne, the dose was increased to one-fourth grain for a child in its second summer. The first and invariable effect has been to stop the vomiting. The stools became less offensive, although

in some cases they continued to be copious and frequent. In these cases we gave enemata of flaxseed tea containing five grains of the sulpho-carbolate and half a drachm of bismuth. This proved effectual in all cases.

Intense fever was met by antipyrine in doses of one to two grains. This drug appears also to have a disinfectant action upon the stools.

When the child has improved somewhat, mutton-broth with rice has been added to the diet; then weak coffee, brandy, meat (to be sucked), especially salt meat, and chicken jelly.

Whether this plan of treatment will withstand the test of subsequent experience remains to be seen.

The sulpho-carbolate of zinc has the advantage over naphthalin and salicylic acid of being more palatable and less irritating to the stomach. Antipyrine has the same advantages over quinine, when an antipyretic is required. That the bismuth had but little action except as a vehicle we proved by occasionally giving it without the zinc salt.

ORIGINAL COMMUNICATIONS.

REVIEW OF PROGRESS IN MEDICAL AND SURGICAL ELECTRICITY.

BY WILLIAM R. D. BLACKWOOD, M.D.

GALVANO-CAUTERY IN UTERINE AFFECTIONS.

A SYNOPSIS of results obtained in diseases of the endometrium and in fibroids was lately given in the *British Medical Journal*, the methods employed being those of Apostoli principally. Dr. Lucien Carlet embodies the result of this plan in a monograph, "Du Traitement électrique des Tumeurs fibreuses de l'Utérus," and Apostoli follows in another, "Sur un nouveau Traitement de la Métrite chronique, et en particulier de l'Endométrite, par la Galvano-caustique chimique intra-utérine." Full histories of several hundred cases are given, and the conclusions drawn may be thus summarized:

1. The method is essentially the application of a constant and continuous current to the uterus.

2. The seat of application is always the whole extent of mucous surface.

3. If the cavity is unattainable, a puncture is made, followed by galvano-caustic action, thus making an artificial channel.

4. The active intra-uterine pole must always be positive in hemorrhagic fibromas or in accompanying obstinate leucorrhœa; negative in dysmenorrhœa.

5. The greatest possible strength must be used up to the limit of toleration,—one hundred to two hundred and fifty milliampères.

6. From five to ten minutes must elapse before effective cauterization is attained.

7. The applications are repeated according to the size and solidity of the tumor or extent of diseased tissue, generally bi-weekly.

8. The presence of active hemorrhage is not a contra-indication for electrolysis.

9. To overcome pain or eschar, the abdominal electrode is of potter's clay applied over a wide surface.

10. The operation is virtually a cauterization with a high degree of electro-chemical action.

11. Proper applications bring about rapid elimination of fibroid tumors; hemorrhages are arrested, and health is assured.

For some years past we have advocated strong currents as perfectly safe in pelvic work, although the profession has tied itself down to a maximum of forty to fifty milliampères. Apostoli goes up to two hundred and fifty milliampères, and we have repeatedly excelled that by one hundred milliampères without injury.

Dr. Woodman Webb reiterates all the above in a published letter, after observing the practice of many operators and comparing results in electrolysis with the usual surgical procedures. Many interesting communications on this subject appear in the *British Medical Journal* for May, June, and July, by eminent authorities.

In some rare cases galvano-cauterization is not immediately applicable. These exceptions are of three kinds: those of extreme temporary excitability (hysterical); those called by Apostoli "*entérite glaireuse*;" and those presenting a subacute form of perimetritis. Such conditions must be overcome by appropriate treatment prior to employing electricity. Occasionally perfect intolerance is observed, according to Webb and others.

This we do not for a moment believe, as the physical operation of electrolysis is available in any case despite any or all nervous accompaniments. Under anæsthesia, any needed electrical procedure is readily carried out, and hysterical complications cannot in any degree influence the result of such treatment. With delicacy of manipulation, knowledge of the physics involved, and definite diagnosis, no danger is possible.*

ELECTROLYSIS IN CYSTIC OVARIAN TUMORS.

Dr. Semeleder has read before the Academy of Medicine of Mexico a memoir reporting the results in forty-five cysts treated by electricity, the outcome of which was so satisfactory as to lead him to endorse strongly the procedure before resorting to the ordinary enucleation by abdominal section.

ELECTRICITY IN LACTATION.

Aubert (*London Medical Record*) alludes to the use of faradism in undeveloped mammary glands after parturition, and strongly advocates its value. In one instance two applications secured a full supply of milk, and other cases are noted.

Becquerel relates the case of a woman who, after eight days' suppression, was able to nurse her baby, and in whom the quality of the milk also was improved. The suppression resulted from intense mental emotion.

Pierron supports the above testimony by relating the notes of a large number of cases occurring since 1884 in his practice, in which electricity either re-established the function after suppression or induced it when absent after normal labor.

As heretofore stated, we have found static electricity always reliable as a galactagogue after the failure of all other procedures; but faradism will, of course, be available in any case where electricity is indicated. To be efficacious the treatment must be prompt and thorough, both breasts being included in the circuit at each sitting.

ELECTRICITY IN TEDIOUS LABOR, AND IN POST-PARTUM HEMORRHAGE.

The patient, a primipara, 23 years of age, suffered with albuminuria and excessive œdema. Uterine contraction was feeble at first, and then entirely absent. After twelve hours of fruitless effort to establish pains, an interrupted current was used, and labor terminated satisfactorily. Some two hours later hemorrhage occurred profusely, and, failing with vinegar, hot water, etc., the doctor again used the battery. Contraction was readily secured, and the bleeding did not recur.—*Guice de Fayette.*

ELECTROLYSIS IN ANEURISM.

Dr. Robert Abbe has recently reported the results of Barwell's method of treating aortic aneurism by the introduction of coils of fine wire and the subsequent passage of an electric current. In cases referred to in the practice of others, the tumors became solid, but the great defect appears to be in delaying until the sac is extremely thin and ready to rupture. Neither suppuration nor embolism has been noted thus far in any instance, and the formation of a firm clot is apparently obtained more certainly by this method than by the simple introduction of horsehair, catgut, or wire. As thoracic aneurisms are certain to progress, would it not be well to try the electrolytic plan as here described before the tumor has grown much, and whilst its wall is firm? The operation is within the ability of any practitioner owning a battery.

Obelar relates a case of aortic aneurism with horribly painful angina, in which galvano-puncture with twenty cells was employed. The needles were separated about one inch. The dysphagia was relieved, the general health renewed, but the tumor was only restrained from growth for a month.

Brancaccio relates a similar case in which four applications enabled the patient to return to his work. Dying from pneumonia three years later, a post-mortem disclosed a sacciform dilatation the size of an orange, completely filled with a firmly-organized clot, which could not be penetrated by the finger. The wall of the aorta was elsewhere sound, and in this instance the cure by electrolysis was proven. —*London Medical Record.*

DANGER OF ELECTRICITY IN OPIUM-POISONING.

In a paper read before the New York Academy of Medicine recently, Dr. Andrew H. Smith referred to the application of electricity to the phrenics in the neck in severe opium-poisoning. Dr. W. H. Thomson warned those present against in-

* See New York Medical Record, August 13, for latest report by Apostoli.

discriminate electrical applications about the throat, as did also the late Dr. Gasper Griswold. In a contribution elsewhere* we adverted to the necessity of care in direct electrization of the heart, and our remarks were based on known instances of improperly-conducted applications, in some of which serious damage was done. The danger in such cases is specially to be guarded against in dispensary and hospital work, in which the resident-physicians have had little practical experience with electricity, and the safest plan then is to gently stimulate the thoracic muscles by rapid labile applications, with an occasional touch over the solar plexus. In either instance one pole may be placed at the nape of the neck, and the other used as indicated. Electricity is not nearly so serviceable in opium-poisoning as the general opinion holds it to be, and, although we have frequently used it with advantage, we value the usual antidotes much more.

ELECTROLYSIS IN VASCULAR NÆVI.

Pitoy has obtained very satisfactory results in this form of dermic lesion through galvano-cautery, and with but little cicatricial marking. He advises the use of small platinum needles, and always makes the distance between the points of entry and exit not more than eight millimetres. When a distinct white zone is produced between these points the needle is withdrawn. If removed sooner, hemorrhage is liable to ensue. (*Annales de Derm. et de Syph.*, vol. viii. No. 1.) The reason why disfiguring scars so often result from cautery in nævi, in our opinion, is that too much electric force is used, and bleeding is produced by inserting the needles too deeply and removing them before the characteristic white surface is produced. The needles should also not be too fine, as it is difficult to induce whitening over a sufficiently large area at one sitting unless they are thick, and ulceration likewise is more apt to follow cautery with very small puncture at high heat.

GALVANO-CAUTERY IN SALIVARY FISTULA.

Dr. George Buchannan reports in the *Glasgow Medical Journal* the case of a lady suffering with a fistulous tract following an enormous carbuncle of the neck below the ear. The incision made left a sinuous tract unhealed for thirteen years, through which saliva flowed at each meal during mastication. The whole length was cauterized by the loop, and it healed firmly in two weeks, with little scar.

TREATMENT OF ENLARGED TONSILS.

Drs. Knight and Robinson, of New York, advocate strongly galvano-cautery in enlarged tonsils, with special reference to cases promising much hemorrhage. The former obtains definite cures with few sittings, although the rule is that the process is slow in most hands. Our plan for a long time has been to paint the tonsil with strong carbolized iodine before puncture, and to go into the centre of the gland in half a dozen places at each operation, allowing three days to elapse between dates. Neither hemorrhage nor sloughing has ensued, and we believe the method a good one where the patient objects to cutting or where bleeding is feared. Cocaine is also used of late.

ELECTRICITY IN ANGIOMA.

Dr. Julian Alvarez speaks very favorably of electricity in the treatment of angioma, and, using Onimus's apparatus, he plunges the positive electrode into the tumor, whilst the negative is moved about either over the mass externally or as close to it as possible. He gives excellent results in a large number of cases.—*Revista Balear.*

HYDRO-ELECTRIC BATHS IN NERVOUS AFFECTIONS.

Dr. R. Wagner, of Giessbach, describes several cases of neurasthenia, cardiac neurosis, etc. (*British Medical Journal*), in which his conclusions are that bipolar baths (galvanic and faradic) have these advantages:

"1. They possess special power as sedatives in excitable patients of neurotic tendency.

"2. Sleep, appetite, and the general tone are improved more readily thus than in any other method.

"3. The pulse-frequency being diminished during the baths, they are therefore to be strongly advised in angina pectoris and other cardiac neuroses."

Even were electric baths of value in any case whatever (which we doubt, beyond the effect on the imagination), the employment of them in angina would be fraught with danger, and the unavoidable delay in preparing the bath in acute at-

* Review of Progress in Medical and Surgical Electricity. Philadelphia Medical Times, July 10, 1886.

tacks would be criminal. Nitrite of amyl is the remedy, and arsenic in the intervals is better than electricity in any form.

FARADISM IN CHRONIC LARYNGITIS.

In persons who as vocalists are obliged to use their voice before thoroughly cured, faradism is found by several specialists to be of special value. At the recent meeting of the American Laryngological Association this point was sustained by several speakers. In conjunction with mild astringent sprays some four hours before using it, the voice is readily toned up by faradism, although complete rest is advisable after the emergency is past.

STATIC ELECTRICITY IN THE TREATMENT OF DISEASES OF THE SKIN.

For the past year Dr. Frank B. Carpenter, of New York, has been using static electricity in the treatment of diseases of the skin. He has found it particularly useful in diseases of the skin of neurotic origin. In seven consecutive cases of alopecia areata treated by that method exclusively, the hair ceased to fall after a few applications, and new hair soon commenced to grow. The more recent the cases, the more rapid was the improvement. The duration of the disease in these cases varies from three months to eighteen years. The youngest patient was ten years of age; the oldest was thirty-eight.

In the treatment of three cases of alopecia præmatura by the same method, the results were sufficiently encouraging to warrant the belief that static electricity will not only prevent the baldness, but will restore the hair when it has already fallen.

In five cases of zoster treated only by the static current, the neuralgic pains were much diminished. It appeared to check the eruption, preventing the formation of vesicles when used early in the disease, and causing them to desiccate, thus forming a protective covering when the vesicles had already formed.

In several cases of severe pruritus genitalium, more satisfactory results were obtained than by any other method of treatment he has used. He has found it of use in the treatment of lichen planus and dermatitis herpetiformis.

The reviewer has during the last eight months been trying a series of experiments with static electricity and faradism in alopecia dependent principally on debility consequent upon fevers. So far success has been encouraging, much more so than that otherwise secured by stimulating hair-tonics. He has not found it necessary to cut the hair or to shave the scalp, as is usual where the hair falls profusely. A rheophore saturated with distilled extract of witch-hazel is used on the scalp, and it is closely applied, the spark occurring at the discharging-rods of the machine.

Reference has been made in these columns before as to the value of electricity in pruritus and in herpes zoster.

THE PROJECTION OF PARA- AND DIA-MAGNETIC MOVEMENTS OF LIQUIDS.

Ricco gives the following simple method of illustrating the different effects produced by the electro-magnet upon para- and dia-magnetic liquids. The rays from a candle are collected by means of a convex lens and reflected from the plane surface of the liquid to be tested, the image being received on a white screen. The current is then turned on. If the liquid is amagnetic (or neutral), no effect is produced; otherwise the image is scattered or confused. If the liquid is para-magnetic, the image can be caused to reappear by bringing the screen nearer the liquid surface or by removing the lens, and the new image will then be drawn out, indicating the cylindrical formation of the liquid surface. When the liquid is dia-magnetic, the image reappears on removal of the screen to a greater distance or upon the substitution of a shorter focus-lens, thus proving the convexity of the liquid surface.—*L'Elettricita.*

GALVANISM IN EXOPHTHALMIC GOITRE.

The patient, æt. 28, a nurse, under the care of Dr. W. B. Hadden, of London (*Braithwaite*, July), with extreme exophthalmos and much suffering from pressure on the trachea, had been unsuccessfully treated by drugs. The current (galvanic) was passed from the nape of the neck to the thyroid and eyeballs—strength not stated—for ten minutes twice daily. The cure occupied a month, and no return of the disease was noted after prolonged observation. In a paper by the reviewer* on this subject, the efficacy of galvanism

* Philadelphia Medical Times, April 23, 1881.

in severe cases was shown, and none of the cases narrated in that paper have had a return of the disease in the six years which have passed. Nothing except electricity is used in such cases, provided the patient is strictly under our care; and several interesting examples have been treated since the publication of the paper referred to. The method used is: positive to the cervical pneumogastric, negative to the solar plexus; thirty to seventy-five milliampères for fifteen minutes daily.

WAKING NUMBNESS.

Within six months past a few cases of this rare affection have been reported, and to these may be added two coming under the charge of the reviewer.

The first, a gentleman of decided nervous type,—a bank clerk,—was troubled for some four years, at first at intervals of a month or more, but recently every two or three days. The anæsthesia covered the abdomen and one-half of the right lateral thorax, and the sensation was that of deadness. The skin was decidedly benumbed as to sensation, and sharp pricks with a pin were not felt if the eyes were covered. The phenomena commenced on waking, and lasted from ten to forty minutes. No gastric or renal disorder was discovered. The patient was referred to me for electrical treatment by his family physician.

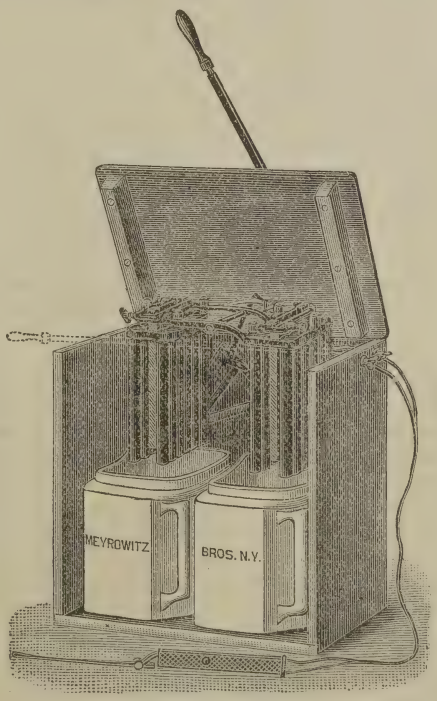
The second case was that of a young lady in my own practice. She was apparently in vigorous health. The disorder had lasted three weeks when I took it in hand. The sensation was such as prevails after pressure upon any large nerve. She was not anæsthetic so far as painful tests were concerned, and there was hyper-excitation after the disappearance of the numbness. The sensation was confined to the thigh and hypogastric region of the left side. It lasted about ten minutes after rising in the morning. In this case pressure over the left ovary at any time precipitated an attack, which, however, would last some five minutes or less. She always slept with the limbs extended: hence pressure could not be the determining cause whilst asleep.

Galvanism cured both patients,—central applications with the male, and positive to the ovary with negative to the foot in the female. From fifty to one hundred milliampères were given for fifteen minutes daily in each case. The first required a month's treatment, the second ten days only.

NEW GALVANO-CAUTERY BATTERIES.

Mr. A. F. Fleishmann, of this city (1812 Market Street), has devised an ingenious modification of the Bunsen type for cautery purposes. The apparatus consists of six cells with multiple plates, and the commutator couples either for quantity or intensity as may be desired. Any degree of immersion is attainable by a ratchet mechanism, and either or all of the series of plates may be employed at one time. A careful test maintained the cautery electrode at a definite heat for two hours continuously, and the battery requires very little attention.

Messrs. Meyrowitz Bros., of New York, have presented a cautery apparatus with novel features. The cells are accessible



from the front of the case: they are readily emptied without spilling, from their possessing a handle and lip, and the plates are submerged or raised by an ingenious lever-movement. The action is very prompt, and polarization is avoided to a great extent. Of the many new types, this is an exceedingly desirable one for

galvano-caustic purposes or where quantity-currents are desired.

NEW BIPOLAR ELECTRODE.

At a late meeting of the Paris Academy of Medicine, M. Dujardin-Beaumetz presented an electrode devised by Professor Apostoli for localizing currents. The olivary point is carbon, divided in the median vertical line by a thin insulating strip of gutta-percha, and from its construction it is incorrodible. It is evident, however, that no such use as that of a cautery instrument could be made of it, as the insulation, whether of vulcanite or gutta-percha, is readily destroyed by low heat.

INCANDESCENT SEARCH-LAMP.

Dr. Dent, of St. George's Hospital, has had Messrs. Woodhouse & Rawson, the eminent London electricians, make for him an incandescent lamp of high power within small compass, which is specially valuable in abdominal surgery. The low temperature allows the globe to be placed within the cavity, so as to render translucent the omentum, the bowel, etc., and thus add to the sense of touch that of sight. One side of the globe is frosted to prevent dazzling, and the bulb and conductors can be bathed in sublimate or other antiseptic solutions with impunity.

THE TOXIC AGENT IN CASES OF POISONING BY ICE-CREAM.

BY GEORGE S. HULL, M.D.

DURING the past few years cases of ice-cream poisoning have been quite frequently reported, and there have been numerous investigations into the cause of the trouble. As far as the writer has been able to follow the literature of the subject, no *one* theory seems to be sufficiently plausible to be accepted as correct. Among the numerous reasons given by experts the following are most noteworthy: keeping the milk or cream in unclean vessels, especially in copper cans; exposing it to a polluted atmosphere; obtaining it from cows that have been improperly fed or cared for; and, finally, adding corn-starch, etc., to it, and allowing fermentation to set in, thus generating ptomaines by reason of the micro-organisms present. The latest and most generally liked theory is that advanced by Professor Vaughan, whose careful study of tyrotoxicon has given him such deserved prominence. The interesting history of the discovery of this poisonous compound, its simple manner of isolation, and the skilful and painstaking analysis of it, which proved it to be diazobenzol, are all too well known to be repeated. However,—and without attempting to array myself against this theory,—I wish to mention a few facts which seem to militate against the supposition that ice-cream poisoning is most generally due to the presence of this ptomaine.

The peculiar ferment or micro-organism which generates tyrotoxicon is not yet known, and even the precise conditions under which it develops have not yet been ascertained. It is true that milk containing the micro-organism will, when added to pure milk and kept at a temperature of about 98° with a limited supply of air, readily inaugurate the process which generates this particular ptomaine,—which, however, is said to be ephemeral, further fermentation breaking it up into other compounds; also, a temperature much less than that of boiling water destroys it, and a freezing temperature, while not fatal to its production, certainly should not be favorable to the micro-organisms which are said to generate it.

It would seem reasonable that milk, which is consumed in such vast quantities, and which is so carelessly handled as regards proper temperature, clean vessels, and pure atmospheric surroundings, should very frequently be put in the very conditions (we know not precisely what they are) which would favor the development of the micro-organism and the consequent production of the tyrotoxicon; and then that very often it should be taken into the stomach just when the poisonous ptomaine was most abundantly present, and before it could undergo further change and become converted into other and perhaps less harmful compounds. All this seems highly probable, and the result should be the quite frequent poisoning of people from drinking milk. Now, whether this actually be the case or not, the fact is that the *reported* cases of ice-cream poisoning are out of all proportion to the ratio of consumption of milk to ice-cream,—unless we believe cholera infantum to be due to the ingestion of tyrotoxicon, as has been suggested.

Let us see whether the conditions which are so favorable to the formation of tyrotoxicon in milk obtain in any like degree

in the manufacture of ice-cream. It is well known that most ice-cream mixtures are boiled before being subjected to the freezing process, thus destroying any micro-organism present; this is the case particularly when corn-starch, gelatin, etc., are components. After the mixture is subjected to the low temperature of freezing, the likelihood of the formation of germs is very much lessened, although this condition may not be fatal to micro-organisms which may have been developed previously and not destroyed by boiling. So we have reason to believe that the conditions which so much favor the formation of tyrotoxicon in milk do not exist in nearly so great a degree as regards ice-cream. I am aware, however, of the fact that ice-cream, after being sterilized by heat and put into the freezer, may be allowed to melt, and after a time be re-frozen, thus being placed in a condition which may favor the production of tyrotoxicon; or the rancid butter adhering to some carelessly-cleansed cans may start the process by reason of the butyric acid present.*

I merely present the above brief reasoning to bring out the anomalous condition of affairs which must hold if, after eliminating cases of poisoning in which foreign poisons have been maliciously added to ice-cream, tyrotoxicon should be urged as the sole cause of the trouble; and I repeat that, considering how little ice-cream is consumed compared with the quantity of milk used, the ratio of the cases of poisoning seems out of all proportion. This thought is what led the writer to devote some time to the study of this interesting and important subject, and to the performance of numerous experiments with various ice-cream mixtures,—a brief notice of which has already gained publicity.

As there could be found no reports of investigations as to what went on within the freezer during the process of freezing, it was determined to confine the study to this part of the subject; to examine closely the modern ice-cream freezer, and to see if the ice-cream mixture, after having been proved to be pure and innocuous before being put into the freezer, *could generate any poisonous substance during and after the process of freezing.*

Upon looking into the construction of the modern ice-cream freezer, I found it, with very slight exception, to consist of a zinc-coated paddle and a tin or copper can; the bottom of the can was in most cases heavy iron coated with zinc. Here, it struck me, was a first-rate galvanic cell: zinc the positive element, and tin or copper the negative. The elements also were in contact. It was only necessary to find out how good an electrolyte the ice-cream mixture as variously made was, in order to ascertain the proportion of zinc dissolved in each case. A miniature ice-cream freezer was constructed and numerous experiments performed. Instead of the dissimilar metals being in direct contact, as in the freezer, they were connected by a copper wire and a moderately sensitive (astatic needle) galvanometer introduced into the circuit. It was evident that if the galvanometer-needle was at all deflected it would indicate that a current of electricity was passing, due to chemical action between the zinc and the mixture within the freezer; that the zinc was being dissolved; and, further, the amount of deflection would indicate the degree of chemical action, *because the current causing the deflection would be in proportion to the amount of chemical action.* By this means we could find out which ice-cream mixtures would dissolve the most zinc, and so become the most dangerous to the consumers.

In order to institute a comparison between the different ingredients used in making ice-cream, pure cream was first tested. At 32° F. it caused a deflection of seven degrees, showing that the zinc was being dissolved to some extent. The following table will give an idea of some of the results obtained:

Distilled water	No deflection.
Hydrant water	8 degrees.
Cream, sweet (unfermented)	7 "
" sour (fermented)	90+ "
Milk, sweet	40 "
" sour	90+ "
Equal parts of milk and cream, sweet	25 "
" " " sour	90+ "
" " " with sugar and vanilla—sweet	58 "
Equal parts of milk and cream, with sugar and vanilla—sour	90+ "
Equal parts of milk and cream, with sugar and corn-starch—sweet	45 "
Equal parts of milk and cream, with sugar and corn-starch—sour	90+ "
Equal parts of milk and cream, with sugar and eggs and corn-starch—sweet	80 "
Equal parts of milk and cream, with sugar and eggs and corn-starch—sour	90+† "

* Professor Vaughan claims that the bacillus butyricus, or some ferment which develops along with it, will inaugurate the process.

† By 90+ is meant that the needle is deflected to a right angle to the current, and the only comparison that can be made between mixtures which cause such amount of deflection is by noticing the force with which the needle swings past this point. By using a less sensitive instrument these acid mixtures could readily be compared.

The fruit ice-creams caused deflections of from fifty to ninety plus degrees when sweet (unfermented), as also did the water-ices. I have endeavored to embody in the above table the most common forms of ice-cream mixtures, so as to give an idea of what can be found out by using the galvanometer in this way. It will be noticed that pure cream has the least action upon the zinc, and if ice-cream, as its name leads one to infer, were *always* made from *pure cream*, there would be but little cause for alarm.

These figures go to show *most positively* that the ice-cream which causes most deflection of the needle is the one which dissolves most zinc, and hence is the one most likely to cause poisoning. Another conclusion easily arrived at is that the longer the zinc is in contact with the material in the freezer the larger the quantity of the zinc dissolved.

Now it is in order to explain why, if zinc is always dissolved in some degree by ice-cream as made in the modern freezer, ice-cream poisoning is not more general, and why it breaks out violently at times and produces wholesale poisonings. I would volunteer the following. Ice-cream is ordinarily frozen in from ten to thirty minutes; then the paddle taken out and the mixture "packed" and set aside to harden. This, unless the mixture is quite acid, is too short a time in which to dissolve very much zinc, and so generally no bad results follow. And yet there are not a few persons who complain that ice-cream but seldom agrees with them; it disorders their sensitive stomachs, they know not why. However, when the mixture is put into the freezer warm and allowed to stand awhile before being frozen (high temperature being more favorable to the chemical action); or when a number of freezers are prepared and frozen one after another (allowing the zinc in the last to be a long while in the mixture); or when the mixture is "turned" (one manufacturer told me he could make smoother and better ice-cream if the mixture was "a little bit sour"); or when acid fruits are present; or when the ice-cream has been allowed to melt and partially ferment, and then have fresh material added to it and be refrozen; and *especially* when salt by any mishap gets into the freezer (I have been told that small quantities of salt are sometimes added to certain ice-creams to improve the taste); then we have favorable conditions for the formation of poisonous salts of zinc.

In looking into the recorded cases of ice-cream poisoning, it is noticeable that most of them have occurred at picnics, at banquets, on holidays, etc. For picnics the ice-cream is generally made the day before, and the paddle, it is likely, allowed to remain in over-night, so as to refreeze in case of too much softening; thus allowing plenty of time for the chemical solution of the zinc. The large manufacturer may have a superabundance of orders for a holiday; he makes quantities of the ice-cream mixture and puts it into his freezers, there to await its turn at having the power applied for freezing, and the family who get the contents of the last freezer are in great danger of being poisoned. It has been proved long ago that well- or spring-water will dissolve small quantities of zinc, especially when chlorides are present.*

Milk also has been shown to act upon the zinc vessels which contain it,† and it has been the object of this paper to direct attention to the fact that dangerous amounts of zinc may be dissolved, *owing to the faulty construction of the modern ice-cream freezers.*

These facts go to show that in order to prevent metallic matter from being dissolved, no metals forming poisonous salts should be placed in contact and kept in any liquid intended to be taken into the stomach; also, that any metallic vessel which is to hold liquids for human consumption should be of one kind of metal, and that in its purest state, as other metals, if present in it, will set up local action, and thus cause a more rapid solution of the positive element. Indeed, in order to be thoroughly safe, all metals which form poisonous salts with ordinary acids should be avoided in the construction of such vessels.

While upon this theme, I might direct fresh attention to the fact that the harmless (?) soda-water is guilty of dissolving deleterious quantities of lead, etc. Beer, also, which is kept in zinc-lined vessels

* Zieurek found in water contained in a zinc cistern no less than one drachm of zinc to the gallon. The same water showed only six grains of sodium chloride to the gallon.

† M. Schaufféle, by keeping milk in a zinc vessel for fifteen days, found that the zinc was dissolved to the extent of three hundred and fifty grains to the gallon; while, when kept for the same length of time in a zinc-coated (galvanized-iron) vessel, four hundred and eighty grains to the gallon was the amount dissolved. This latter fact is significant in this connection.

with copper or brass spigots may add sufficient mineral poison to the other poisons it already contains to become extra-hazardous. Even the innocent buttermilk may suffer serious contamination in the same way.

Dentists, all unconscious of the distinction, may, I have thought, be called "practical electricians," because they are constantly putting small galvanic cells into the mouths of their patients. Plugs of gold, silver, and "amalgam" (tin, silver, and zinc rubbed up with mercury) are put into the same mouth, to be bathed by the saliva (a fair electrolyte), thus constituting galvanic cells, and frequently the dissimilar metals are brought into contact, the result being a small current of electricity (sometimes strong enough to be felt) and the solution of some metal, which is generally swallowed; but this is probably too trifling to merit much attention.

Fruit-cans have tin and lead (solder) in contact, and as these are exposed to the juices of acid fruits we may readily estimate the danger; we know something of the sickness caused by canned fruits. In order to show the mischief worked in other directions, I will mention one of many instances. Machinists often complain of their inability to keep copper or brass tubes which are fitted into iron boilers perfectly tight; the steam in time will leak out. Here we have iron and copper as the two elements, and, if the water in the boiler contains saline matter, we have a galvanic cell on a small scale, but sufficient in time to eat away enough metal to cause a troublesome leak.

In conclusion, I desire to state that there is no intention to claim that ice-cream poisoning is *always* produced in the way I have detailed. I merely wish to offer the thoughts of this paper as additional to what has been advanced on the subject. The tyrotoxicon theory will help explain those cases of ice-cream poisoning in which the mixture has not been boiled or has been allowed to melt after having been frozen; and the theory which the writer has outlined may help explain what remains.

It might be well to add that where tyrotoxicon is present the zinc salts should the more abound, as the ptomaine is developed in an acid mixture, and acid fluids are most favorable to the solution of zinc.

CHAMBERSBURG, PENNSYLVANIA.

REMARKS ON THE BACILLUS OF LEPRA, WITH MICROSCOPICAL PREPARATIONS.

BY J. P. CROZER GRIFFITH, M.D.,*

Assistant Physician to the Hospital of the University of Pennsylvania.

THE specimens from which the preparations shown this evening have been made are chiefly from a case which occurred in Demerara, but of whose clinical history I can learn nothing. There is also a microscopical slide prepared from leprous skin which I obtained in Vienna.

Some understanding of the pathological histology of the disease is necessary before studying the nature and distribution of the micro-organisms.

The infiltration of lepra consists of granulation-tissue, under the microscope much resembling that of lupus, except that it is not so much divided into nests as in the latter affection, nor is there so great a supply of blood-vessels. The deposition of lymphoid cells takes place primarily in the corium, and extends thence along the course of the blood-vessels towards the surface and into the deeper layers of the subcutaneous tissue. The production of giant-cells and the occurrence of retrograde metamorphoses are to be observed both in lepra and lupus.

A preparation from one of the nodules of the Demerara case has been stained with hæmatoxylon and is exhibited under one of the microscopes on the table. It will be seen to be composed of an accumulation of lymphoid cells covered by a thin epithelial layer. There are comparatively few blood-vessels to be found, and the tubercle presents an almost uniform appearance throughout, except for the scattered bands of connective tissue which divide it into poorly-defined lobules. The lymphoid elements are situated in an alveolar net-work, and in many places giant-cells may be observed. A very similar appearance is that of a transverse section made from the terminal phalanx of one of the fingers, in which even the bone has been destroyed by the disease. This preparation is also exhibited under one of the microscopes, and the uniform infiltration of all the tissues below the *rete Malpighii* will be noticed. Around the blood-vessels the cells are gathered in greater numbers,

* Communication read before the Philadelphia Pathological Society.

often forming concentric nest-like groupings. The walls of the vessels are frequently thickened by the infiltration, and a partial obliteration of the lumen is often to be observed, the latter being caused by a proliferation of the endothelial lining.

Other sections of the finger and of the nodule have been double-stained in order to show the *Bacillus lepræ*. The method adopted was the well-known one of Ehrlich for staining tubercle-bacilli, using either fuchsin or gentian violet,—followed in the first case by methyl blue or by the sulph-indigotate of potash, in the second case by Bismarck brown. The best results were obtained with the fuchsin and methyl blue.

The bacilli are usually described as slender, rod-shaped bodies of a length equal to one-half or one-third the diameter of a red blood-cell, often joined end to end in short chains or gathered in bundles, almost invariably lying in the great "lepra cells," and only rarely to be seen in the intercellular tissue. Under one of the microscopes I have placed a slide from the specimens of leprosy obtained in Vienna. This exhibits bacilli corresponding with the usually accepted description. Here the huge lepra cells, crowded with the microbes, are shown to perfection, and no scattered bacilli are to be seen. But in the Demerara specimens shown this evening the micro-organisms are spread throughout the whole tissue, including even the epithelial layer, though here they occur but sparsely. That they are to be found among the epithelial cells, and even in the hair-follicles and in the hairs themselves, had been denied by most writers, but has since been affirmed by Unna,* and later by Touton† and Neisser. You will be able to see them very distinctly among the epithelial cells in the specimens shown this evening. Elsewhere in the tissue they appear to a slight degree massed in regularly round or oval lepra cells, but chiefly free, and either isolated or in irregularly-shaped groups of various sizes. Their occurrence to so great an extent free in the tissues has been claimed by Unna,‡ but has been hotly contested by Hansen, Neisser, and Touton. If true, it removes one of the most characteristic differences between the arrangement of the bacilli of lepra and those of tuberculosis. Unna declares that the lepra-cell never contains a nucleus, and that it is, in fact, nothing more than an aggregation of bacilli held together by mucoid material. The appearance of the bacilli in the specimens from Demerara indicates the probable accuracy of this view. There is too much variation in the size and too great an irregularity in the shape of the aggregation to warrant the belief that they are situated in a cell, and neither nucleus nor cell-wall can be detected.

Unna's method of preparation was somewhat peculiar. The sections, after being stained and cleared in oil, were dried with blotting-paper and then *over the flame* until the oil was evaporated, and were then mounted in balsam. Other specimens were stained, then transferred directly from water to a cover-glass, warmed over the flame to absolute dryness, and mounted in balsam, thus avoiding the use of oil. These methods are said to show the bacilli in unusual numbers. Hansen§ and Neisser‖ believe that Unna's method destroys the cells, and that on this account, therefore, the bacilli have appeared to lie free in the tissue and lymph-spaces. Hansen does not deny that they may lie in the lymph-spaces, but thinks that when properly treated they will be found *in cells* in these spaces. He brings forward other arguments to support his view, among others that the bacilli can never be found in the blood. Neisser makes the same statement. Kobner, however, declares positively¶ that they do occur both in the white blood-corpuscles and in the serum. He finds them free in the intercellular tissue as well as in lepra cells, but never in the epithelial layer.

Although not fully prepared to express an absolute conviction, yet the appearance of the specimens exhibited this evening makes me inclined to adopt the view of Unna with regard to the position of the bacilli in the tissue. I have avoided the special methods of preparation which he employed, and can see no reason why those which I have used should destroy the lepra cells, if indeed these bodies really are of a cellular nature. It is a curious circumstance, too, that while the specimens from Vienna show bacilli in lepra cells alone, those from Demerara

* Deutsch. Med. Zeit., December, 1885, S. 14.
† Virchow's Archiv, civ. 381.

§ Virchow's Archiv, ciii. 388. ‖ Ibid., 355.
¶ Virchow's Archiv, lxxxviii. 282.

reveal scarcely any such structures, but are crowded with microbes lying free in the tissues. They have been prepared in precisely the same manner. Whether it is that these cells, or masses of mucus, or whatever they may be, at some time in the course of the disease burst, or in some way become destroyed and spread the bacilli broadcast, I do not know, but it would seem at least possible. Dr. Lyell, of China, says, in a personal communication, that he easily finds the bacilli in the lymph from the leprous vesicles. This seems to be a proof that, even if Hansen's view is correct regarding the position of the microbes in cells in the lymph-spaces, these so-called cells must break down very readily and set the bacilli free.

TRANSLATIONS.

Evolution of the Tonsils.—At a recent meeting of the Paris Biological Society, M. Ed. Retterer made the following communication concerning the evolution and constitution of the tonsils in the human subject. Th. Schmidt, Kölliker, His, etc., explain the formation of follicles in the tonsils by the differentiation of the mesodermic cells. According to these authors, the epithelial elements do not take any part in the formation of the follicles. M. Retterer concludes from his observations that this explanation is erroneous, and gives the following description of the evolution of the tonsils in human beings, from the fœtal period to an advanced age.

In a fœtus of three and four months old, the initial phenomena are more particularly the folding back of the epithelium of the isthmus of the throat and the penetration of several invaginations into the chorion of the mucous membrane. As these invaginations become longer a central space is created; moreover, the epithelium with which they are invested remains stratified, and in its evolution gives rise to epithelial globules which undergo all the modifications of keratinization. The chorion becomes thicker where it surrounds these globules, owing to the proliferation of the mesodermic tissue and the accumulation of young connective-tissue cellules, which form cellular laminæ which are traversed from the beginning with numerous blood-vessels. Towards the fifth month the primitive involutions give rise to a series of epithelial buds which appear on their periphery, and principally on their lowest extremity. These buds press from all sides into the mesodermic laminæ, which continue to be the source of an active growth. When the epithelial buds are cut perpendicularly to their axes, they present the aspect of cylinders joined by one of their extremities to the primitive invagination; when they are transversely cut, they present the aspect of epithelial masses surrounded on all sides by young connective tissue. These evolutionary characteristics, which at the onset resemble those accompanying the formation of the nipple, are continued until birth takes place, when the whole tonsillar formation begins to appear on the surface of the isthmus of the throat.

At the age of two or three years, the aspect presented when the tonsils are cut as above described differs considerably from that presented when they are cut in the preceding evolutionary stages. The primitive involutions begin to take the form of cryptæ or diverticulums which connect the interior of the tonsillar mass with the isthmus of the throat. The terminal buds become gradually separated from these diverticulums through the interposition of the mesodermic laminæ between these buds and the involutions from which they proceed. This circumstance is analogous with that observed in the separation of the neuro-axis from the epidermis, and with the manner in which the crystalline and the auditine vesicule are isolated and detached from the corneal layer through the interposition of a mesodermic layer.

Towards the age of from three to six years, masses which are purely epithelial rarely remain in the connective tissue. The epithelial masses have not disappeared through resorption or degeneration; they are the centre of an active proliferation. The epithelial buds contiguous at the outset to the connective tissue are gradually penetrated from their periphery by cells and fibres of cellular tissue, which are inserted between the epithelial tracings and separate these from each other. An analogous phenomenon takes place in the development of the liver. At this period, which is characterized by a uniform appearance of the tonsillar tissue (*infiltration diffuse*), closed follicles (*follicules*

clos) begin to develop in the tonsil. These follicles are grouped in one or more series around each diverticulum, which is the remnant of the primitive involution and represents the centre of a tonsillar lobe. The lobes are separated from each other by a septum composed of connective tissue. The appearance of closed follicles results from the more noticeable development of the connective tissue in the space which existed at the outset between the epithelial buds. From thence the connective-tissue stroma extends to the centre of the buds, whilst the fibres of this stroma, being stretched out, form a net-work with larger interstices. The blood-vessels follow this principle and exhibit a similar disposition.

In advanced age the closed follicles diminish in size, and even disappear in certain places. The immediate cause of this phenomenon is the increased number and thickness of the connective-tissue trabeculæ, which invade the mass of closed follicles and give a uniform aspect to the tonsillar tissue. At the same time, empty spaces presenting the form of alveoli are observed. Of these, the most recent enclose cellular *débris*. Under the influence of reagents crystals of margarin appear. This is the final stage of the evolution of the tonsils, characterized by the fatty degeneration of the elements themselves and by hypertrophy of the connective-tissue stroma.

The development and evolution of the tonsils in human beings may be summed up in the following manner: (1) the production of epithelial convolutions and increased thickness of the chorion; (2) the formation and subsequent detachment of the terminal buds; finally, the penetration into each element of the mesodermic stroma and the ectodermic tissue. The existence of follicles only lasts while the separation of the connective tissue is more accentuated in the peripheral portions than in the central portions. The retrogressive stage follows closely upon the fibrous transformation of the stroma, and gives an alveolar appearance to the tonsillar tissue.

Exhalations of Carbonic Acid in Infectious Diseases.—At a recent meeting of the Académie des Sciences, M. Arloing presented some remarks on the exhalation of carbonic acid in infectious diseases determined by aërobic microbes and anaërobic microbes. If the microbes are aërobic, they rob the blood-corpuscles of their oxygen, and deprive the tissues of their necessary comburant or agent of combustion (bacillus anthracis, microbe of chicken-cholera).

If the microbe is anaërobic, and acts as such in the organism, then oxygen should be a hinderance to the manifestation of its properties (gangrenous septicæmia). Between two animals which succumb, one through the inoculation of the aërobic microbe, and the other through the introduction of the anaërobic microbe, important differences are met with in respect to the intensity of respiratory combustion.

The diseases which M. Arloing chose for these experiments are affections which sometimes attack the human species: malignant pustule and gangrenous septicæmia. In these two diseases M. Arloing found that the quantity of carbonic acid exhaled diminished during the course of the malady, and especially during the few hours before death. In the case of malignant pustule the modification appeared to begin with the first effects of inoculation; while in gangrenous septicæmia there is for a few hours a slight augmentation in the quantity of carbonic acid exhaled. In both cases there is a diminished respiratory combustion.

A Case of Total Extirpation of the Uterus and Nephrectomy at One Sitting, with Recovery of the Patient — J. Schmidt reports in the *Münchener Med. Woch.* (1886, No. 40) the case of a woman, 49 years of age, upon whom the operation of extirpation of the uterus for malignant disease was undertaken. It was found that the posterior vaginal wall, the submucous tissue, and the right parametrium were infiltrated. After a tedious operation the uterus was removed, when it was discovered that with it had been taken away a portion of the right ureter about an inch in length. It was decided then to remove the right kidney by lumbar incision. The patient made a good recovery. The author recommends in similar cases, when the ureter has been injured, to proceed at once to extirpation of the kidney, and not to attempt to stitch the ureter in the vaginal wall, since the result would be gangrene or diphtheritic deposit in the vagina, from the constant flow of urine. — *Centralblatt für Medicinischen Wissenschäften*, 1887, No. 31.

EDITORIAL.

CHLORAL HYDRATE.

THE death of a lady prominent in society of this city, following the administration of chloral, to which she had been accustomed to resort for the relief of nervousness, has shocked the entire community, and seems to call for a repetition of a warning of the danger of this drug. Unlike other agents of the class of narcotics, its effects seem not to be proportioned to the amount: what might be given at one time with perfect safety becomes on another occasion a lethal dose. This is partially explained by the manner in which it acts upon the nerve-centres. In the first place, it has a sedative influence directly upon the ganglion cells of the cerebral hemispheres and spinal cord, and ultimately upon the medulla; in the second place, it exerts an hypnotic influence indirectly by reducing the blood-supply of the brain, owing to the general dilatation of the arterioles elsewhere throughout the body. In ordinary doses, and as the rule probably, the indirect effect of producing relative anæmia of the brain is the effect which is sought after and obtained; where larger doses are given the direct effect becomes more marked.

It has been repeatedly observed that chloral is a dangerous drug, since patients accustomed to its use may be thrown into a fatal coma by doses smaller than those which they had frequently previously taken with impunity. Even so small a dose as ten grains has caused the death of an adult; while others have recovered without ill effect after swallowing an ounce. It is strange that this peculiarity has escaped the notice of so acute a therapeutist as Ringer, who says that "it has been given for months apparently without any bad results," and has much to say in its favor; but he neglects to mention its great danger when habitually resorted to for insomnia or nervous irritability.

We have observed that in some cases the fatal doses have been taken just after a meal, the coma rapidly supervening and the fatal termination occurring suddenly. Possibly the chemical changes incident to gastro-intestinal digestion may explain the excessive and otherwise unaccountable narcotic effect from the dose which is ordinarily taken with impunity when the stomach is at rest. It has been determined, from experiments made by Amory, that chloral ordinarily does not undergo decomposition in the body, and consequently does not liberate chloroform in the blood, as Liebreich affirmed. It is worth considering, however, whether Liebreich's original hypothesis may not be correct in these exceptional instances. Since, in the presence of alkali, chloral is readily converted into chloroform and formic acid, this may also occur, if not in the blood, at least in the duodenum when chloral, mixing with the food, passes through the pylorus to come at once in contact with the highly alkaline bile. Under such circumstances, given the coexistence of a weak, dilated, or fatty heart, the liberation of an amount of chloroform too small to escape by respiration, or at least too insignificant to make its presence evident to the senses, might rapidly prove fatal. There may be other explanations for these very sad accidents that have occurred from small doses of chloral hydrate, but this one is at least sufficiently plausible to warrant us in warning our patients against taking chloral just after eating a hearty meal, or, indeed, at any other time, unless under the direction of competent medical advice.

The quality of the chloral should also be taken into consideration, and for medicinal purposes only pure recrystallized chloral should be used.

RHUS-POISONING.

THE Board of Health of this city has acted commendably in ordering the removal of poison-ivy from cemetery-grounds on account of the many cases of poisoning which have lately occurred. If a similar rule were made and enforced with regard to all public parks, it would save much annoyance and suffering. There is, it is true, a great difference in the individual susceptibility to the effects of the poison, the resulting dermatitis venenata being in some a trifling affair, in others seriously threatening life. A case was reported to the County Medical Society of this city some time ago in which proctitis and peritonitis resulted from extension of inflammation from the anus, to which a leaf had been applied after defecation while on an excursion in the woods. In some instances direct contagion has been traced, as where a physician, after employing himself in pulling up a few weeds in a cemetery, stopped to see a patient and dressed a fractured forearm on his way home. Both physician and patient subsequently suffered with acute dermatitis, which was supposed to be erysipelas by the latter.

Owing to the different degrees of effect produced, varying from nothing at all up to a very acute and extensive inflammation, an opportunity for exact comparison of the value of remedies is wanting; hence the number of specifics. The first indication seems to be to counteract the poison (toxicodendric acid) by the application of an alkali (sodium carbonate, bicarbonate, borate, or hyposulphite); and the second is to relieve the dermatitis by sedative and anodyne applications. The combination of carbolic acid with oxide of zinc ointment (in the proportion of twenty to thirty minims to the ounce) has answered admirably in checking the spreading inflammation and relieving swelling and pain. It has been suggested by a correspondent of another journal that the alkaline solution of sodium carbonate be applied by dipping a piece of bread in it and placing it over the inflamed area; subsequently, if it become dry, water could be dropped upon it; thus making it in effect a bread-poultice. As it is claimed that it certainly affords relief to the pain, it seems that this is a good suggestion.

A FATAL ACCIDENT DURING ETHER-ANÆSTHESIA.

THE daily papers of this city have recently given an account of a fatal case during the administration of ether. In the midst of an operation for the relief from hemorrhoids of a middle-aged man, under the care of Professor Agnew, the patient suddenly stopped breathing and could not be resuscitated, although it is claimed that the heart continued beating for several minutes after respiration had ceased. The coroner's physician, Dr. Formad, made an autopsy, and discovered evidences of long-standing inflammatory and degenerative disease in the brain and medulla oblongata. The lungs were not engorged, but were collapsed. Death was probably due to the immediate shock of the operation or excessive apprehension; the lesions found were sufficient to cause death under any unusual excitement or emotion, but they do not correspond with the usual effects of ether when taken in a toxic dose.

THE COOPER HOSPITAL, of Camden, was opened formally on the 8th inst. The buildings and grounds, both presented by members of the Cooper family, cost over one hundred and twenty-five thousand dollars. Nearly two hundred thousand dollars is invested in a permanent endowment-fund, and twenty thousand dollars more will soon be added by a bequest, at the expiration of a life-estate, devised by Mrs. Jane V. Chambers, deceased.

LEADING ARTICLE.

ON THE DEGENERATION OF NERVES.

WHEN a section is made in the continuity of a nerve, the peripheral extremity undergoes changes classed under the name of degeneration.

At a recent meeting of the Biological Society of Paris, M. Arloing made a valuable contribution to the study of the degeneration of nerves and the trophic nerve-centre. The nature of this phenomenon has been differently described. M. Arloing considers it sufficient to begin by studying the modifications which take place at the end of the central extremity.

M. Ranvier has demonstrated that this region is the source of the generation and progressive extension of the axis-cylinder, and these exposed cylinder axis-buds are the starting-point of the regeneration of the peripheral extremity. M. Vanlaired has confirmed these statements. M. Ranvier concluded that the development of nerve-fibres in a pathological state begins in the central nerve-cells. This author did not, however, accept as the explanation that the axis-cylinder, killed by section, acts upon the nuclei and protoplasm so as to increase the activity of these, as a fragment of necrotic bone acts upon the neighboring portions. He rather believed that the nerve exercises a moderating influence upon its own nutrition, and that this influence is suppressed, after section, throughout the entire peripheral extremity. M. Arloing considers this to be a gratuitous hypothesis, but believes it probable that the axis-cylinder becomes sphacelated after its separation from the cell from which it proceeds, and produces all the characteristics of necrobiosis. M. Ranvier based his opinion on the fact that the loss of excitability in the peripheral extremity coincides with the segmentation of the axis-cylinder by the nuclei of the protoplasmic sheath. He concludes that the suppression of physiological properties—or, in other words, the mortification of the axis-cylinder—does not precede, but follows, the anatomical alterations. Consequently, this specific necrosis cannot be the cause of the alterations.

This argument appears irrefutable. But it is possible that mortification may begin in the peripheral segment of the cylinder-axis immediately after section, without causing the suppression of excitability or of conductibility.

Functional death gradually takes place in the peripheral extremity immediately after section, as is observed in large animals; organic death progresses simultaneously, and immediately exercises its influence upon the surrounding protoplasm.

This opinion, in conjunction with the important facts discovered by Augustus Waller, led M. Arloing to conclude that the trophic centres described by this author are simply the generating centres of the fundamental portion of the nerve-fibres. Consequently a fibre will present the phenomenon of degeneration when separated from the cell from which it proceeds, or when this cell loses its own properties.

The greater number of modern embryologists concur in the opinion that the rachidian ganglion proceeds from the medullary tube, but they are unable to explain the manner in which the posterior roots develop. Some believe, with Balfour, Hensen, Marshall, Kölliker, Bedot, that these roots proceed from the same substance which supplies the ganglion; others believe, with His, that they are formed by very thin fibres which proceed from the ganglion to the spinal marrow, or from the spinal marrow to the ganglion, according to Sagemehl. The opinion of His is the more probable.

The observations made by Waller upon the results consequent upon section of the posterior roots have proved that the centre of emission of their fibres resides in the rachidian ganglion. Thus, the cells of this ganglion are at the same time the emitting centre (*centre émissif*) of the fibres of the posterior roots, of the peripheral fibres, and of the mixed nerves.

This fact is true in the case of fishes as well as in mammals.

The Deiter nerve-process in the ganglionic cells of a dog is bipolar. The constitution of this process may be explained by bending the opposite poles of the cells of a fish towards each other. When this bundle of axis-cylinder filaments has extended to a certain distance it divides into two: one bundle proceeds towards the spinal marrow, the other towards the periphery. At the point where this division takes place an annular constriction occurs. This phenomenon invariably takes place at

the bifurcation of the pre-terminal nerve-fibres. The connecting fibre which unites the cells of the ganglion with the cells of the medullary tube is almost exclusively formed by the ganglionic cell.

When the spinal marrow is compressed in its continuity, degeneration progresses upward in the posterior cords and downward in the anterior cords. Modern anatomo-pathologists, or rather pathologists, deduce the following law from these facts: The columns of the spinal marrow degenerate according to the direction of the nerve-transmission.

It is more reasonable to ascribe these phenomena to the law of degeneration of radicular fibres, and say that degeneration in the fibres of the posterior cords proceeds upward, because their emitting centres (*centre émissif*) are situated in the spinal ganglia or the medulla, while the fibres of the posterior cords have their emitting centre in the cephalic portion of the cord. The cells which, in some species, are dispersed in the interior of the posterior cornua are simply supplementary cells (*cellules de relais*), placed on the track of the nerve-fibres which unite the periphery with the sensitive centres, or with the centres of ideation of the cerebral cortex. Analogous parts are also found on the track of the motor system. Waller's experiments show that the trophic centre, or emitting centre (*centre émissif*), of the motor roots is enclosed in the cord. The anterior spinal ganglia (if such an expression may be used) remain confounded with the medullary tube, though in some cases they are removed to a certain distance. Such is probably the signification of the ganglion placed on the passage of the hypoglossal nerve (Meyer, Vulpian, Toussaint). Among the cells of the anterior cornua there are some which bear the same relation to the anterior roots as the cells of the spinal ganglion bear to the posterior roots. These cells are produced without and within, and are connected on this side by the anterior roots and by their mediation with the psycho-motor cells, or with the supplementary cells (*cellules de relais*), interposed between these last and the trophic cells. The spinal marrow is not possessed of motor spontaneity. But it possesses reflex power: therefore it must be admitted that the supplementary cells are connected with the posterior roots. These relations remain to be determined.

The most interesting deduction drawn from these considerations is that concerning the precise function exercised by the cells of the anterior cornua. None of these cells are auto-motory. They receive their impulse from the cerebral cells. If this impulse ceases to proceed from the brain on account of the cortex being destroyed, or if it is prevented from reaching the medulla cells by the existence of a solution of continuity in the connective tissues, paralysis will exist simultaneously with sclerosis of the cords of the spinal marrow, while the anterior cornua and roots are intact.

If the suppression of motor impulse lasts longer, the degeneration which occurs in the fibres of the anterior cords reaches the supplementary cells (*cellules de relais*), then the emitting cells (*cellules émissives*), and, finally, the roots themselves. This probably happened in the case of M. Charcot's and M. Brissaud's observations, where muscular atrophy was always preceded by organic alteration of the cells of the anterior cornua.

If paralysis follow a medullary lesion, the alteration of the anterior cornua must necessarily follow. But it is possible that in a medulla lesion one group of the cells of the anterior cornua may be degenerated whilst the other is intact. In other words, a case may occur in which the trophic cells of the anterior roots are alone destroyed; in another case the supplementary cells (*cellules de relais*) may be the only ones deteriorated.

M. Arloing concluded his communication by remarking that all these facts corroborate the law of degeneration established by Waller.

NOTES FROM SPECIAL CORRESPONDENTS.

LONDON.

THE season of medical activity as displayed in societies and medical schools is over for the academic year 1886–7, and already the centre of interest is shifting to Dublin, where we are promised a most successful meeting of the British Medical Association. Dr. Banks, Regius Professor of Physics in the University of Dublin, presides over the meeting, and his presidential address consists chiefly of an historical sketch of the growth of the Irish school of medicine. He shows that in 1618 medicine became an integral part of the teaching of the

then young University, which, like Harvard, had been organized by Cambridge graduates. The candidate for a degree in medicine at that date was required to have studied for seven years after taking the M.A. degree, and at the end was required to engage in a public disputation; he was, moreover, required to afford proof that he had cured four cases of different diseases,—a very unusual and it would seem impracticable regulation, seeing that the degree to be obtained at this examination was his license to practise. The College of Physicians took origin in 1626, when Charles I. addressed a letter to Viscount Falkland "creating" a college after the pattern of the College of Physicians in London. One of the original Fellows of this college was Sir William Petty, an erratic genius, who, after filling simultaneously the apparently incongruous chairs of Anatomy and Music in Oxford, passed over to Dublin, became Physician to the Parliamentary army, then Clerk of the Council and Secretary to Oliver Cromwell, and finally, growing immensely wealthy, founded the family of which the Marquis of Lansdowne (Governor-General of Canada) is now the head. The College of Physicians got its present cumbrous title of the "King's and Queen's College of Physicans of Ireland" in 1699, when a new charter was granted to it by William and Mary. Sir Patrick Dun, who bequeathed money which was used for founding the hospital which bears his name, had been William's physician, and was the first president of the college. Dublin has altogether three hospitals founded by the munificence of physicians, the other two being the Steevens and the Rotundo Lying-In Hospital. Of the eminent men who belonged to the Dublin school of medicine in the earlier part of the present century it is hardly necessary here to speak at length. Dr. Banks mentions especially Dr. Cheyne, Dr. John Crampton, Sir Philip Crampton, Sir Henry Marsh, Dr. Graves, Dr. Stokes, and Sir Dominick Corrigan. The latest addition to Irish universities—the Royal University—is also one of the most vigorous, the total number of persons presenting themselves at the various examinations last year having been two thousand nine hundred and thirty-three. It is, I believe, the only university, besides the London University, in the United Kingdom which gives degrees to women. Last year the degree of B.A. was conferred on nine women, and the degree of M.A. on one, an event said to be unprecedented in university annals.

The address in medicine by Professor Gairdner also is an historical essay. He addresses himself to answer the question, asked in somewhat scornful wise by Sir William Hamilton, "Has the *practice* of medicine (that is, the art as distinguished from the science) made a single step since Hippocrates?" The general result at which Professor Gairdner arrives is that whatever hesitation might have been felt by an impartial observer in 1832, when the great Edinburgh Professor of Logic and Metaphysics propounded his mocking question, none can fairly be felt now. The permanent gains which he believes have been made are (1) the increased power of managing disease afforded by the lessons learned from preventive medicine; (2) the abolition of routine blood-letting; (3) the treatment of fevers *lacte non vino*, to quote the words of the Public Orator when an honorary degree was recently conferred on Professor Gairdner by the University of Dublin; and, finally and inclusively, an increased stability of the medical art, a more secure position in connection with demonstrable or demonstrated facts, so that it would be no longer possible for any man, coming forward with a new theory not based upon the careful study of facts, to make such a revolution in medical practice as John Brown, of Edinburgh, achieved a century ago, and "such as has been over and over again witnessed in the history of medicine almost from the days of Hippocrates."

Dr. Gasquet's address as president of the Section of Psychology is a plea for a more systematic study of the mental and moral as distinguished from the purely bodily phenomena of insanity. In the causation, he thought, greater attention should be given to the influence of the various passions,—jealousy, remorse, anxiety, grief,—which act, indeed, only by and through the nervous system, but in their nature and origin are mental rather than cerebral. While with regard to symptoms he contends that, speaking generally, it might be said that the bodily condition supplies the general direction which the insanity takes, while the details by which each individual seeks to account for his altered feelings are derived from his past mental experiences. He refers as an unsettled point to the question whether all the mental faculties are alike liable to perversion, or whether any laws of thought or processes of mind remain always normal so long as they are manifested at all. In conclusion, he asks whether the psychological side in the treatment of the insane has not been unduly neglected,—neglected, that is to say, not by individual physicians, but as a systematic method, the principles upon which such a system of treatment must rest never having been laid down.

In the Section of Medicine Dr. William Moore's address is very short, and is chiefly concerned with a comparison of the existing knowledge of the pathology of fever—by pathology is not to be understood morbid anatomy, but the "pathonomy" of Dr. Moxon—with that of thirty or forty years ago. He lamented that while in diagnosis and morbid anatomy precision was attainable, in prognosis and treatment we had not advanced beyond the domain of probability.

Sir George Porter in addressing the Section of Surgery is very brief, confining his remarks to a welcome; in the Sub-Section of Laryngology Dr. McNeill Whistler is not much more lengthy, but he suggests the formation of a Laryngological Association, which would afford better opportunities for discussing and sifting theories than laryngologists in this country at present possess.

The report of the Committee appointed by the Local Government Board to inquire into M. Pasteur's treatment of hydrophobia is very favorable to him. The Chairman of the Committee was Sir James Paget, and the other members were Dr. Lauder Brunton, Dr. George Fleming (Principal Veterinary Surgeon of the Army), Sir Joseph Lister, Dr. Richard Quain, Sir Henry Roscoe, M.P., and Professor Burdon Sanderson. Many experiments were conducted for the Committee by the Secretary, Professor Victor Horsley, F.R.S.

The report, first of all, refers to the preventive inoculation of dogs; after summing up the evidence it continues:

"It may, hence, be deemed certain that M. Pasteur has discovered a method of protection from rabies comparable with that which vaccination affords against infection from smallpox. It would be difficult to overestimate the importance of the discovery, whether for its practical utility or for its application in general pathology. It shows a new method of inoculation, or, as M. Pasteur sometimes calls it, of vaccination, the like of which it may become possible to employ for protection of both men and domestic animals against others of the most intense kinds of virus. The duration of the immunity from rabies which is conferred by inoculation is not yet determined, but during the two years that have passed since it was first proved there have been no indications of its being limited."

The contention that his system may be applied to the prevention of the development of hydrophobia in an individual already bitten by a rabid animal is, of course, a very different proposition. To it the Committee especially directed its attention: it is pointed out that the question cannot be answered by a mere numerical comparison of the cases treated and untreated, owing to (1) the impossibility of ascertaining with certainty in all cases whether the animals were really rabid; (2) the varying danger of bites inflicted through clothes or on the naked flesh, of bites treated or untreated by local cauterization, of bites which bleed freely or not; (3) the varying virulence of the animal inflicting the bites, the bites of rabid wolves and (probably) of rabid cats being more dangerous than those of rabid dogs. Certain members of the Commission who went to Paris carefully investigated a series of ninety cases taken consecutively from those appearing earliest in M. Pasteur's register. They visited these patients in their homes and collected evidence on the spot: the result was that of the ninety cases twenty-four were bitten on naked parts by undoubtedly rabid dogs, and the wounds were not cauterized nor treated in any way likely to have prevented the action of the virus; in thirty-five cases the dogs were rabid, but the bites were inflicted through clothes; and in thirty-one there was no clear evidence that the dog was rabid. None of the ninety persons died of the disease, whereas the Commission estimate that eight would have died if untreated by M. Pasteur. He, however, has inoculated many persons with regard to whom there was no evidence that they had been bitten by rabid animals, but who feared that they had: consequently in calculating the general result of his method it is necessary to take a very low percentage of mortality. The lowest rate ever assigned is, according to the report, five per cent. of the persons bitten. Between October, 1885, and December, 1886, M. Pasteur inoculated two thousand six hundred and eighty-two persons: of this number thirty-three (or, according to the anti-Pasteurians, forty) died of hydrophobia: five per cent. would have given one hundred and thirty. In two hundred and thirty-three cases it was proved, either by inoculation from their spinal cords or by the occurrence of rabies in other animals bitten, that the biter was rabid; only four of these persons died; the Commission estimate that without M. Pasteur's treatment forty would have died. The conclusion on this head is given in the following terms:

"From the evidence of all these facts, we think it certain that the inoculations practised by M. Pasteur on persons bitten by rabid animals have prevented the occurrence of hydrophobia in a large proportion of those who, if they had not been so inoculated, would have died of that disease. And we believe that the value of his discovery will be found much greater than can be estimated by its present utility, for it shows that it may become possible to avert by inoculation, even after infection, other diseases besides hydrophobia. Some have, indeed, thought it possible to avert smallpox by vaccinating those very recently exposed to its infection; but the evidence of this is, at the best, inconclusive; and M. Pasteur's may justly be deemed the first proved method of overtaking and suppressing by inoculation a process of specific infection. His researches have also added very largely to the knowledge of the pathology of hydrophobia, and have supplied what is of the highest practical value,—namely, a sure means of determining whether an animal which has died under suspicion of rabies were really affected with that disease or not."

The report next passes to the question

whether the treatment is itself free from danger. It will be remembered that M. Pasteur has made use of three different methods: the ordinary method employed at first, and still used in all cases but those considered especially dangerous; the "intensive method" (*méthode intensive*), first introduced when the patients bitten by wolves died in such large proportion; and the modified intensive method, used in dangerous cases since the fear has arisen that the intensive method may itself be dangerous. The three methods are shown in the following tables taken from the report:

TABLE I.—*Early or Ordinary Method.*

Days of Inoculation.	1st.	2d.	3d.	4th.	5th.	6th.	7th.	8th.	9th.	10th.
Days during which the spinal cord had been dried...	14	13	12	11	10	9	8	7	6	5

TABLE II.—*Intensive Method.*

Days of Inoculation.	1st.	2d.	3d.	4th.	5th.	6th.	7th.	8th	9th.	10th.	11th.
Days' drying of the cords.....	14, 13, 12	11, 10, 9	8, 7	6, 5	4, 3	2	1	6, 5	4, 3	2	1

TABLE III.—*Modified Intensive Method.*

Days of Inoculation.	1st.	2d.	3d.	4th.	5th.	6th.	7th.	8th.	9th.	10th.	11th.	12th.	13th.	14th.	15th.
Days' drying of the cords...	14, 13	12, 11	11, 10	10, 10	9, 9	9	8	8	8	7	7	7	6	6	5

The Committee state that "by the first or ordinary method there is no evidence or probability that any one has been in danger of dying, or has in any degree suffered in health even for any short time. But after the intensive method, deaths have occurred under conditions which have suggested that they were due to the inoculations rather than to the infection from the rabid animal."

The symptoms bore a striking resemblance to those of paralytic rabies (the form usually seen in rabbits and occasionally in dogs), and in one case, that of Goffi, an attendant at the Bronn Institution, bitten by a rabid cat, it was shown by inoculations made with his spinal cord that his death was due to rabies: whether the rabies of the cat or the rabies of the intensive inoculations cannot be proved, though Mr. Horsley thinks, from a comparison of the dates, that it could not be the latter. Goffi was bitten on September 4, M. Pasteur's treatment was commenced on September 5; he was taken ill on October 18, and died on October 20. The symptoms were those of acute ascending paralysis (Landry's paralysis), and it is suggested that some at least of the cases described under this name may have been cases of the paralytic form of hydrophobia, which is stated (though no authority is given) to have been observed in men bitten by rabid animals and not inoculated. Whether the intensive method was responsible for some of the deaths is left undecided, as it was thought unnecessary to pursue further a very complicated question which has ceased to have any practical interest owing to M. Pasteur having now adopted a modified course. The general conclusion of the Committee is that hydrophobia and rabies might be stamped out by the rigid enforcement of adequate police regulations with regard to dogs. The average annual number of deaths from hydrophobia in England for the decade ending 1885 is forty-three: if this be taken to represent five per cent. of the persons bitten, it would seem that M. Pasteur's treatment would be required by eight hundred and sixty persons every year in England alone.

An interesting discussion of ophthalmoplegia was raised by a paper read by Mr. Jonathan Hutchinson, Jr., at the Ophthalmological Society. The most important point brought out was that there were two, if not three, different classes of cases of ophthalmoplegia externa, and that the prognosis probably differed in each. The diagnosis therefore becomes of practical importance. There is a type of the disease in which it is symmetrical from the first, gradually progressing to complete paralysis of all the muscles; this is very intractable, and is probably due to cerebral lesion. In another type the disease was not symmetrical, came on quickly, and generally got well. The paper read by Mr. Hutchinson, Jr., was an example of the second class; the right eye only was affected; the patient died of cellulitis occurring around a syphilitic ulcer of the leg. The ophthalmoplegia was found to be due to neuritis sec-

ondary to chronic inflammation about the right cavernous sinus, which had also produced obliteration of the sinus, partial obstruction of the carotid artery, and adhesion of the apex of the temporo-sphenoidal lobe to the dura mater. In two other very similar cases of ophthalmoplegia interna and externa recovery took place under iodide of potassium, and there was very strong reason for believing that in all the cases the inflammation was of syphilitic origin. It was pointed out that the occurrence of protrusion of the affected eye and congestion of the lids present in these cases was due to the involvement of the cavernous sinus, and might be of great use in making a diagnosis. Dr. Necles, during the discussion, mentioned a case which must be very rare: double ophthalmoplegia externa and interna (coming on gradually, first affecting one eye and then the other) due to tubercular meningitis.

At a previous meeting an excellent discussion took place on toxic amblyopia. The general opinion was in accord with that expressed by Mr. Nettleship in opening the discussion: namely, that tobacco is a more powerful agent than alcohol, and is capable of producing amblyopia which is characterized by a central scotoma without the aid of alcohol in any form. Since the amblyopia comes on in many cases at a time when no alteration in the quantity or quality of the tobacco used is made, there must be some other determining element, and this is to be looked for either in a mental shock or perhaps in failing vitality due to increasing age. Tobacco-amblyopia is seldom seen before forty years of age, and is certainly more common in persons who smoke strong tobacco and drink much alcohol. If the sufferer will give up tobacco the vision rapidly improves and the prognosis is on the whole good, though relapses may occur if the habit of smoking is resumed. Some ophthalmologists prescribe strychnine, and others iodide of potassium; but it is at least doubtful whether either drug has anything to do with the recovery.

Mr. Cross, of Bristol, related to this Society two cases in which he had eviscerated the eye and introduced an artificial vitreous into the sclerotic in the manner recommended by Dr. Mules, of Manchester. In both cases the operation was done for penetrating wound, in both the wound was found after some days to have gaped, and in both the remaining eye became affected with sympathetic ophthalmitis seventeen and twenty-one days respectively after evisceration. The cases were considered to be analogous to cases of sympathetic ophthalmitis occurring after and in spite of enucleation, but not caused by the operation. The danger of such a fistulous track as was caused by the gaping of the sclerotic junction over the globe was, however, pointed out. Mr. Cross thought that such a septic fistula might result either from imperfect healing or from wearing away of the conjunctiva between the artificial vitreous and the artificial eye. Dr. Miles said that these two cases were the first recorded instances after his operation. The general opinion was that Mr. Cross had rightly described both his cases as examples of sympathetic ophthalmitis; and in this connection the existence of a fistula leading from the conjunctival sac to the sclerotic cavity is worthy of note, though Mr. Cross was inclined to attach far more importance to a probable tendency to sympathetic ophthalmitis existent before the operation.

The accounts of the improvement which has taken place in the Crown-Prince of Germany are most glowing. Dr. Morell Mackenzie has got away the whole of the growth, leaving, however, a broad base, and the prince's voice has greatly improved.

Mr. W. S. Savory, F.R.S., Senior Surgeon to St. Bartholomew's Hospital, has been re-elected President of the Royal College of Surgeons of England, and now enters upon his third term of the office. This is a departure from the usual custom, which has been to choose a new President every year. It is probably, in part at least, dictated by a desire to leave the negotiations in progress for obtaining a new charter and the right to grant degrees in medicine in the same hands. The proposed charter creating a "Senate of Physicians and Surgeons" has been published. The Senate would consist of the President and twenty-three members of the Council of the College of Surgeons, and the President and twenty-three Fellows (elected by the Comitia) of the College of Physicians. The general principle of the scheme appears to be universally approved. The omission of the teachers as such can be defended on the ground that the Senate, constituted as above stated, would probably consist entirely of men who were engaged in teaching or were in the position of Emeritus Professors. Whether the graduates of a university ought or ought not to have some recognized share in the constitution of the governing body has always been a matter of dispute from the earliest days of universities. It is the custom in England to admit this right; but this custom has been the source of many conflicts at Oxford and Cambridge, even in recent years. Its omission, however, from the present scheme is not a popular move, using that phrase in the political sense.

Mention was made in an earlier letter of the new regulations for the Croonian lectures at the Royal College of Physicians. The augmented income of the Trust Fund permits the College to give the Lecturer one hundred pounds as his honorarium, and a similar sum will be placed at his disposal to defray the cost of experiments and generally for making preparations for his lectures. Dr. Donald Macalister, who is a Fellow of St. John's Col-

lege, Cambridge, and is Secretary to the Medical Board in Cambridge, will be the first lecturer under the new regulations. His lectures, given early this year at the College of Physicians, on "Fever," were highly appreciated, and there is every reason to hope that he will be able to establish a good precedent. Dr. W. H. Dickinson will be the Lumleian Lecturer. He has chosen for his subject "The Tongue considered with Reference to Constitutional and Organic Diseases,"—*i.e.*, considered symptomatically.

The two Colleges of Physicians and Surgeons in London are the owners of some spare ground adjoining the new Examination Hall on the Thames Embankment. It has been determined by formal resolution to make use of this site for the erection of a building for "the investigation and exposition of such branches of science connected with medicine and surgery as the two colleges may from time to time determine." This is understood to mean a lecture-theatre and laboratories.

We are at present suffering from drought. There has been no general rain for three months, and the few showers which have fallen here and there have not made any appreciable difference; streams and ponds which are usually full throughout the year are dried up, and the stock of water for drinking in many localities is seriously diminished. In Swansea indeed there is a "water-famine," and Manchester is threatened with a like misfortune. So prolonged a drought is very uncommon in this rainy isle, and town and country districts are alike as unprepared for it as is London for a heavy snow-storm in winter.

DAWSON WILLIAMS.

PROCEEDINGS OF SOCIETIES.

AMERICAN CLIMATOLOGICAL ASSOCIATION.

(Continued from page 741.)

THE next paper read was by Dr. B. F. Westbrook, of Brooklyn, on

THE LOCAL TREATMENT OF DISEASES OF THE RESPIRATORY ORGANS.

The methods of treatment which had been employed were the direct introduction of coarse sprays, the use of the Evans inhaler, and the use of the pneumatic cabinet. In cases of chronic bronchitis where the cough was severe, a spray of a solution of carbolic acid, fluid extract of hyoscyamus, or other sedative remedies, was employed. Where there is copious secretion, astringents are called for, and of these tannic acid, iron salts, and fluid extract of pinus canadensis had been employed. The pneumatic cabinet had been used with marked success in the treatment of chronic bronchitis. The patient is confined in the cabinet under a diminished pressure, the sitting lasting from ten to fifteen minutes. This may be combined with the inhalation of the spray. If there is much emphysema the cabinet is not indicated. In using the cabinet in the treatment of chronic interstitial pneumonia and bronchiectasis there is danger, if the pressure is great, of producing emphysema of those portions of the lung still accessible to the air. The pressure should not exceed one-half an inch of mercury.

In the treatment of phthisis the best results are obtained in the early stages of the disease, or where the disease, although further advanced, is limited to a small portion of the lung. The use of sprays is beneficial only in so far as we desire to treat the coexistent bronchitis or cavities connected with bronchi of the second or third order. In incipient phthisis with very little bronchial catarrh, local treatment is probably of little service. These cases are best treated with compressed air. In a large proportion of the cases we may hope to render the disease latent. The expansion of the lung favors the expectoration of the contents of the smaller tubes and modifies the intra-thoracic circulation. The sittings should be frequent: every day, or every second day. Ten minutes is usually sufficiently long for the patient to remain in the cabinet. The pressure should gradually be increased up to one-half or three-fourths of an inch. If used cautiously, this is the best method for the local treatment of incipient phthisis. With the Evans inhaler his results had also been satisfactory.

In the treatment of advanced cases of phthisis the first effort must be to cure or diminish the bronchitis. The pneumatic treatment then comes into play. This gives better expansion, improves the circulation, and alters the action of the trophic nerves. In all cases internal medication has been combined with the local treatment. The more acute the disease the higher the fever, and the more sudden the onset the less can we expect to accomplish by treatment. In no single case diagnosticated as acute phthisis did treatment have the slightest effect.

Dr. A. Y. P. Garnett, of Washington, D.C., read the first paper of the second morning session, entitled "Observations upon the Sanitary Advantages of Tidewater Virginia, including Virginia Beach, as a Winter Health-Resort."

The next paper was by A. L. Loomis, M.D., of New York City, on

EVERGREEN FOREST AS A THERAPEUTIC AGENT IN PULMONARY PHTHISIS.

It has long been known that similar climates, as determined by geographical and meteorological conditions, have different therapeutic effects. That there is some rela-

tion between the development of organisms and atmospheric conditions is becoming more and more apparent. We know that cold and high altitudes render the air aseptic, but the degree of cold and the height required are so great that clinically it is not possible to derive much advantage from this fact. The effect of a purely aseptic air upon ulcerative processes is not so great as the effect of an atmosphere which is aseptic on account of the presence of antiseptic agents. The belief in the good effect of pine forests in cases of phthisis is quite unanimous, and the author thought that the clinical evidence in favor of their beneficial influence in these cases was also unquestioned. The atmosphere in such regions is not only aseptic, but also antiseptic. Such an atmosphere contains considerable turpentine vapor, and we should therefore expect it to contain a certain amount of peroxide of hydrogen. In the speaker's opinion, the majority of cases of phthisis die not directly from the lesions in the lung, but from the secondary septicæmia and pyæmia which is set up. It is impossible to apply to the ulcerations within the lung the antiseptic washing and dressing that is employed in external lesions; but if an antiseptic atmosphere can be obtained we may hope to counteract the secondary poisoning. Such an atmosphere will not destroy the bacilli, but it will accomplish much in the way of arresting the suppurative process. It was the opinion of the speaker that the atmosphere in the region of evergreen forests acts in a manner similar to the antiseptic agents which are successfully used to arrest suppurative processes in other portions of the body. He thought that in all probability the active agent was the peroxide of hydrogen resulting from the oxidation of the turpentine-vapor. While it is not possible for every one suffering with pulmonary phthisis to obtain an antiseptic atmosphere, yet it is possible to render the air of any particular locality antiseptic. The evergreen forests should be preserved, and evergreen trees should be planted in the neighborhood of our homes.

A paper entitled "The Climate of the Sub-Peninsula, Pinellas, Florida," was read by Dr. W. C. Van Bibber, of Baltimore.

ENVIRONMENT IN ITS RELATION TO THE PROGRESS OF BACTERIAL INVASION OF TUBERCULOSIS

was the subject of a communication read by Dr. E. L. Trudeau, of Saranac Lake.

Environment evidently has an important bearing in reference to bacterial invasion. The author proposed to himself the following questions: 1. What results ensue when bacillar invasion and unhygienic conditions are made to coexist? 2. Are unhygienic surroundings sufficient to cause phthisis when precautions are taken to exclude the bacillus? 3. Is bacterial infection always productive of tuberculosis when the animal is placed under the most favorable hygienic conditions? In order to answer these questions the following experiments were performed. Fifteen healthy rabbits were taken and divided into three sets of five each. The first experiment consisted in taking five of the rabbits, inoculating each with a pure culture of the tubercle-bacillus, and subjecting them to overcrowding in a dark cellar, with poor and insufficient food and other unhygienic conditions. In the second experiment five rabbits were placed in a box and lowered into a pit dug in the ground, the mouth of the pit covered with earth with the exception of a trap-door for the introduction of food, which consisted of one small potato for each animal per day. So damp was the air that the box in which the animals were confined was constantly wet. The third set of animals were inoculated with the tubercle-bacillus and turned loose on a small island, where they had abundant sunlight, fresh air, and exercise. They were daily supplied with wholesome food.

The results of these experiments were that four of the first five rabbits died in three months, and extensive tuberculosis was found. The fifth animal was killed at the end of five months, and the same condition found. The second set of five rabbits were all living at the end of four months. They seemed to be as active as at the time the experiment began. They were then killed, and careful examination revealed nothing abnormal. One of the third series of rabbits died at the end of one month, and on examination there was enlargement of the cervical and bronchial glands, and tubercles in the spleen. The remaining rabbits continued in apparently good health, and were killed at the end of four months. They were loaded with adipose tissue, the flesh was firm and red, all the organs were normal, and even the seat of the punctures could not be made out. These experiments confirm the view that the production of tuberculosis is a most complex process. Although the environment may bear but the relation of a predisposing cause to the microbe invasion, it is nevertheless a most potent factor in determining the future and the final results of the disease, and, while we may not underestimate the pathogenic properties of the bacillus, the effect of environment upon the vitality is a factor which must not be ignored.

At the afternoon session the first paper was read by Dr. Walter Platt, of Baltimore, "On the Climate of St. Moritz, Upper Engadine, Switzerland."

Dr. A. C. Peale, of the United States Geological Survey, Washington, presented "A Classification of American Mineral Waters."

"St. Augustine as a Winter Health-Resort" was the title of a paper by Dr. F. F. Smith, of St. Augustine.

He described the geographical and climatic conditions existing in St. Augustine. An abundance of pure water is obtained from sixty artesian wells; this water is charged with sulphuretted hydrogen. Drinking-water is obtained by means of cisterns. A complete system of sewers is now being introduced; these will be flushed by the waste water from the artesian wells. The average temperature during the winter months of the past ten years has been as follows: November, 63°; December, 57°; January, 55°; February, 58°; March, 61°; April, 67°. The average number of rainy days during the winter months for the past ten years has been thirty-three, but on nineteen of these occasions the rainfall was at night, so that there were really only fourteen rainy days.

The following papers were read by title:

"An Invalid's Day in Colorado Springs," by Dr. S. E. Solly, Colorado Springs.

"The Climate of Southern California," by Dr. H. S. Orme, Los Angeles, California.

"Pass Christian, Mississippi, as a Health-Resort," by Dr. Charles Le Roux, Pass Christian.

The report of the Committee on the Congress of American Physicians and Surgeons was received and adopted. Dr. A. L. Loomis, of New York (with Dr. F. Donaldson, Sr., of Baltimore, as alternate), was appointed as the representative of the Association to the Committee on the Congress.

The following were elected to membership:

Drs. A. L. Gihon, U.S.N.; W. P. McDougal, San José; A. C. Peale, U.S. Geological Survey; E. Wilds Linn, Los Angeles; F. F. Smith, St. Augustine; F. P. Henry, J. J. Levick, and Thomas J. Mays, Philadelphia; Thomas C. Leatmer, J. Carey Thomas, and Walter Platt, of Baltimore; S. E. Solly, Colorado; S. W. Langmaid, Boston; S. E. Morgan, Washington; S. H. Chapman, New Haven; and S. A. Fisk, Denver.

Officers for the ensuing year—

President.—Dr. A. L. Loomis, New York.

Vice-Presidents.—Drs. A. Y. P. Garnett, Washington, and James T. Whittaker, Cincinnati.

Secretary and Treasurer.—Dr. James B. Walker, Philadelphia.

Council.—Drs. E. T. Bruen, Philadelphia; J. H. Tyndale, New York; F. H. Bosworth, New York; F. H. Shattuck, Boston; and R. G. Curtin, Philadelphia.

The Association then adjourned.

THE ASSOCIATION OF AMERICAN PHYSICIANS.

(Continued from page 744.)

DISCUSSION ON ANTIPYRETICS.

DR. I. E. ATKINSON, of Baltimore: So far as the temperature-reducing power of these agents is concerned there can be no question, but, as has been said, we are coming more and more to realize that elevation of temperature is far from being all there is in pyrexia. As regards the relative merits of thalline, antipyrine, and antifebrine, I think that the tendency to chilling after the use of thalline is decidedly greater than after the use of antipyrine, while the latter is more apt to produce nausea and vomiting. I am disposed to disagree with the statement that the use of these drugs can take the place of the external application of cold water. My experience with the latter measure has been limited. It has recently been reported that one observer abroad has treated two hundred cases in private practice by the use of baths with a mortality of nothing; in army hospitals he has had a mortality of five per cent., and in ordinary hospital practice a mortality of less than eight per cent. Although with antipyretics we can reduce the temperature at pleasure, yet the duration of the case is not lessened, and in some cases it has been thought to have been prolonged.

Dr. H. C. Wood, of Philadelphia: We must not look upon the use of cold water as acting merely by the abstraction of heat. I am convinced that the action is more than this. It probably exerts some reflex influence through the superficial nerves.

Dr. George L. Peabody, of New York: A certain proportion of cases which do not bear the cold bath will bear the use of antipyretic drugs, while, on the other hand, the bath may be used in a certain number of cases in which antipyretics cannot be applied. From clinical experience he was convinced of the truth of the statement of Dr. Wood, that the cold bath accomplishes more than the simple reduction of temperature. Its soothing effect upon the nervous system is greater than that accomplished by the reduction of temperature by antipyretic drugs. In many instances the course of the disease is favorably modified by the use of the cold bath.

Another important matter is that since the introduction of these methods of treating fever by antipyretics the number of relapses seem to be greater and more fatal.

He understood the lecturer to say that antipyrine acted solely by diminishing heat-production, and that it did not increase heat-dissipation. He must differ from him on that point. It seems that the increase of heat-irradiation from the surface is very great, not only where it produces sweating, but also where it does not.

Dr. W. W. Welch, of Baltimore, said that he should like much to hear a discussion of the question, How far is the rise in temperature an important element in fever, and an element which calls for interference on the part of the physician? There is comparatively little evidence that the grave symptoms of fever are due simply to the elevation of temperature. There is no doubt that temper-

atures of 110° to 113° produce serious symptoms, but whether or not ordinary temperatures of 105° to 107° exert any serious action on the body is a question which is certainly unsettled. It has been shown that rabbits can be kept in a box with a continuous rectal temperature of 107° for at least two weeks, provided the precaution is taken to keep the box well ventilated and the animals supplied with moist food. Patients may have a perfectly clear brain, and no grave symptoms, with a temperature of 106° or 107°. On the other hand, there are severe and fatal cases of typhoid fever in which the temperature has never registered a great height. While in most cases there is a certain proportion between the height of the temperature and the severity of the disease, yet there are certain cases where this proportion does not exist.

Dr. William Pepper, of Philadelphia: From his experience he had been disposed to think that antipyrine and antifebrine in their antipyretic effect were superior to thalline; as between the two former he had not noticed any marked difference. He had used both largely in a variety of cases, and had not seen any of the dangerous symptoms which have been mentioned by some writers. The action of these drugs seems to be purely through the nervous system, with no effect upon the circulation, the respiration, or upon the secretions save that of the skin. Some of his observations bore upon the question of the relative value of the external use of cold water and the internal use of antipyretics. In the sudden acute pneumonias of children with a temperature of 106° or 107°, with initial convulsions, where the prompt and repeated use of cold baths has been without result, full doses of either of these antipyretics have produced a remarkably successful effect. In a recent case in a child with double croupous pneumonia, involving two-thirds of the left lung and one-third of the right lung, with a temperature in the rectum of 107° and with repeated convulsions, cold baths failed to relieve the symptoms, although repeated at intervals of three hours. Antipyrine in repeated doses controlled the pyrexia at the beginning and on several occasions during the course of the disease, and after a severe struggle the child recovered. As to the ability of these agents to replace cold baths under all circumstances, the evidence is not adequate. In the sudden hyperpyrexia occurring in the course of rheumatism, he was not prepared to accept the view that these drugs are capable of replacing the cold bath. In these cases we have direct evidence that the high temperature is the direct cause of the symptoms, at least of the severe nervous symptoms. He was not one of those who consider high temperature in itself a dangerous symptom. There is no proof that high temperature—provided that it has not induced secondary changes—should be regarded other than as one symptom of the disease. Many of his patients with typhoid fever, with a temperature of from 103° to 105°, have done perfectly well without any measures directed to the reduction of the fever. We, however, meet with cases in which these temperatures are attended with certain symptoms for which there is apparently no other cause. In such cases we must consider that the hyperpyrexia calls for treatment. He had noticed the effect to which attention has been called,—that is, the deep and tranquil sleep which follows the administration of these antipyretics.

Dr. George B. Shattuck, of Boston, had used both antipyrine and antifebrine largely, and it seemed to him that antifebrine offers all the advantages of antipyrine without its disadvantages. It has none of the disadvantages which belong to thalline. Three or four grains of antifebrine accomplish the same results as are produced by a larger dose of the other drugs. The disagreeable symptoms which some writers have referred to as following antipyrine are probably due to the fact that they follow the original recommendation and give two grammes of the drug. The same benefit may often be obtained from one gramme, and often from half this quantity. With reference to the point whether pyrexia is or is not a dangerous feature of the disease, we find clinically that where a patient has high fever and he is irritable, impatient, and uncomfortable, the administration of one of these antipyretics, or the external use of cold water, produces a tranquil and refreshing sleep, and he awakes in a condition much better fitted to continue the struggle with the disease.

Dr. J. C. Wilson, of Philadelphia, agreed with other speakers that antifebrine has many advantages over thalline, particularly in its cheapness and in the smallness of the dose. A recent observation which he had made is interesting as bearing on the question of heat-dissipation. In a case of typhoid fever under his care, antifebrine in five-grain doses was given, repeated whenever the temperature reached 104°. This caused copious sweating, with the usual reduction of temperature, amounting to three and a half or four degrees. On the last occasion one-ninety-sixth of a grain of sulphate of atropia was given with the antifebrine. No sweating occurred, and the temperature was reduced only one and one-half degrees.

Dr. James T. Whittaker, of Cincinnati, differed from those who accept the view that fever is a neurosis. There is no proof that the nerve-centres are distinctly irritated, that the agents which reduce fever act directly on the nervous centres. Is it not more probable that the antipyretic action is really an antimycotic action? We have some observations which go to show that the disease is caused by bacteria, or, if not directly by bacteria, by some of their products, the ptomaines.

Would it not be more rational to study the habits of these bacteria and address ourselves rather to the removal of the cause than to the counteracting of the effects?

Dr. H. M. Lyman, of Chicago: With regard to antifebrine and antipyrine my experience has been that of previous speakers, and my preference for the former drug is growing. Their great value proceeds not so much from their power to reduce temperature as from their general effect, especially upon the nervous system. I regard them as valuable adjuvants in the treatment of disease, largely from their hypnotic and tranquillizing effect upon the nervous system, to which allusion has already been made. In many instances, where in abrupt febrile affections relief has not been secured from antifebrine and antipyrine, this failure is frequently due to the presence of the rheumatic complication, and there salicylic acid will give the relief that we fail to get with the antipyretics.

Dr. John Guitéras: In some experience with these drugs in the treatment of the continued fevers of warm climates, the results had been rather negative, and had shown the advantage of stopping their use after they have been continued for a certain length of time. He had been called in consultation to cases where the drug had been continued for ten or fifteen days, each time that it was given producing a certain reduction of the temperature, but having no permanent benefit, and the patients have begun to improve as soon as the drug was stopped. It has seemed that when given continuously in this way they have an effect on the vaso-motor system. The pulse is weak and dicrotic, and he had considered it advisable to give digitalis. The effect of cold-water baths in these continued fevers of the South has seemed to him more beneficial. If continued for two or three days they often favorably modify the course of the disease.

Dr. George L. Peabody, of New York: With reference to the point suggested by Dr. Whittaker, there is no question in my mind that a considerable proportion of cases of typhoid fever can be aborted by antiseptic treatment of the intestinal ulcers with naphthaline or resorcine. For the past two years I have treated all cases coming under observation during the first ten days of the disease with a calomel purge (ten grains), followed by naphthaline in such doses that at least seventy or eighty grains were taken during the twenty-four hours. Under this treatment he had without doubt succeeded in aborting many cases in which the symptoms were quite pronounced. He had not succeeded in thus cutting short cases coming under observation at the end of the second week.

Dr. H. C. Wood, of Philadelphia, in regard to the dissipation of heat by sweating in his experiments, stated that in the dog there are but few sweat-glands, so that there could be no heat-dissipation from this cause. Sweating in man does undoubtedly cause a dissipation of heat. With reference to the possible influence of antipyrine on fever through some action on the bacteria causing the fever, he said that in the experiments to which he had referred no microbes were concerned in the production of the fever, which was induced by the pyrogenic principle of pepsin.

Dr. James Tyson, of Philadelphia: In a recent case of rheumatism the temperature suddenly went up to 105°, with alarming brain-symptoms. Antifebrine in five-grain doses failed to produce any effect. The patient was then put into a cold bath, and the temperature of the water gradually reduced to 72°. The discomfort experienced by the patient then prompted his removal from the bath. The thermometer in the rectum showed a reduction of only one-half of a degree, but within the course of half an hour the temperature fell three degrees. This was not considered as due to a natural defervescence, but must be attributed to the effect of the bath. The fall in temperature was followed by a disappearance of all the symptoms and the recovery of the patient. While he had never seen any serious results from the use of thalline and antipyrine, yet there have been symptoms which caused much alarm to the attendants. He had not seen such symptoms following the use of antifebrine.

Dr. R. Palmer Howard, of Montreal, wished to emphasize the fact that internal antipyretics and the cold bath are not equivalents; they are substitutes, and important auxiliaries to the physician. These measures relieve special symptoms, but whether or not they shorten the duration of the disease is a question not yet settled.

Another important point is with reference to relapse in typhoid fever. This is a subject which requires investigation. Every relapse, so called, is probably due to the absorption of fresh poison, and is really a fresh attack. It is really an initial attack. It runs a severe course, and often proves fatal.

(To be continued.)

NEW YORK PATHOLOGICAL SOCIETY.

STATED meeting, June 22, 1887, the Vice-President, W. P. NORTHRUP, M.D., in the chair.

GENERAL PERITONITIS.

Dr. MIDDLETON GOLDSMITH sent the specimens, which were presented by Dr. John C. Peters. Dr. King, of his place, was taken ill June 4, and sent for Dr. Caverly, who found him suffering with great pain in the right iliac region, without swelling or tympanites. The abdomen felt natural. Just before Dr.

Caverly's arrival the patient had taken an enema, without pain, but the first effort to pass anything from the bowels was attended by severe pain, and the second attempt by excruciating pain. Dr. Caverly found him with cold extremities, and the face had the ashen hue of death. Two-thirds of a grain of morphine were administered hypodermically, and hot-water bags were applied to the extremities. Dr. Goldsmith was then sent for, who, when he arrived, found the patient without pain; but he said he had been ailing with indefinite pain in the bowels and a good deal of pain in the right iliac region for three weeks; now there was nothing besides except general soreness over the abdomen. The first thought was that there had been some injury, perhaps rupture of the gut in the right groin. The patient died on the fourth day, and at the autopsy almost universal adhesions were found in the right side of the abdominal cavity; there was only about half a teacupful of serum in the cavity; the intestines had adhered to the liver and to other organs with which they came in contact. The gut was filled with water, and was felt to give way slightly under the grasp of the hand, as though there was a small vent; but the entire length of the intestine was examined, and no evidence of injury or an opening was found. All the other organs in the abdominal cavity were apparently in a healthy condition. There was no evidence of injury produced by the nozzle of the syringe with which the patient had injected the enema. Death had taken place from general peritonitis.

TRAUMATIC PERITONITIS—PNEUMONIA.

Dr. H. J. Boldt presented the lungs and heart removed from the body of a boy, aged 8 years, who on the 12th of June had received a violent blow upon the abdomen with the fist of another boy. He went home and to bed, and shortly afterwards began to suffer intense pain. He had considerable fever during the night, and complained more or less of pain. On the next day Dr. Boldt saw him, when he had a high temperature, extreme tenderness over the abdomen, especially marked in the ileo-cæcal region. Dr. Boldt diagnosticated traumatic peritonitis. In the course of two days, however, evidence of pneumonia developed, which progressed and involved the entire right lung, and subsequently the left lung to a slight extent. The consulting physician suggested aspiration of the right pleural cavity because he thought it contained fluid, but only twenty grammes of fluid were obtained. During the progress of the pneumonia the peritonitis was lost sight of. The patient died on the morning of the 22d of June, and the autopsy was made shortly before the specimens were presented. There was diffuse peritonitis, consolidation of the entire right lung, and some consolidation of the left lung. There was also extensive pericarditis.

PRIMARY EPITHELIOMA OF THE CONJUNCTIVA.

Dr. W. P. Northrup presented a specimen of primary epithelioma of the conjunctiva, occurring in a private patient 3 years and 2 months of age. The boy was first presented to him suffering apparently with a phlyctenula situated on the nasal margin of the cornea of the left eye. The case not progressing favorably, he asked Dr. Agnew to see it in consultation, who corroborated the diagnosis, and also expressed the opinion that it would probably prove to be one of those cases of phlyctenula in which there was delay in the process of repair, and which might leave a trifling amount of thickening of the cornea and conjunctiva. At the end of the second week, there having been no progress towards recovery, Dr. Northrup diagnosticated epithelioma, and again asked Dr. Agnew to see the patient in consultation. At that time there was a nodule about the size of a pin-head, rounded, mobile, the surface furrowed, showing some loss of substance, and towards which three or four blood-vessels were running. The diagnosis was confirmed, and Dr. Agnew recommended that the growth be removed immediately, which was done. The patient promptly recovered from the operation. Microscopical examination of the growth, made by Dr. Northrup, and also by Dr. Delafield, showed it to be an epithelioma.

Dr. Northrup remarked that epithelioma of the conjunctiva was nearly always secondary to disease of the lids. The primary affection of the conjunctiva was exceedingly rare. The prognosis usually was unfavorable, but in this case there had been no evidence of return of the disease seven months after the operation, and Dr. Northrup believed the patient was permanently cured.

BRITISH MEDICAL ASSOCIATION.

Fifty-Fifth Annual Meeting, at Dublin, August 2–5, 1887.

THE first general meeting convened at 11.30 A.M., with an unusually good attendance for the opening meeting. Dr. W. Withers Moore, of Brighton, the retiring President, made his leave-taking in a brief speech.

Dr. John T. Banks, Regius Professor of Physic in the University of Dublin, the President-elect, was conducted to the chair, and responded in an appropriate manner.

A resolution of thanks was proposed and passed to the retiring President.

Sir B. Walter Foster, President of the Council, then made the report for that body. The financial condition of the Association was reported to be in a highly satisfactory condition. The total revenue during the last

year was £25,385 2*s.* 10*d.*, whilst the expenditure was £24,395 15*s.* 6*d.*, leaving a surplus balance of £989 7*s.* 4*d.* The invested capital of the Association amounts at present to £17,566. The membership of the Association has reached about 12,000, and there are now 400 applications for membership.

Edward Hamilton, M.D., F.R.C.S.I., Professor of Surgery in the Royal College of Surgeons of Ireland, Surgeon to Steevens Hospital, Dublin, delivered the

ADDRESS IN SURGERY.

The speaker first paid a glowing tribute to Robert William Smith, an illustrious Irishman, who had filled this post twenty years before. He then reviewed the achievements of the Dublin branch of the British Medical Association, and spoke in very complimentary terms of the journal of the Association.

In an address of this kind the mind instinctively turns to retrospect of the improvements of surgery. A prominent position must be accorded in this Victorian era to the *antiseptic system of surgery*, still enveloped in the clouds of uncertainty and misconception, notwithstanding the work which so many eager and enthusiastic admirers have bestowed upon it. The system may be wrong in practice and founded on an erroneous theory, but it has spread throughout the civilized world, and that wonderful results have followed it cannot be denied. Yet we find some of its most devoted adherents abandoning parts of the system long considered as essential,—and that, too, without diminution of results. Again, we find antiseptic precautions so little regarded—nay, almost set at naught—as to prompt the ovariotomist to flush the peritoneum with water containing "germs and spores and thirty different kinds of beasts," and yet point to a continuous record of success little, if any, inferior to the more complex method. What can the simple inquirer after truth arrive at?

It may be conceded as proved that the atmosphere which surrounds our globe is infested with myriads of minute organisms subject to constant and restless change. These changes are largely influenced, if not caused, by their surroundings, and they again produce disturbance in their surroundings. Some of these can only develop in material which is dead, and are therefore amenable to physico-chemical laws. Others, again, are capable of living in tissue which is alive, where they increase and multiply, disarranging and vitiating the whole organism. In the first variety the effect produced is in direct proportion to the actual amount of the ferment introduced. In the second the amount of disturbance produced is out of all proportion to the minute quantity of the noxa which causes it. That the latter bodies are potent factors in suppuration and infective inflammation would appear to be proved beyond a doubt. Experiments have proved that injury may be produced, either mechanical or physical, on the deep tissues of the living body, and, if due cleanliness of the instruments be observed and atmospheric air absolutely excluded, no effect whatever is produced beyond the injured spot. The hot iron or injections of strong solutions of chloride of zinc kill the tissues, but the necrosed mass produces no ill effect on the surrounding structures.

It is certainly our duty to destroy and exclude from the body all these micro-organisms, and if the means adopted for that purpose—call them Listerism, antisepticism, surgical cleanliness, or by whatever name you will—turn the scale a feather-weight in favor of restoration to health or saving the life of a single human being, the man who refuses to employ them through apathy or prejudice incurs a responsibility nothing short of criminal.

A suitable germicide is now the object of pathologists and chemists. It is interesting to watch now one, now another, lauded and proclaimed, only to be superseded by a new claimant. Carbolic acid, corrosive sublimate, iodoform, thymol, have each for a time worn the crown, only in their turn to be deposed and dismissed as impostors.

Up to the present the attention has been almost exclusively fixed upon infective germs, sufficient regard not having been paid to the important influence of environment. We know that these atoms, no matter how virulent they may be, cannot undergo their life-changes, cannot produce their infective results, unless the environment, like the cultivation-liquids of the histo-pathologist, is capable of developing and sustaining this change. Deposited on a clean glass, metal, or porcelain, they die of inanition; they exercise no influence whatever, and are amenable to none. In contact with dead organic matter, or living matter in certain conditions of altered or reduced vitality, they become a teeming source of infection, decomposition, and decay. If we bring pathological surfaces to such a condition that they do not afford a suitable cultivation-ground, do we not accomplish as much as when we destroy them? Surely the perfection of antisepticism must be attained when these two conditions are fully developed and enforced.

The protection of vaccination against smallpox and the protection of the blood by the previous action of the exanthemata are examples of the influence of environment. The bacilli of splenic fever, so destructive to the herbivorous animals, take little effect on carnivora, and none at all on the pachydermata. The bacteria which will cause septicæmia in the mouse are wholly inert in the field-mouse. If we study human by comparative pathology, we learn much. Look at the flood of

light which has been shed by the study of splenic fever, chicken cholera, and of glanders; or by Pasteur's discovery of the *Pébrine* in the silkworm. We can learn much from the pathology of the vegetable kingdom. Some of the most troublesome diseases which the surgeon has to deal with are caused by the invasion of vegetable parasites. Fruit can be ripened with almost mathematical precision by interposing between specimens fully-ripened fruit of the same species, just as if the emanations from the ripe fruit produced a ripening influence upon the fruit in its immediate vicinity. I think we see this principle of environment frequently illustrated in human pathology when disease extends to adjacent but not continuous surfaces.

This twofold aspect of chronic inflammation was forced on my attention by trying to think out the best mode of dealing with chronic abscess. The discharge from a recently-opened abscess does not show any of these micro-organisms which are so characteristic of purulent matter in acute suppuration.

The treatment of open wounds by a solution of the chloride of zinc, the method introduced by the late Campbell de Morgan, has been the treatment of my colleagues and myself at Steevens Hospital for over twenty years. This has no rational foundation in histo-pathology, yet our faith in the practice cannot be shaken by the dictum of even so high an authority as Koch, who asserts that chloride of zinc is inert as a germicide, and much less effective than corrosive sublimate, iodine, or carbolic acid. I firmly believe that it will render a cut surface a barren cultivation-field, and I think we can infer that it will produce a similar effect on the wall of an abscess.

My method of proceeding is the following. A long curved trocar and canula is pushed through the abscess, and made to transfix it some four or five inches; a piece of rubber tubing, with a single hole about the centre, is then drawn through the canula by a thread connected with the cutting-end of the trocar; the aperture in the tubing being lodged midway between the trocar-wounds, the canula is removed. One end of the tube is attached by glass tubing to the exit-conduit of an irrigating can hung well above the patient's bed, the other end discharges into a reservoir at the bedside; by means of a stop-cock the flow of liquid may be regulated with greatest nicety, so that it can escape drop by drop, and render not only the contained fluid but the abscess-wall perfectly aseptic. Again, by compressing the exit-portion of the tube between the thumb and finger you can cause distention of the sac to any degree desirable, and thus produce all the advantages of the distention method proposed by Mr. Callender. And now as to the fluid which is to be used for irrigating an abscess. In my earlier trials I of course employed the fashionable antiseptic, carbolic acid, but my patients, after a few hours, exhibited olive-colored urine and gastric disturbance, warning me that I could not persist without reducing the strength of the solution to such a degree as to render it inert. Subsequently I employed a very weak solution of chloride of zinc (one part to two hundred) with the best possible results. The cavity remained antiseptic; remarkable changes were developed in the wall of the abscess; thin, membranous matter was discharged from time to time. After about a week the sinuses through which the tubes were passed became enlarged, so as to be no longer watertight. This at first caused considerable trouble in keeping the patient dry and comfortable, but more extended experience proved that at this time continuous irrigation is not needed, the cyst-wall having undergone such decided alteration in its structure that occasional syringing is quite sufficient for the perfect healing of the cavity. Such, Mr. President and gentlemen, is the treatment of chronic abscess by irrigation.

In conclusion, fellow-laborers of the British Medical Association who are engaged in surgical work, we have committed to us a goodly heritage. This Victorian age in which we live has been signalized by some most remarkable advances in all the arts and sciences. Human intellect and inventive faculties, day after day, gain fresh triumphs over matter, but in none have greater strides been made than in the art and practice of surgery, more especially in those lines where it is being extended by a more careful application of anatomy and physiology. It is true that in this country experimental research, which has done so much to relieve human suffering and save human life, is cribbed, cabined, and confined within the four corners of an Act of Parliament which is a reproach to the common sense of that august assembly, and an outrage on the characters of the members of a profession who, whatever may be their faults and failings, have never been obnoxious to the charge of cruelty or disregard of suffering or pain. The hysterical shrieks of a few women and the puling sentimentality of some weak-minded men have placed and retained in the statute-book the Vivisection Act. *Tu quoque* is, I believe, a bad defence, but we see them mount their horses and hunt to death the timid hare and clever fox. I should be sorry, indeed, to say a word against field-sports, which have no doubt their useful purpose. I only ask for consistency, and that scientists in this country should not be placed at so great disadvantage compared with their Continental brethren.

We must, however, make the best use of the means at our disposal, and carry forward the standard of investigation into new and unexplored fields. One by one the dark caverns of the body are being illumined by the light of scientific surgery; even the ivory

walls which guard and protect the dome of thought are pierced by its rays, and the brain itself mapped out with geographical precision, as in a chart, so that we can, by careful reading of the symptoms, place our fingers on the very spot oppressed by injury or disease, and by a bold and decisive operation lay it bare and remove the cause of its morbid condition or disturbed function. There still is ample room and verge enough for work,—many untrodden fields of discovery; so that the future of Queen Victoria's reign may be made as glorious in the annals of scientific discovery, and as full of help to the sick and wounded sufferer, as it has been in the past.

(To be continued.)

REVIEWS AND BOOK NOTICES.

A System of Gynecology by American Authors. Edited by Matthew D. Mann, A.M., M.D. Vol. I. Illustrated with Three Colored Plates and Two Hundred and One Engravings on Wood. Philadelphia, Lea Brothers & Co., 1887. Sheep, 8vo, pp. 789.

The contents of the first volume of this "System of Gynecology" are as follows: "A Historical Sketch of American Gynecology," by Edward W. Jenks, M.D.; "The Development of the Female Genitals," by Henry J. Garrigues, M.D.; "The Anatomy of the Female Pelvic Organs," by Henry C. Coe, M.D.; "Malformations of the Female Genitals," by Henry J. Garrigues, M.D.; "Gynecological Diagnosis," by Egbert H. Grandon, M.D.; "General Consideration of Gynecological Surgery," by E. C. Dudley, M.D.; "General Therapeutics," by Alexander J. C. Skene, M.D.; "Electricity in Gynecology," by Alphonso D. Rockwell, M.D.; "Menstruation and its Disorders," by W. Gill Wylie, M.D.; "Sterility," by A. Reeves Jackson, M.D.; "Diseases of the Vulva," by Matthew D. Mann, M.D.; "The Inflammatory Affections of the Uterus," by C. D. Palmer, M.D.; "Sub-Involution of the Vagina and Uterus," by Thaddeus A. Reamy, M.D.; "Peri-Uterine Inflammation," by Richard B. Maury, M.D.; and "Pelvic Hæmatocele and Hæmatomata," by Ely Van de Warker, M.D.

The several topics considered in this volume are treated not only in a manner consistent with the reputation of the several authors, but also—what is more rare in a work of this character—in a style remarkable for condensation and lucidity of statement. This System is worthy of unqualified praise, and if the succeeding volumes fulfil the promise of the first, it will be an honor to American gynecology, and indispensable to every physician who wishes to keep himself *au courant* with this rapidly-developing department of medicine.

NEW REMEDIES AND CLINICAL NOTES.

Hyoscine, according to Chéron, appears likely to supplant the older mydriatics, the effect being produced in ten minutes by the use of a few drops of a solution made in the proportion of one to a thousand.

Pill for Diabetes of Arthritic Origin.

℞ Lithii carb., 10 centigrammes;
Sodii arseniatis, 3 milligrammes;
Ext. gentianæ, 5 centigrammes. M.
Ft. pilulæ.
Take morning and night.—*Vigier.*

Cannabis Indica for Dysentery and Summer Diarrhœa.—The value of cannabis indica in dysentery is recognized in India, and Dr. S. J. Rennie, of Cawnpore, calls attention to it in an interesting communication to the *Indian Medical Gazette* last December. In sporadic cholera, a combination was suggested by Dr. Turner (*Lancet*, vol. ii., 1886), which he had also found useful in ordinary summer diarrhœa:

℞ Tr. cannabis indicæ,
Spiritus chloroformis, āā ♏ x;
Tincturæ kino, f℥j;
Aquam menthæ piperitæ, ad ℥j.

This has been given in all forms of diarrhœa occurring during August and September in a large dispensary, and its superiority over all the other remedies commonly used was very evident. Frederick F. Bond, M.D., and B. E. Edwards, M.B., in the *Practitioner*, extol this remedy, and prefer to combine with it a small quantity of morphine. The formula usually adopted for an adult is:

℞ Tincturæ cannabis indicæ, ♏ x:
Liq. morphinæ (Br.), ♏ v–x;
Spiritus ammonii aromatici,
Spiritus chloroformis, āā ♏ xx;
Aquam, ad f℥j. M.

To be repeated every one, two, or three hours, according to circumstances. During this period or for several hours no food is to be taken by the patient, but a little brandy-and-water. Under this treatment no cases reached a fatal issue. It is of only temporary value in tuberculous diarrhœa or in the excessive diarrhœa of typhoid fever.

MISCELLANY.

Common Forms of Adulteration in Coloring-Materials used by Confectioners and Bakers.—As a result of recent discovery of the use of chromate of lead as an artificial "egg-coloring" for cakes, public attention has been called to the subject of coloring-materials used in the trade. The American Society for the Prevention of Adulteration in

Food had just issued a circular to bakers and confectioners with reference to articles averred to be in common use:

"You are hereby notified that the enumerated colors herein are poisonous, and if you persist in the use of any of them after receipt of this notice you will be prosecuted to the full extent of the present law:

"*Common and Poisonous Colors.*

Common Name.	*Chemical Name.*
YELLOW.	
King's yellow	Sulphide of arsenic.
Cadmium yellow	Sulphide of cadmium.
Turner's yellow	Oxychloride of lead.
Turpeth mineral	Basic sulphate of mercury.
Chrome yellow	Chromate of lead.
Chrome zinc	Chromate of zinc.
Citron yellow	Chromate of barium. Chromate of strontia.
Naples yellow	Oxides of lead and of antimony.
Yellow ochre	Clay and hydrated ferric oxide.
Mosaic gold	Sulphide of tin.
RED.	
Minium	Oxide of lead.
Vermilion	Sulphide of mercury.
Purple red	Basic chromate of mercury.
Iodine scarlet	Mercuric iodide.
Realgar	Sulphide of arsenic.
Red ochre, Colcothar	Ferric oxide.
GREEN.	
Chrome green	Chromic oxide.
Cobalt green (Rimmam)	Oxides of cobalt and of zinc.
Mountain green	Malachite green.
Scheele's green	Acetate of arsenite of copper.
BLUE.	
Ultramarine	Silicate of alumina and soda with sulphide of sodium.
Mountain blue	Malachite blue.
Smalts	Silicate of cobalt and potassium.
Antwerp blue, Insoluble Prussian blue	Ferric ferrocyanide.
Soluble Prussian blue	Ferro-potassic ferrocyanide.
Indigo	
BROWN.	
Manganese brown	Binoxide of manganese.
Vandyke brown	Ferric oxide
Burned sienna, Burned umber	Clay colored with oxide of iron and manganese.
ORANGE.	
Chrome orange	Basic chromate of lead."

INTERNATIONAL MEDICAL CONGRESS.—Preparations are on foot to entertain delegates to the International Medical Congress who may wish to visit Philadelphia before going to Washington. On the Saturday preceding the opening of the Congress an informal reception and clinic will be held at the Pennsylvania Hospital, under the charge of Dr. T. G. Morton. A Committee of Arrangements has been appointed, with Professor William H. Pancoast as Chairman, some members of which will be in attendance at the St. George Hotel, in this city, morning and evening, in order to give information relative to the meeting of the Congress to those who desire it. The hotels offer reduced rates to delegates.

ACTION OF THE SUN'S RAYS ON GLUCOSE.—At a meeting of the French Academy of Sciences, M. Pasteur referred to some recent researches by M. Duclaux on the decomposition of sugar by the rays of the sun. This investigator had observed that when an alkaline solution of glucose, either in contact with the air or completely protected from the atmosphere, was exposed to the action of the solar rays, decomposition took place without the intervention of any ferment. Carbonic acid and alcohol were produced in just the same proportion as when sugar is fermented by yeast. This observation, although of no great practical importance, is of considerable scientific interest.—*Zymotechnic Magazine.*

COLOR-BLINDNESS AMONG ENGINEERS.—A peculiar phase of the labor problem was recently manifested in this city in a strike of the Reading Railroad train-men against an examination for color-blindness. It was found that some of the engineers in charge of night trains were seriously defective in their power to recognize or distinguish colors. The railroad authorities refused to yield, and the question was finally refused to be settled by arbitration.

COMPLIMENTARY BANQUET.—The personal friends of Dr. J. M. Barton tendered him the compliment of a dinner of fifty covers at the St. George Hotel on the 9th instant, to celebrate his safe return from abroad.

THE *Nashville Medical News* has been discontinued.

NOTES AND QUERIES.

OBITUARY.

DEATH OF MR. WILLIAM G. MALIN.—From the debilitating effects of the heat, acting upon a physical frame already weakened by the infirmities of advancing age, died, on the 2d instant, MR. William Gunn Malin, who, in the capacity of Clerk, Librarian, and Steward, faithfully served the Pennsylvania Hospital for the period of fifty-nine years. In 1824 he was appointed clerk to the hospital. In 1883 he was retired from active duties, and by resolution of the Board of Managers he was invited to make his home in the institution during the remainder of his life. Shortly afterwards a complimentary dinner in recognition of his long and faithful service was given to him by the ex-resident physicians, at which the managers, medical staff, and many invited guests were present. On this occasion his life-size portrait in oil was presented to the hospital. He had decided literary tastes, and made a fine collection of books relating to the history of the Moravian Church, which he presented to the Moravian Society at Bethlehem, Pennsylvania. Of late his health had been evidently failing. He was greatly respected by all who came in contact with him, and had many friends, chiefly among the older resident physicians and managers.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U.S. MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDING AUGUST 6, 1887.

IRWIN, FAIRFAX, PASSED ASSISTANT-SURGEON.—To inspect unserviceable property at New York Marine Hospital, August 5, 1887.

CARTER, H. R., PASSED ASSISTANT-SURGEON.—Granted leave of absence for six days, August 1, 1887.

BEVAN, A. D., PASSED ASSISTANT-SURGEON.—Granted leave of absence for ten days, August 5, 1887.

NORMAN, SEATON, ASSISTANT-SURGEON.—Granted leave of absence for four days, on account of sickness, August 5, 1887.

PHILADELPHIA, SEPTEMBER 3, 1887.

ORIGINAL LECTURES.

CLINICAL LECTURE ON PYÆMIA.

Delivered at the College of Physicians and Surgeons, Chicago, Illinois.

BY N. SENN, M.D., PH.D.,
Milwaukee, Wis.,
Professor of the Principles and Practice of Surgery, and Clinical Surgery, in the College.
Reported by DR. WILLIAM WHITFORD.

GENTLEMEN,—We shall consider this morning what remains of the long list of wound infective diseases,—pyæmia. With Gussenbauer, I will define pyæmia as a general infective disease, the result of the introduction into the blood of the products of septic pus; differing from other infectious diseases by the presence of multiple foci of inflammation and suppuration, and attended by an intermittent form of fever. The term pyæmia was introduced by Piorry, and literally signifies simply the coexistence of blood and pus,—*a pyo-hæmia*. Even before the relations of suppuration to pyæmia were known, it was supposed that it was the direct result of introduction into the circulation of certain noxious fluid substances (the humoral doctrine of pyæmia). Piorry recognized the direct relation between suppuration and pyæmia, and believed that the disease was due to the direct introduction of pus into the circulation. You must remember that at that time the histology of pus was very little understood; it was supposed to be simply a fluid which might permeate the vascular wall, and which, by deposition in certain regions of the body, was supposed to produce secondary or metastatic abscesses. This was the early pathological view of pyæmia,—the direct entrance of pus from the local point of suppuration into the circulation, and its arrest and localization within certain vessels in distant parts of the body.

Then came the view of Hunter, who believed that pyæmia was always the result of phlebitis; that the inflammation of the vein-wall, by producing pus, was the cause of secondary or metastatic abscesses (the phlebitic theory of pyæmia). He believed that from the tissue of the vein-walls (the seat of the suppurative inflammation) the inflammatory products gained direct access into the interior of the inflamed vessel, and that by a process of filtration, or in consequence of an arrest of the circulating pus in the blood, the numerous metastatic abscesses were produced.

Cruveilhier made the assertion that in all instances of phlebitis thrombosis was the primary cause of the inflammation; that the peculiar characteristic features of pyæmia consisted in a primary thrombosis; in short, there was, first, the formation of a thrombus in a vessel, and, secondly, a subsequent or secondary inflammation in the immediate vicinity of the thrombus. This idea was carried so far by his disciples that all inflammatory processes were by them attributed to thrombotic changes in the smallest veins: not only inflammatory lesions, but even new growths, tumors, tuberculosis, etc., were supposed to originate in small veins by the initiation of a local inflammation resulting in various pathological products. A new aspect was given to the pathology of the disease by the careful experimental investigations of Virchow on thrombosis and embolism. He showed that the metastatic deposits always occurred at points where vessels had been blocked by an embolus derived from a disintegrating thrombus. While the direct relationship existing between suppuration and pyæmia was well understood clinically, it was left for Klebs to demonstrate for the first time the direct connection of the pyæmic processes with the presence of specific microbes. In his researches into the nature of the disease during the Franco-Prussian war in 1870, he detected in the pyæmic products certain well-defined morphological elements which he called the *micrococci of pyæmia*. He found that these micro-organisms always arranged themselves in the form of "colonies" or "groups," which he termed "zoöglœa." He found this specific germ invariably present, notably at the primary seat of infection, but also in the most distant organs,—wherever, indeed, pathological changes during the course of the disease occurred.

Pasteur, in studying the puerperal form of pyæmia, detected the same morphological elements, but he found that they arranged themselves in the form of chains, consequently he called them the *microbe en chapelet*, or "chain coccus."

Vogt, when studying this subject under

the direction of Hueter, found certain germs which he called "monads" always present in all pyæmic deposits.

Burdon-Sanderson supposed that he had detected the essential cause of pyæmia in a "dumb-bell-shaped germ." From our present stand-point we can readily assume that the shape of the germ described by Sanderson was determined by the approximation of two micrococci, which when brought into close contact would resemble a dumb-bell.

The first reliable investigation into the nature of the disease was made by Koch, who not only studied the form and natural history of these germs, but produced pyæmia artificially. He found that by obtaining a putrid fluid by maceration of the skin of a mouse in distilled water, and injecting a considerable quantity of this fluid into the subcutaneous tissue of a rabbit, it induced a rapidly fatal form of pyæmia. He found that after the animal had died,—five hours to five days after inoculation,—at the point of injection there was an extensive subcutaneous abscess; and on pursuing his investigations further, he found in the various distant organs characteristic pyæmic metastatic deposits, capillary metastases, and multiple foci of inflammation and suppuration, terminating in secondary inflammations in adjacent organs, as, for instance, suppurative pleuritis the result of metastatic abscesses underneath the pleura, and suppurative peritonitis from similar processes beneath the peritoneum. By taking the serum from the œdematous portion of the pathological product and injecting it again into another animal it produced the same conditions, but in a much shorter time. He ascertained also that by diminishing the dose the interval between inoculation and the fatal termination was invariably increased, showing conclusively that in regard to time the pathological effect of the specific cause of pyæmia holds a direct relationship to the number of germs introduced. He described these germs as the micrococci of pyæmia, which in appearance resemble closely the zoöglœa described by Klebs.

Rosenbach went one step further, and examined the pyæmic deposits in man, and by cultivating directly upon an artificial soil properly sterilized he obtained the specific germs of the disease. In five out of six cases he found the *streptococcus pyogenes;* he found the *chain coccus* and the *staphylococcus* in combination in two of the five cases; and in one case only of pyæmia he found the staphylococcus alone, and this was the only case that recovered. These observations show conclusively that in the majority of cases the germs which produce the disease are the ordinary germs of suppuration first described by Ogston. Subsequent experience has shown that when the disease is produced by the staphylococcus alone it usually assumes a milder type. The results of these experimental and clinical investigations demonstrate conclusively the essential etiological connection that exists between suppurative lesions and pyæmia,—viz., that in every case suppuration must precede as a necessary antecedent pathological condition, in contradistinction to septicæmia, as I have informed you on a previous occasion, where the existence of suppuration is irrelevant: septicæmia simply being a disease due to putrefaction and absorption of wound-products, whilst pyæmia is invariably the result of an infection from a dépôt of suppuration.

We shall take it for granted that in every case of pyæmia we are dealing with the presence of the essential germs (the streptococcus and the staphylococcus), which produce at first a local suppuration, and secondly, when the disease becomes general, implicate the veins. This leads us to a consideration of phlebitis and the etiological relationship which exists between phlebitis and thrombosis on the one hand, and between phlebitis and suppuration on the other. The etiologico-clinical feature of a pus-microbe in a pyæmic patient consists in its capacity to permeate the vascular wall. The route which the specific germ of the disease selects in effecting entrance into the circulation is always through a vein or capillary vessel. As in the production of a suppurative inflammation in the soft tissues anywhere, the specific primary effect of the germ is upon the tissues with which it first comes in contact; so in cases of pyæmia the contact of the germ with the vessel-wall produces a destructive parenchymatous phlebitis. Whilst we recognize the truth of Virchow's assertion that a simple or plastic phlebitis can run its course without producing thrombosis, it is different in cases of pyæmia, as the phlebitis associated with this disease is always of an infective type and assumes a necrotic character: in other words, the contact of the specific germs

with the living vessel-wall produces a coagulation-necrosis or interstitial death of the tissues, and is consequently always followed, as a necessary consecutive result, by thrombosis *in loco* at the primary point of inoculation. We have here a pathological condition as we observe it in man, as compared with the direct and rapid results produced by Koch upon animals by the direct introduction of the pyogenic agents into the subcutaneous tissue. Clinically, we observe that the inoculation of the tissues in a wound with pus-microbes in the immediate proximity of a vein is followed by a primary pyogenic phlebitis, and, as a result of microbic action, death of the endothelial lining ensues, and the consecutive coagulation-necrosis leads to conglutination and coagulation and the formation of a thrombus. This thrombus subsequently is infiltrated with the specific germs, which again facilitate or hasten necrotic changes in the thrombus, which results in puriform softening and disintegration. Phlebitis in connection with pyæmia signifies always the production of a thrombus at the point of inflammation, and its subsequent dissemination by embolism. The *infection-atrium*, or route by which the pus-microbes gain entrance into the system, is usually through a wound,—a loss of surface-continuity somewhere which may not be detected or recognized in every instance, as in some cases of septicæmia, for the primary wound may have healed before pyæmia has occurred. But, as it is quite rational to assume that the germs of septicæmia enter the circulation only through an abraded surface, so in pyæmia the actual development of the disease is always preceded by some form of traumatism or some other appreciable antecedent pathological condition. A form of pyæmia has been recently described where no initiatory lesion can be found, and which has been referred to so-called auto-infection, which we can only explain by the entrance of the specific germs into the circulation through intact mucous surfaces and their localization in some internal organ, where they remain in a latent condition for an indefinite period of time, but sooner or later, under the influence of some determining cause or causes, produce local pathological conditions at the seat of deposition which lead to suppuration, thrombo-phlebitis, and pyæmia.

In considering the symptoms we must first allude to the local conditions in or about the wound. In patients threatened with pyæmia we usually observe a well-defined train of premonitory symptoms which precede the actual development of the disease, referable to the appearance of the wound and the general condition of the patient. The existence of the disease may be suspected at any time after suppuration has occurred, when evidences of serious capillary stasis manifest themselves at the seat of injury or operation. As the result of this intense capillary congestion at the primary seat of infection we observe a localized œdema; the margins of the wound appear puffed and elevated; the granulations pale and flabby; suppuration, which may have been profuse, becomes scanty; the pus changes its character, and, instead of a yellowish cream-colored fluid, it becomes sanious, serous, or sero-sanguinolent. On close inspection, in many instances, you are enabled at this time to detect direct evidences of thrombosis in some of the larger veins, manifested by all the symptoms resulting from venous obstruction. The general premonitory symptoms indicate a slight degree of intoxication, the result of the introduction of ptomaines from the primary suppurative dépôt into the circulation,—a general feeling of malaise; loss of appetite; sometimes a slight increase of temperature, and a slight acceleration of the pulse. The increase of temperature is followed sooner or later by the actual development of the disease, which is always initiated by a sudden, well-defined chill, which lasts from a few minutes to an hour or more. A chill of this kind must always be considered a grave symptom, as it indicates that a large amount of ptomaines has been suddenly introduced into the circulation. The chill usually recurs at irregular intervals,—one, two, or three a day, as a rule,—increasing in frequency, and often in intensity, as the disease progresses. If, for instance, during the first few days your patient has one daily chill, and, after a few days, two or three chills a day, every additional chill indicates a more advanced degree of intoxication and a wider diffusion of the ptomaines throughout the organism. New foci of infection near and remote from the primary seat of infection serve as independent centres for the production of ptomaines; consequently the

greater the area of infection the more grave the condition of the patient, and the greater the intensity of the general symptoms. The pyæmic chill inaugurates an intermittent type of fever, which in many instances resembles malarial fever almost to perfection; in fact, many cases of pyæmia have been mistaken in the beginning for cases of malarial fever, and *vice versa;* but, instead of the regular periodical chills such as characterize malaria, no regular periodicity is observed in pyæmia. You rarely, if ever, have two daily chills in malaria; but two or three or four chills in twenty-four hours are not infrequent in cases of pyæmia. As in malarial fever, so in pyæmia, the thermometer shows a rise of temperature during the algid stage, which rapidly increases, and reaches its maximum before the sweating stage. The temperature may become subnormal during the remissions or intermissions, showing that the chilly sensations are entirely subjective, as at this time the thermometer invariably indicates a constant rise in temperature. The circulatory organs, as in cases of sepsis, are deleteriously affected by the ptomaines, which act as direct cardiac sedatives. You observe the same feeble, rapid pulse, but the depression is not as marked as in most cases of acute septicæmia, as pyæmia is characterized by a slower process, a more gradual development of symptoms, and an inherent tendency to localization. The respiratory organs furnish additional and important symptoms, which, when present, are often sufficient upon which to base a differential diagnosis between this disease and septicæmia, as we shall see farther on. The secondary changes characteristic of pyæmia almost invariably occur first in the lungs; consequently we may expect that the local foci of inflammation in this organ will be attended by a change of function, as manifested by rapid respiration, etc. The clinical evidences which indicate well-defined points of localization of these secondary processes, such as consolidation of certain areas of lung-tissue each surrounded by a zone of local hyperæmia and œdema, and caused by the metastatic deposits, will be discovered at the bedside by physical exploration of the chest, which yields localized râles, increased bronchial sounds over the solidified lung, and all the evidences of diffuse multiple foci of inflammation. As in cases of septicæmia, so in pyæmia, the gastro-intestinal canal is always involved in the morbid process, as the mucous membrane invariably shows evidences of capillary stasis, œdema, or even catarrhal inflammation, which accounts for the total loss of appetite, vomiting, and diarrhœa, which are frequent and conspicuous symptoms. The nervous symptoms in pyæmia differ from those of septicæmia, inasmuch as they are not so marked; and when they are prominent they simply indicate, as in septicæmia, a rapid production and diffusion of ptomaines, which produce a sedative effect directly upon the brain and nervous system in general.

In considering the differential diagnosis you must also remember the subject of fermentation fever, which, when it occurs after an injury or operation, always appears within twenty-four hours, and is caused by absorption of fibrin ferments, and not by infection; while pyæmia never occurs before sufficient time has elapsed for suppuration to become established, which always requires at least three or four days, while it may occur at any subsequent time, so long as suppuration continues. Remember that suppuration bears a direct etiological bearing to pyæmia, and always precedes and attends this disease. Septicæmia you will recognize by the most prominent symptoms, such as a slight chill, usually not repeated, the initiatory sensation of chilliness being followed by a continuous form of fever, in contradistinction to the repeated chills and the intermittent form of fever attending pyæmia. It is sometimes more difficult to differentiate between polyarthritis of a non-pyæmic character and true pyæmia. For instance, you may mistake, possibly, an acute articular rheumatism for pyæmia, and *vice versa*, inasmuch as the disease under consideration frequently affects multiple joints, producing multiple suppurative arthritis; but you must recollect that rheumatic fever follows a well-defined course, with a definite history and a continuous form of fever, while, on account of the progressive infection, pyæmia is attended by an intermittent form of fever. Then, again, carefully consider the clinical history of the case, with special reference to the existence of a dépôt of suppuration caused by the presence of antecedent pathological suppurative products within the body caused by auto-infection.

If any doubt remains as to the nature of the local inflammation in the joint or joints, an exploratory puncture will reveal the character of the pathological product, and thus render valuable diagnostic assistance.

In cases of gonorrhœal arthritis the question of differential diagnosis becomes still more difficult, inasmuch as this form of arthritis has been considered by a number of eminent pathologists as a mild form of pyæmia, an opinion which now appears substantiated upon a pathological basis, as suppuration of the urethral mucous membrane always precedes the development of the disease; consequently the difficulty of diagnosis is diminished if you are able to trace the disease to its specific source.

The morbid anatomy of pyæmia furnishes an interesting and important subject for discussion. First, let us consider the primary focus of suppuration, caused by the direct introduction of the microbes of pus, which produce the local suppuration. The question naturally presents itself, Why do not all suppurative processes lead to pyæmia? Theoretically, an explanation can be advanced by assuming that in some forms of suppuration the pus-microbes possess a less degree of potency to infect the tissues, or else that the organism or tissues of the patient present a greater degree of resistance. Those conditions which would tend to limitation of the disease, and thus calculated to protect the patient against pyæmia, must be carefully considered in studying the causative relations between suppuration and pyæmia. The anatomical structure at the seat of the primary suppuration also exerts a potent influence in determining the occurrence of the disease; for it is a well-known clinical fact that suppurative osteo-myelitis is frequently followed by pyæmia, while suppuration in other localities, even when very extensive, is seldom followed by the extension of the suppurative process to veins. The actual development of the disease begins with a thrombo-phlebitis at the primary suppurative dépôt, from which the subsequent embolic infarcts in distant organs are derived by disintegration of the thrombus and transportation of fragments to the nearest filtrum, the lungs. The primary phlebitis is due to the pus-microbes having come in contact with and having infiltrated the vein-wall, and produced tissue-changes which favor coagulation-necrosis, consequently the formation of a thrombus *in loco*. The phlebitis at the seat of embolism is caused by the transportation of a fragment of the primary thrombus or the implantation of the specific germs upon the intima of distant vessels, producing an arteritis from within outward, in contradistinction to phlebitis from without inward, as was the case at the primary dépôt of the pyæmic process. It has been shown experimentally that certain chemical irritants, when applied to the exterior of a vein, produce a direct necrotic effect upon the intima without necessarily producing a parenchymatous inflammation of the intervening tunic. For instance, the application of nitrate of silver to the jugular vein of dogs produces a necrosis of the intima, while the remaining portion of the vein-wall remains intact. We must assume that the nitrate of silver reaches the intima by diffusion where death of the endothelial cells is produced by the chemical action upon their protoplasm. It is reasonable to assign to the action of the ptomaines a similar destructive effect upon the tissues with which they come in contact, either directly by the medium of the germs, or by diffusion. It has also been demonstrated that *digitoxin*, a vegetable substance, when brought in contact with endothelial cells by intravenous injection, produces necrosis of the intima. From these experiments it appears more than probable that the ptomaines elaborated by the pus-microbes, and brought in contact with the intima, produce similar necrotic effects, which determine the formation of a thrombus *in loco* by conglutination and coagulation in all cases where a secondary thrombus forms independently of an embolic infarct. The primary thrombo-phlebitis is doubtless produced by the deleterious effects of the pus-microbes, the ptomaines acting upon the vessel-wall in a centripetal direction, while the thrombus at the seat of metastasis is produced by an embolic infarct or the implantation of the essential germs upon the intima, where they or their product, the ptomaines, destroy the vitality of the intima. This condition is necessarily followed by coagulation-necrosis and the formation of a septic thrombus and extension of the inflammatory process in a centrifugal direction.

We have now reached the important subject of thrombosis from pathological causes. I have described to you in a pre-

vious lecture the process of coagulation as we observe it in vessels obstructed by the application of a ligature completely and suddenly interrupting the circulation, and detailed to you the minute processes which cause the formation of a non-infective or plastic thrombus. In such instances the intravascular coagulum results from the circumscribed tissue-changes in the vessel-wall following the trauma and the sudden and complete arrest of the circulation, conditions which induce coagulation-necrosis, the liberation of fibrin-ferment, and which, acting upon the remaining fibrin-producing substances (fibrinogen and fibrino-plastic material), causes the formation of a thrombus. Such a thrombus, due to aseptic causes, soon becomes infiltrated with the products of tissue-proliferation from the vessel-wall, and having performed its temporary function as a nidus for the plastic material, is completely removed by substitution on the part of the intra-vascular granulation-tissue, which by cicatricial contraction effects the definitive closure of the lumen of the vessel. Pathologists have been for years endeavoring to find a tangible explanation of the formation of the white mural thrombus during life which has been so often found upon post-mortem examination, and for the occurrence of which no satisfactory explanation could be given. The older pathologists interpreted the existence of a white mural thrombus by considering it as a remnant of an antecedent red or coagulation thrombus, decolorization having taken place by escape or destruction of the red corpuscles. Recent investigations, more especially the researches of Eberth and Schimmelpfennig, have shown that the white thrombus within a vessel during life has a different significance, as far as its production and duration are concerned. Such a thrombus is not caused by coagulation-necrosis alone; it consists almost exclusively of the third corpuscles of the blood, which become deposited by conglutination upon a projecting devitalized surface of the intima.

The interesting and valuable experiments of Eberth, for instance, have demonstrated that whenever a foreign substance encroaches upon the axial current of the circulation it mechanically arrests the third corpuscles which come in contact with it, a process which is termed conglutination, and which results in the formation of a white thrombus. If a thread be passed through an artery or vein of a living animal, it becomes the nucleus for a white thrombus which is composed almost exclusively of the third corpuscles. It has been claimed that these minute disks were the result of disintegration of pre-existing red or white corpuscles, the product of a retrograde change. But careful physiological investigation has verified the existence of a third element in the blood, whose function so far has not been definitely determined, but which, as we have seen, constitutes the most important element in the formation of a mural thrombus and the gradual obliteration of the vessel.

Another important element in the production of a thrombus in an inflamed vessel is the white corpuscle, which under such circumstances, in virtue of an increased viscosity, manifests a strong tendency to mural implantation, which, when the vessel is already the seat of mural thrombosis, accelerates the growth of the thrombus, and consequently the obliteration of the vessel. In capillary vessels, the seat of localization of the pus-microbes, rapid and complete stasis takes place by mural implantation of the viscous white corpuscles, which arrest the axial current, producing capillary thrombosis.

I hope I have made this subject sufficiently intelligible for you to appreciate the process of thrombosis as we observe it in cases of pyæmia. In recapitulation, it can be said (1) that the thrombo-phlebitis at the point of primary infection is caused by the action of the pus-microbes on the vessel-wall, causing tissue-changes which determine thrombosis. (2) The thrombus thus produced is an infective one, incapable of removal by granulation-tissue, destined to undergo disintegration, and by detachment of fragments it gives rise to embolism. (3) When pus-microbes have gained entrance into the venous circulation, they may produce thrombo-arteritis in distant parts by implantation upon the intima, where they give rise to necrobiotic changes which determine thrombosis and extension of suppurative inflammation to the remaining tunics and the paravascular tissues, which leads to the formation of metastatic abscesses.

On examining a recent thrombus in a case of pyæmia, you will always observe the zoöglœa in its peripheral portion show-

ing distinctly the etiological relations which they bear to it. When a sufficient period of time has elapsed for the germs to infiltrate the thrombus, they impart to all the elements of that thrombus the infective properties which characterize the primary dépôt of infection. The infection becomes general by dissemination of the pus-microbes set free by the thrombus and diffusion of the ptomaines through the circulation, these giving rise to the toxæmia which constitutes one of the most conspicuous clinical features of pyæmia. The infective germs which enter the veins at the primary infection-atrium reach the lungs as the first filtrum through the intervening venous channels directly, or through the medium of the white corpuscles or detached fragments of a disintegrated thrombus, where they initiate a septic thrombo-arteritis which constitutes the nucleus or starting-point for the formation of metastatic abscesses in this organ. In case the infective germs or fragments of a thrombus pass the first filtrum, they enter the left side of the heart, and by dissemination through the systemic circulation lead to metastatic abscesses in the most distant organs in the same manner as in the lungs. One of the characteristic features of pyæmia aside from the demonstrable embolism and metastatic abscesses is the existence of extensive capillary stasis, caused by direct implantation upon the lining of the capillary wall of floating germs, which so alter the tissues as to determine mural aggregation of the white corpuscles and complete closure of the lumen of the vessels by conglutination of the third corpuscle, conditions which finally result in the formation of a capillary thrombus.

The question, important to pathologists, as to the true relationship of phlebitis to thrombosis, has recently been satisfactorily explained. If thrombosis follow a non-infective plastic phlebitis, we shall find the thrombus surrounded by the inflamed vascular tunics, with a beginning infiltration of its periphery by the products of cell-proliferation from the fixed tissue-cells, as well as by migration corpuscles. The appearance of the vascular walls, as well as the condition of the thrombus, indicates that the inflammatory processes preceded the formation of the thrombus, and consequently must be considered as the direct cause of the intravascular coagulation-necrosis. If the reverse be the case,—if the thrombus be the cause of the phlebitis, as in cases of thrombosis after embolism, or after complete obstruction in a vessel from other causes,—on examination it will be found that the thrombus has undergone changes which antedated the inflammatory changes in the tunics of the vessels, and therefore must be looked upon as the direct cause of the phlebitis.

Having described thrombosis as it occurs in pyæmia at the primary point of infection and in distant organs, I will now call your attention to embolism. You must bear in mind that a primary thrombus is always caused by local causes in the vessel; its growth is gradual; consequently it does not give rise to sudden obliteration of a vessel, and in the majority of cases when due to pathological causes it is found in veins. Embolism, on the other hand, implies the sudden obliteration of a vessel, always an artery, by the impaction of the lumen of the vessel by a foreign substance or pathological product, which is carried in the direction of the blood-current until its further progress is mechanically arrested, and in consequence the circulation is suddenly and completely interrupted beyond the seat of the obstruction, unless subsequently restored by collateral circulation. Both of these forms of vessel-obliteration are met with in pyæmia. A plastic thrombus, as we have already seen, is capable of undergoing complete absorption by a process of substitution on part of the granulation-tissue springing from the fixed tissue-cells of the vessel-tunics; but an infected thrombus, the seat of infection of pus-microbes, is not capable of undergoing such favorable retrograde changes. This variety of thrombus disintegrates at an early stage by gradual granular degeneration of its component parts under the influence and by the cause of these specific microbes. There is no absorption, but a softening takes place primarily in the centre; the necrotic changes which take place convert the thrombus into a material which microscopically resembles pus. It was this septic disintegration of a thrombus which formerly induced pathologists to assume the direct entrance into and the presence of pus within the vessels. Virchow showed many years ago that the product of a broken-down thrombus is not pus, but that it is a granular *débris*, the

result of retrograde degeneration of the histological elements of the thrombus itself. When the thrombus is produced by a peripheral microbic cause, disintegration often begins between the vessel-wall and the thrombus, and the necrobiosis attending this process gives rise to early transportation of minute particles of the thrombus to distant parts of the organism, causing capillary embolism in the lungs and other organs. When a large fragment of a projecting or disintegrated thrombus becomes detached and is conveyed along the venous current to the lungs, rapid and sudden obliteration by embolism of the pulmonary artery takes place, and sudden death by asphyxia is produced, a frequent form of fatal termination in pyæmia. The thrombus, by additional deposits of the products of coagulation-necrosis, has an inherent tendency to grow in a central direction. By complete arrest of the circulation at the point of obstruction, with a diminished heart's action, the venous current on the proximal side of the clot is diminished in force, a condition which favors coagulation-necrosis, and consequently also the growth of the thrombus. A thrombus starting in a small vein in the immediate vicinity of an infected wound, by its growth in a central direction, gradually invades larger vessels, and when such is the case the projecting portion into the free lumen of an adjacent larger vein may become detached by the blood-current, and after passing through the right side of the heart is arrested in the pulmonary artery, where it causes a sudden ischæmia of the lungs and death from asphyxia. The formation of infarcts in the pulmonary artery is thus easily explained in pyæmia, but it is more difficult to account for the presence of emboli in more distant organs.

The question presents itself, How are we to explain the formation of metastatic deposits beyond the first filter, the lungs, in more distant parts of the body, as the liver, kidneys, pancreas, brain, and joints? It is impossible for the fragment of a thrombus of any considerable size to pass directly the pulmonary filter, as it is mechanically arrested in some of the branches of the pulmonary artery. The embolus under these circumstances becomes the nucleus for a new or secondary thrombus, which by extension through the pulmonary capillaries may reach directly the systemic circulation, where it serves as a new focus for the dissemination of the specific germs and furnishes the material for systemic embolism. The germs in this secondary thrombus have a more ready access into the general circulation, and by implantation upon the walls of the capillary vessels initiate a pathological condition the same as I have described in the vessels at the primary infection-atrium. I have already informed you that these so-called metastatic abscesses are not true abscesses *ab initio;* their close resemblance to pus led Virchow to apply the term "puriform" transformation in contradistinction to "purulent." He knew that while pus within the vessel was usually absent, if life was sufficiently prolonged the inherent tendency of these deposits was to produce pus, the result, as he thought, of inflammation not within the vessels, but in the tissues adjoining the thrombosed vessel. This, we have seen, is accomplished either by the transportation of infected fragments of a thrombus and embolism, or by direct implantation of the infective germs upon the capillary walls. These germs, again, reach the paravascular spaces either directly or through the agency of wandering cells, and establish here a suppurative inflammation, with the formation of an abscess around the obstructed vessel: a purulent periphlebitis or periarteritis. This is usually the pathological condition we expect to meet with in cases of slow chronic pyæmia as compared with the rapidly fatal form where there is not sufficient time for secondary metastatic suppuration to take place.

In recapitulating the etiology and pathological anatomy of pyæmia, I wish to recall once more the local formation of an infected thrombus at the site of injury or operation, the infection always being due to the presence of pus-microbes, which by implantation upon the intima produce necrosis of the endothelial cells and gradual narrowing of the lumen of the vessel by conglutination of the third corpuscle, which form a mural thrombus, complete obstruction of the vessel being finally accomplished by coagulation-necrosis. An infected thrombus, as we meet with it in pyæmia, is seldom, if ever, removed by absorption; its tendency is to disintegrate and to disseminate the first local pathological conditions by embolism.

Modern research has come to our assistance in correctly interpreting the formation of pus in parts distant from the

primary focus of suppuration. A secondary abscess can only occur after pus-microbes enter the circulation and have found favorable conditions for localization and reproduction in some distant part.

In regard to the prognosis of pyæmia, it may be safely stated that it constitutes one of the gravest complications in surgical patients. When the disease is once fully established, with very few exceptions indeed, it always proves fatal. For reasons we do not as yet fully comprehend, its duration varies greatly in different cases. It may prove fatal in a few days, or the disease may be prolonged for months; and in one of Billroth's cases the patient lived for more than a year. In the acute, rapidly-fatal form, death is produced by ptomaine intoxication from rapid, general dissemination of microbes, —a septico-pyæmia by embolism of the pulmonary artery or implication of some vital organ in the process. Fortunately, even in this dreadful disease we observe efforts on the part of the organism towards localization, and, as the few cases of recovery would tend to prove, a time finally comes when the system becomes tolerant of the germs or the germs ultimately lose their potency. It is a strange fact about pyæmia that while the clinical tendency of the disease, from the very nature of its essential cause, is to progress, the process of this gradual invasion is always attended by pathological conditions which are calculated to retard or arrest infection. In this regard we observe a marked difference between sepsis and pyæmia. In septicæmia the germs are rapidly diffused throughout the entire circulation, and we observe a complete absence of any intravascular conditions calculated to prevent this rapid dissemination. The general condition of a septic patient indicates the existence of an uninterrupted, continuous production and diffusion of ptomaines which soon results in death by toxæmia. In pyæmia, step by step, the system seems to fight against the diffusion of the microbic cause by establishing mechanical barriers in veins, capillaries, and arteries by thrombosis and embolism. This difference must be due to the intrinsic properties of the germs themselves. The microbes of pus produce local conditions favorable to the retardation or arrest of infection at the primary infection-atrium and the distant points of localization. The inflammatory changes within and without the vessel-wall produced by the presence of pus-microbes are well calculated to limit the infective process and explain satisfactorily the chronicity of pyæmia as compared with septicæmia. The pathological feature of pyæmia which determines the unfavorable result principally consists in the inherent tendency of the germs, wherever they may be, to reproduce the identical processes in various parts, and thus indefinitely multiply in the organism the primary local conditions which finally cause death from exhaustion or intoxication, while at the same time the patient is constantly in danger of death by pulmonary embolism or visceral disease of important organs. For instance, a small suppurating pulmonary infarct may produce an empyema which may become the direct cause of death. Again, a small infarct in the liver may become the nucleus of an enormous abscess of the liver, which in itself would constitute a sufficient cause of death. Finally, the transportation of a minute fragment of an infected thrombus into the vessels of the brain may lead to a cerebral abscess with a rapidly-fatal termination solely from this cause.

The danger to life from multiple suppurative polyarthritis, a frequent condition in pyæmic patients, is well known. In the absence of serious visceral lesions, it must be looked upon as a frequent and direct cause of death. While we are more familiar with the manner in which metastatic abscesses are produced in pyæmia, the occurrence of suppurative arthritis is more difficult to understand. It is possible that the synovial membrane is affected in the same manner as the peritoneum in the animals inoculated by Koch, where we have reason to believe the germs reached the peritoneum through the connective-tissue spaces. If this explanation should prove to be correct, it is evident that the occurrence of suppurative arthritis in pyæmia would indicate a grave form of the disease, as it would imply extensive diffusion of microbes beyond the boundary of vessels, and at least in many instances necessarily accompanied by multiple dépôts of suppuration in other parts of the body. As a rule, it can be said that time is an important element in prognosis. In acute cases the processes characteristic of pyæmia progress rapidly from the seat of infection

to distant parts and organs, and the disease is progressive in every sense implied by that term.

Wherever antiseptic surgery is practised thoroughly and intelligently, pyæmia seldom, if ever, occurs. As the disease can only occur after suppuration has been established, it is evident that all measures calculated to prevent suppuration also prevent this disease, and where suppuration has occurred, rigid antiseptic treatment diminishes the danger of pyæmia.

If the curative treatment of the disease has been and always will be unsatisfactory, we are now—thanks to antiseptic surgery—enabled to prevent it almost with certainty in all cases of intentional wounds. It is easier to prevent this disease than to cure it. If antiseptic surgery furnishes almost absolute protection against suppurative inflammation, you can readily conceive that it furnishes the only absolute protection against pyæmia. You must become fully aware of the importance of this assertion in the treatment of small and apparently insignificant wounds, as any suppurating wound may become the starting-point of pyæmia. The prophylactic treatment consists, in brief, in preventing the entrance of pus-microbes into wounds, and in case of contaminated wounds to effect their removal or to destroy their power of reproduction by reliable antiseptic agents, and to guard against accumulation of pus by securing free drainage. Clinical experience and scientific research corroborate the statement that pyæmia is prevented with certainty by preventing suppuration.

It becomes, therefore, your duty to perform every operation, no matter how insignificant, under strict antiseptic precautions, in order to protect the patient against the remotest possibility of incurring this disease. You must treat all accidental wounds as infected wounds, and resort to such a course of disinfection as will transform them into aseptic wounds. I have already informed you that pyæmia is very prone to follow suppurative inflammation in certain tissues and localities where the entrance of germs into veins is favored by anatomical peculiarities. The older surgeons feared wounds of veins and the medullary tissue of bone, on account of the well-known fact that when these tissues were the seat of suppuration pyæmia was liable to follow. Acute infective osteomyelitis and suppurative inflammation of the internal ear and the mastoid process are prone to be followed by pyæmia for the same reason. You will readily appreciate the importance of adopting timely prophylactic measures in the two latter conditions by exposing the seat of suppuration by operative treatment for the purpose of effecting a mechanical removal of infected tissue, and thorough disinfection with a view of preventing the occurrence of an infective thrombo-phlebitis or sinus-phlebitis and pyæmia.

In the consideration of the curative treatment the question naturally presents itself, Can anything be done after we are able to ascertain that the disease exists? Theoretically, it would appear that as long as the infected area remains sufficiently circumscribed and amenable to direct operative removal we should not despair, but should resort to prompt and efficient means to remove the infected tissues, and especially the thrombosed veins, by operative measures. Practically, it would be exceedingly difficult to ascertain whether, in any special case, the infection had not passed beyond all possible reach, and thus rendered any operation useless, and on this account unjustifiable. Where the disease takes a starting-point in a limb, as the medulla of a bone, it is only proper to remove, as thoroughly as possible, the infected tissues by scraping and ignipuncture, or by resorting to a timely amputation. In suppurating wounds not admitting of such heroic measures, the surgeon must content himself with securing free drainage, or with resorting to permanent antiseptic irrigation with a one- or two-per-cent. solution of acetate of aluminum. It is only proper to insist that the parts the seat of thrombosis should be left perfectly at rest, so as to prevent the detachment of fragments by mechanical violence, an accident which is always followed by grave consequences. In all cases where internal metastatic deposits have taken place, it is too late to remove, with any hope of success by operative treatment, the infected tissues at or near the primary place of infection, as the disease will in all probability multiply itself from these distant centres. In such cases it is advisable to support the heart's action with large doses of alcoholic stimulants, from one to two pints of brandy daily, with a faint hope that, by prolonging life for a sufficient

length of time, the disease may, as it were, exhaust itself, and the patient recover after a long and lingering illness. In all pyæmic patients it is advisable to give a daily antipyretic dose of quinine during the remissions, and to support the strength of the patient by concentrated, nourishing liquid food.

ORIGINAL COMMUNICATIONS.

CLINICAL VALUE OF ANTIPYRETICS.*

BY LEROY J. BROOKS, M.D.,
Norwich, New York.

IT has been demonstrated that physiological heat-production is the result of metabolic changes in the tissues, and that a delicate balance is maintained between production and dissipation by heat-regulating centres.

Wood finds a heat-producing centre near the conical sulcus of a dog, while Aronson and Sachs locate it near the inner side of the corpus striatum. The pathological evidence consists in the fact that crushing the cervical medulla produces a most exorbitant rise of temperature. Cases are on record of a temperature of 122° produced by injuries to the spinal cord. Moreover, a more intimate study shows that total section of the cord near the pons produces a rise of temperature, but that if the anterior columns are spared such a rise does not take place.

In divisions of certain portions of the cord which especially influence the vasomotor system, as well as in disease of the same portions, there is produced a marked lowering of temperature. The question is of importance to us in determining whether pathological heat-variations are the result of a disturbance of the physiological heat-regulating powers through impressions upon the nerve-centres, or some foreign element introduced into the blood has elevated the temperature by an increase of the tissue-changes. In these days of microbes we find that the claim has been made that fever-heat is the result of a struggle between the system and certain microbic foes.

The suggestion leads at once to the inference that if temperature-elevation be due to changes produced by the presence of bacteria in the blood, or if the fever is the result of some poisonous secretion or material produced by bacteria or of some specific poison acting directly upon the blood, then such remedies as would destroy the activity or life of bacteria, or of such specific poisons, would reduce the temperature. Were the theory a correct one, then antisepsis and antipyresis would be synergistic and synonymous terms.

It leads us to ask, Are antiseptics, then, antipyretics? If so, are they antipyretic because of their antiseptic qualities or because of some other specific action of the drugs?

As we investigate, we find that many of the strongest antiseptics are the feeblest antipyretics.

We need but to mention corrosive sublimate, which is fatal to lower organisms in one part to twenty thousand,—which is ten times more powerful than thymol and benzoate of soda, twenty times as strong as creasote, thyme, and benzoic acid, thirty times as powerful as salicylic acid and eucalyptol, and one hundred times as powerful as carbolic acid and quinine as an antiseptic,—yet no specific antipyretic effect can be attributed to it. 2d. Some of the most active antipyretics are feebly antiseptic,—instancing quinine, carbolic acid, and the benzoates. 3d. As a rule, it is impossible to introduce into the blood of a living organism, and maintain the presence for any considerable time, of a sufficient amount of an antiseptic drug to destroy the activity or life of bacteria therein. It is probable that corrosive sublimate is the one agent that could attain nearer this end than others, but this it could not accomplish without extreme toxic effect.

Again, it is maintained by many that bacteria may exist in healthy, circulating blood (doubtful); that they may exist in diseased conditions without causing an elevation of temperature, as in diphtheria, afebrile pneumonia, hydrophobia, and malarial diseases; and that, while the actual abundance of bacteria in the blood may bear a relationship to the severity of the disease, it does not to the degree of temperature-elevation.

The antipyretic qualities of antiseptic drugs are not manifest until a secondary effect is produced,—namely, a profound impression upon the central organs.

* Read before the New York Medical Association, Third District Branch, at its annual meeting held June 16, at Elmira, New York.

To give the specific authorities for these statements would lead us too far from the purpose of our paper. We then venture the statement that antisepsis does not necessarily mean antipyresis, and present the following class of antipyretics: first, those that retard heat-production; second, those that diminish heat-production and increase heat-dissipation; third, those that increase heat-dissipation. The first class includes quinine; the second, the salicylates, antipyrine, antifebrine, thalline, kairine, hydrocinchonine, and others of the same derivation; the third, aconite, gelsemium, veratrum, and similar remedies, to which may be added cold applications.

Quinine is the most prominent, and it may be said to be the only drug that by its direct specific action diminishes the production of heat alone. This cannot be due to its effect upon malarial poisons, for we find that it will reduce temperature with equal force in pneumonia, typhoid, erysipelas, eruptive diseases, surgical fevers, etc., which do not possess any malarial element.

It cannot be due to its antiseptic qualities, for Binz and others have shown the minimum quantity of quinine necessary to prevent the development of bacteria to be one part to one thousand. It is evident then that with an average of eighteen pounds of blood, it would require one hundred and thirty-eight grains of quinine circulating therein to meet such conditions. Quinine is discharged at so rapid a rate from the blood that we may readily conclude that it would be impossible to administer with safety to the patient a sufficient quantity to affect the bacteria.

Quinine lessens tissue-metamorphosis and diminishes the activity of white blood-corpuscles, but to that cannot be ascribed its profound antipyretic effect. It will lower temperature in the healthy body. It will reduce temperature without a marked exhibition of effect upon the arterial or respiratory system, and without exciting perspiration. We conclude, then, the effect of quinine upon the temperature-elevation is the direct result of a direct and specific action upon the heat-producing centres. We are confirmed in this when we find that it is the only drug which will completely and permanently act upon heat-production so as to prevent the recurrence of fever non-malarial in its origin.

The specific effect of the single dose of quinine on temperature begins in two to three hours, reaches its maximum in five to six hours, and continues from twenty-four to seventy-two hours, and the reduction is sometimes permanent.

The second class, those which both diminish production and increase dissipation, —of which the salicylates, antifebrine, and antipyrine, and drugs of the same derivation may be considered as types,—possess the following peculiarities in general: 1st, their effect upon heat-production is less profound and more variable than quinine; 2d, they rarely destroy the tendency to overheat-production; 3d, they increase heat-dissipation; 4th, except in extreme doses or previous cardiac weakness, they show but a moderate effect upon the heart or respiratory organs; 5th, except where idiosyncrasies exist, their specific effect upon the body-temperature is the result only of sufficient dosage to produce a profound or toxic impression upon the nerve-centres.

The salicylates are second only to quinine, possessing a greater power over temperature-production than antipyrine and its class, and more influence over heat-dissipation than quinine. They rarely destroy the tendency to recurrence of fever, though more often than the others of the second class. They have a moderate effect only upon the heart and arterial tension or respiratory organs. While salicylic acid is strongly antiseptic, its combinations with alkalies are not.

It has been proved that salicylic acid unites with the soda of the blood to form salicylate of sodium. (Bartholow.)

We may reason, therefore, that their antipyretic qualities are not due to their antiseptic powers. Salicylate of sodium will often produce a fall of temperature without causing sweating. (Ross and Nothnagel, p. 468.)

There is rarely any serious after-effect from its administration, except after giving extreme doses. (*Idem*, p. 475.) To obtain antipyretic results large and frequently-repeated doses should be given, when the effect upon temperature begins in one to two hours, reaches its maximum in three to six hours, and generally ceases in twenty to twenty-four hours.

Antipyrine and antifebrine may be taken as types of the remainder of this class. In dosage antifebrine is about twice the strength of antipyrine. Both are easy of

administration. Their specific action upon temperature is temporary, commencing in one-half to two hours after administration of proper dose, reaching the maximum in three to five hours, the effect being then rapidly dissipated. They probably do not prevent the recurrence of a specific fever; they do not possess antiseptic qualities sufficient to influence the condition of the blood, and no perceptible effect upon the white blood-corpuscles; their effect upon heat-dissipation is much more pronounced than with the salicylates; they have a positive effect upon the nervous system, allaying headache, producing sleep, and quieting delirium; they influence the vaso-motor system; they increase perspiration and urine. Serious after-effects, except with extreme doses or previous cardiac weakness, have not been noted. They diminish arterial tension moderately. An occasional measle-like eruption has been noticed as being produced by antipyrine, which readily disappears when it is discontinued. The drugs are applicable to any disease with temperature-elevation.

The third class includes, as we have already stated, aconite, gelsemium, veratrum, and cold. They have no specific action on temperature-production, and centre their effects upon heat-dissipation. They tend to paralyze the heart and respiratory organs, reduce arterial tension, and are sedative to the vaso-motor system. It is claimed that they produce first an increase in the actual temperature by the influx of blood in the paralyzed vascular fields, then a sluggishness of the current, greater evaporation, and a resulting cooling of the surface. A hot bath, antimony, an emetic or cathartic, may reduce temperature in the same manner as other motor-paralyzers; cold acts in a more mechanical way by abstraction of heat. The effects of the class upon increased temperature are temporary, disappearing as soon as the drug-effect has ceased. They are applicable to sthenic cases,—acute febriculæ, inflammations,—and act where doubtless heat-production is normal and heat-dissipation diminishes.

Practically, then, we arrive at the following conclusions concerning pyrexia. Fever-heat is a loss of balance between the producing and dissipating heat-functions. There may be an increased production with dissipation normal, or diminished dissipation with production normal, or other combination of the different conditions. Thus we may have an actual oral temperature of 104° without increased production, which in itself would not be serious; on the other hand, increased production may concur with increased dissipation, not indicating a high temperature-elevation, yet being disastrous in its effects upon the patient. We not infrequently see this in adynamic diseases, where there occurs the prostration, subsultus, delirium, rapid emaciation that we would naturally associate with intense fever, yet without marked increase. Again, we see the further extreme where, production remaining normal or subnormal, an intense impression upon the nerve-centres—the vaso-motor paralysis, with cardiac and respiratory depressions,—we get the excessive dissipation and the resulting collapse of cholera, the nervous shock, the cold stage of ague, the congestive chills, the collapse of yellow fever, etc.

McAllister, in his recent studies of fevers, demonstrates that in fevers there is disturbed, first, the thermotaxic, or heat-regulating; second, the thermogenetic, or heat-producing; and, lastly, the thermolytic, or heat-losing functions. In the beginning of a fever, then, the important indication is to restore, if possible, the disturbed thermotaxic and thermogenetic functions: to give a drug, if we possess one, that will prevent, modify, or shorten the disease. It is not necessary to enter literature, nor illustrate by cases, except to say that an analysis of the opinions of Liebermeister, Niemeyer, Reynolds, Da Costa, Flint, Cleveland, and others, compels the conclusion that quinine aborts some, shortens the duration of others, and ameliorates most cases of fever.

In the advance of the fever it presents a somewhat different aspect. With the hope of aborting the disease gone, the thermogenetic and thermolytic functions disturbed, more or less tax upon heart and respiratory organs and the nervous system involved, we look for remedies where production of heat can be diminished without serious depressions, the elimination increased, and the nervous system quieted, and we find that the salicylates, antipyrine, and antifebrine meet most admirably these needs. Every-day experience proves this beyond peradventure if, as we have no reason to doubt, "the dangers of fevers are more from the prolonged and continuous temperature-

elevation and the resulting disaster to the bodily tissues" than from any other cause. The speedy dissipation of the antipyretic effect is preferable to the more enduring and profound, but proportionately depressing—at this stage—effect of quinine. Again, quinine in antipyretic doses increases cerebral disturbances. Antipyrine and antifebrine allay delirium and possess a distinct hypnotic action. Out of eighteen cases of typhoid fever in which antipyrine or antifebrine was used, we recorded two instances of apparently undue depressant action as a direct result of the drugs. In each instance the administration was towards the close of the fever,—one patient 9 years old, the other 18 years. In the younger the temperature had been normal for three days; through an excitement it rose to 103.5°, and the mother gave ten grains of antipyrine. I found the patient with feeble pulse, some cyanosis, cold extremities, nausea, temperature 97°. A few doses of carbonate of ammonia and whiskey brought a quick restoration. In the second the temperature had risen to 103°, when ten grains of antipyrine were given by the nurse, and the dose repeated in an hour without taking the temperature. The symptoms an hour later were similar to those of the first case, and, like that, soon responded to stimulants.

The lesson of the two cases is that, at the closing stages of a fever, the order is reversed, and we have, first, a restoration of the thermolytic; second, the thermogenetic; and, lastly, the thermotaxic power. Just here nature tries to conserve her forces for the natural reaction of fevers, when the taxed muscles, the weakened heart and respiratory organs need the most judicious management. To give at this stage an antipyretic—that is, to diminish production or create an over-elimination—might be easily disastrous. We should withdraw all antipyretics, and resort to stimulants and tonics. Cold should be used in the earlier and middle stages of a fever, where by its mechanical effect it assists in the general purpose of fever-reduction and subserves the comfort of a patient.

From the records of the eighteen cases referred to in which antipyrine was used, we note that there were two cases of intestinal hemorrhage: one several days after convalescence had begun, and nearly ten days subsequent to any use of antipyrine, caused the patient's death. In the other hemorrhage was slight and of short duration, and had no relation to drugs administered. There were two deaths: one from hemorrhage, as above stated, and one from excessive cerebral complications and previous bad condition.

Occasionally a peculiar susceptibility exists, and full effect is obtained from small doses; and, again, in some instances the maximum doses were required to get the desired result. We found but one case where the measle-like eruption appeared.

The third class of antipyretics should only be used in the active sthenic stages.

The typical treatment of fevers should be:

First thermometric stage: abort; modify; shorten duration by quinine assisted by heat-dissipaters.

Second thermometric stage: keep temperature below 103° by salicylates, antipyrine, antifebrine, assisted by cold applications, lowered surrounding temperature, hydrogenized food.

Third thermometric stage: feed; stimulate; use nerve-sedatives and tonics.

Lastly. The antipyretic effect of quinine commences about the third or fourth hour; reaches its maximum in the sixth or eighth hour; continues its effect from twelve to seventy-two hours, and sometimes permanently. Salicylates commence the second or third hour, reaching the maximum in four to six; and continue their effect twelve to fifteen hours. Antipyrine, antifebrine, and this class commence their effect in one-half to one hour; reach the maximum in two to three hours; continue their effect three to six hours. Aconite, gelsemium, etc., commence their effect within the first hour, reaching the maximum in from two to five hours; the effect dissipates soon after ceasing administration of drug.

NEW METHOD OF MANAGEMENT OF THE PATELLA IN AMPUTATIONS AT THE KNEE-JOINT.

BY Z. H. EVANS, M.D.,
Bay City, Michigan.

ON the 13th day of August, 1872, I was called to see Rev. Harvey Peirce, aged 65, minister of the gospel, who had just sustained a compound comminuted fracture of the upper third of the leg, implicating the knee-joint, caused by the kick of a horse. The case being one demanding

amputation at the knee-joint, I proceeded at once, with the assistance of Dr. Hosmer, to operate by making long posterior and short anterior flaps (Hoin's method).

In making my flaps I cut the posterior too short, so much so that if I had removed the patella I would still have lacked sufficient tissue in my anterior flap to have brought it in proper apposition with the posterior. In this extremity I decided to excise the condyles at their face, which having removed, my flaps came nicely together, bringing the *patella immediately over* the end of the shaft. The patient made a speedy recovery, riding out to church in a few weeks from day of operation. In a subsequent case of exsection of the knee-joint followed by gangrene of the foot, making it necessary to remove the leg, I operated as in my first case (the condyles having been removed in the first operation by exsection), with good result. The patient died a year after with apoplexy, and upon post-mortem examination of the stump I found the patella firmly united to the end of the femur by *bony* deposit. I am of the opinion that bony union of the patella and end of the femur will take place without sawing through the lower surface of the patella, as practised by Gritti and modified by Stokes and others. I am disposed to believe that, by reason of the greater firmness and less liability to tenderness of the stump, also in the degree of retention of the purchase of the quadriceps muscle, this operation is preferable to those recommended in our late works on surgery. By this method the leg retains its full strength for future use in the adaptation of an artificial member.

THE USE OF COLD WATER IN THE TREATMENT OF TYPHOID FEVER, WITH TWO CASES.

BY S. P. ALLEN, M.D.,*

Whitney's Point, New York.

WITHIN the last few years much has been said and written, I am aware, upon the use of so-called antipyretics in the treatment of typhoid fever, and, if properly used and carefully watched, they are undoubtedly of great importance in the treatment of these cases. But, on the other hand, if used indiscriminately and by way of routine, they may be, and no doubt have been, worse than no treatment. I think that it is admitted by all at the present time that typhoid fever belongs among the so-called self-limited diseases, and that the majority of cases occurring in civil practice where the temperature does not rise above 103° would recover without much if any medication further than absolute rest, with plenty of good air and careful diet.

That there are exceptions to this rule I am free to admit, and it is in just those cases that the antipyretic treatment is capable of being useful and doing most good.

There have been various remedies used for this purpose, and no doubt all have done some good, and each have their advocates. Among those that have been used most I might mention quinine, antipyrine, and cold water. But it is only of the latter that I wish to speak, and I will give the history of two cases among the many that have occurred in my own practice, and that were treated mainly by the use of cold water. I select these cases because of the extreme high temperature that prevailed during so much of the time in the course of the disease.

Case I.—October 11, A.M. Was called to visit A. P., aged 21, by occupation a farmer, and all his life up to this time had been strong and healthy and accustomed to hard work. He had been sick five days when I first saw him, and at this time the following symptoms were present. Epistaxis had been quite persistent, at times, for three days; face dark, almost purple; slight cough; iliac tenderness; ochre stools; drowsy, with more or less muttering when not disturbed; severe headache, also complained that the light hurt his eyes; tongue dry, with heavy, dark coat; pulse 100, temperature 103°. Treatment: ordered him to be sponged with tepid water every two hours. I gave as a sedative aconite and spirits of nitre.

October 12, 9 A.M. Temperature 104°; other symptoms about the same. I then wet a sheet in water at 70°, folded it and wrapped it around his body, and used water at 65° to sponge his limbs and arms, and at intervals of fifteen or twenty minutes would sprinkle water at 65° on the sheet. Continued this for two hours, when temperature was 103°; left sheet as it was, and after one hour temperature was 102°. I left the thermometer with nurse, and, after instructing her how to use it, told her to use the water every two hours if the temperature should exceed 103°, and by this

* Read before the New York State Medical Association, Third District Branch, at the annual meeting held June 16 at Elmira, New York.

means we succeeded in keeping the temperature at 103° or less for eight days.

October 19, 8 A.M. Called and found that he had passed a very restless night; had had considerable hemorrhage from the bowels, and had been very delirious; tympanites had increased considerably; pulse 115, temperature 106°; and because of these symptoms the nurse had neglected to use the water since midnight. After looking the case over carefully, I resolved to persist in the use of the cold water, thinking that if I could again reduce the temperature I might yet possibly save my patient. Accordingly I concluded to wrap him in the sheet as before, with water at 65°, and left but little else over him, and told the nurse to sponge his arms and limbs, and every fifteen minutes to wet the sheet with cold water. This we continued for four hours, when temperature was 104°. I then removed the sheet, wiped him dry, and left him for four hours. 4 P.M., temperature 104°; no more hemorrhage from the bowels; pulse 105; sleeping; had used turpentine and opium for bowels. 8 P.M., temperature 104°; used cold water same as before for one hour, when temperature was 103°; left sheet around him, and ordered arms and limbs to be sponged every two hours during the night; gave two grains of quinine every four hours, with tablespoonful of whiskey in glass of milk between.

October 20, 9 A.M. Pulse 95, temperature 102¼°; removed sheet, which was dry now, and ordered sponging to be continued every two hours; other treatment same as before. 6 P.M., temperature 103°; continued same as before.

October 21, 9 A.M. Temperature 102°; no more trouble with bowels; less delirium; pulse 90; tongue beginning to moisten; continued as before, except opium and turpentine. 5 P.M., temperature 102½°; bowels moved twice, no blood; pulse 88; continued as before.

October 22, 11 A.M. Temperature 101½°; one movement of bowels during night; pulse 85; continued quinine and whiskey, and sponging every four hours unless he asked for it oftener, for he had begun to want it: said it made him feel better. 6 P.M., temperature 102°; continued same as before.

October 23, 9 A.M. Temperature 100°, and it did not again exceed that.

I continued the quinine and whiskey for another week, with plenty of milk and beef-tea, at which time I considered the case comparatively out of danger and discontinued my visits. The case went on favorably and made a good recovery.

Case II.—April 6, was called to see J. B., aged 18 years. Had been sick then three weeks, under the care of a neighboring physician.

I found the following symptoms present:

There had been more or less hemorrhage for several days, but for the last few hours it had been more profuse, and with an evacuation which occurred just as I came to the house I should think there was at least half a pint of fresh blood. Tympanites was well marked; pulse 130; temperature 106¼°, with low, muttering delirium when not disturbed; tongue moist, but very red.

I suggested cold water externally, with the use of opium, whiskey, and turpentine internally.

The family, thinking that the patient must die, were willing to try anything; accordingly, a wash-tub half full of ice and water was brought in the room, and, taking two sheets, I folded them so that they would cover the body from the pubes to the breasts. After laying one on the ice until it was cold, I proceeded to cover the whole anterior of the body, and placed the other on the ice. They were changed every fifteen minutes for an hour, and after that every thirty minutes for two hours, when the temperature was 103°. I then ordered them to be changed every hour, and left for four hours. On my return I found temperature 101½°; no hemorrhage; pulse 118; patient sleeping quietly.

I then ordered them to use the water at about the temperature of the room, and change every two hours. Continued opium and whiskey, and also two grains of quinine every four hours.

This was followed closely for one week, except twice for a few hours, when we again used the ice-water, in order to hold the temperature at or about 103°.

At the end of the week temperature was 100°, and did not exceed that again.

Convalescence in this case was slow, yet the patient made a good recovery.

Since that time I have treated several cases in the same way, without losing a single uncomplicated case, and I have seen convalescence well established as early as the eighteenth day. I feel assured that in the majority of these cases, if we can hold the temperature below 102½° or 103°, very little other medicine will be required.

The following conclusions which were given by Dr. Austin Flint, after closely watching the effects of cold water externally in the treatment of seventeen cases of typhoid fever that came under his care in Bellevue Hospital some years ago, are sustained by the results in thirteen cases that occurred in my practice since that time:

1. That by the use of cold water externally in cases of typhoid fever the temperature of the body may, after a variable time of its continuance, be reduced to 102°, or even lower.

2. After a period varying very much in different cases, and also at different times in the same case, the temperature rises as high or higher than before the reduction.

3. Upon repeating the employment of cold as often as the axillary temperature exceeds 103°, the number of repetitions necessary is extremely variable in different cases.

4. The sponge-bath, with the wet sheet and sprinkling, may be employed to the exclusion of the bath-tub in the treatment of typhoid fever.

5. These modes of employing cold water may be continued sufficiently long for the reduction of the temperature to 102°, or even lower, and repeated as often as may be required, without fear of injury. And the study of these cases furnishes no ground for supposing that a liability to complications or accidents is thereby increased; and that the reduction of the temperature by these modes, as often as it rises above 103°, improves the condition of the patient.

6. The results of the analysis of those cases where cold has been faithfully used afford us encouragement to employ it with the expectation of diminishing the severity of the disease and its danger to life.

TRANSLATIONS.

THE CONSTIPATION OF PYREXIA.—Experimental researches of Professor A. Bokai refer the constipation of the bowels which usually accompanies fevers to the effects of the elevated bodily temperature upon the nervous system.

The conclusions drawn from the series of observations are as follows (*Archiv für Experimentelle Pathologie und Pharmakologie*, August, 1887):

1. The reduced amount of nourishment taken by persons sick with fever may favor the occurrence of constipation, but the condition is especially explained by the fact that during the course of the fever the inhibitory nerves of the bowel are in a condition of increased irritability.

2. The exalted irritability of the inhibitory nerves of the bowel during the fever is connected with the increase of the bodily heat, and is a result of it.

3. If the temperature in the rectum, in animals, be raised (by Bernard's apparatus) to 39° C., and not over 42.5° C., the irritability of the inhibitory nerves of the bowel is always evident, and can be reduced by small hypodermic injections of morphine.

4. A bodily temperature going higher than 42.5° C. brings about a paralysis of the inhibitory nerve-fibres of the intestine.

TREATMENT OF SYPHILIS BY HYPODERMIC INJECTIONS OF PHENATE OF SODIUM.—Dr. K. Schadek (*Medicinscoie Obosrenié*, No. 6) reports a new treatment for syphilis. Last year Professor Gamberini proposed to treat syphilitic infection by the double antiseptic, the phenate of mercury. This is a yellowish powder, having a very decided carbolic acid odor, which is obtained by mixing a solution of corrosive sublimate with one of phenate of potassium. This was given by Gamberini in pills of a thirtieth of a grain, of which from two to six were given each day. Drs. Schadek and Troitzki have also used it by injections both subcutaneous and deep.

The injections were not painful, or only slightly so. A two-per-cent. solution in an emulsion of gum arabic was ordinarily used for subcutaneous injections. Dr. Troitzky found that ten injections were sufficient in the majority of cases to cause the syphilitic phenomena to disappear.

In résumé, the author found that the phenate of mercury is superior to all the other mercurial preparations employed by injections. This superiority is due to (1) the rapidity of its action when administered in this form, (2) the absence of any pain or tenderness in the tissues after the injections, and (3) the relative rarity of unfortunate accidents such as stomatitis growing out of the use of the mercurials.—*Bulletin Général de Thérapeutique*, July 30, 1887.

LIGATURE OF THE THYROID ARTERY IN GOITRE.—At the recent German Congress of Surgeons, Dr. Woelfler reported the case of a woman, æt. 45, in whom this operation was done in consequence of an error of diagnosis. The patient came to the clinic with a high grade of dyspnœa, and said that the goitre which was present had been of the same size for years; later it proved itself to be carcinoma. The recovery was without a bad symptom, and the patient left the institution in four weeks. The dyspnœa was gone, and the circumference of the neck was less. In four weeks, however, the difficult breathing returned and the patient came again to the hospital, where a little later she died. On post-mortem examination the author found that the right half of the thyroid gland, in consequence of a necrobiotic process, was notably diminished in size.

PHILADELPHIA
MEDICAL TIMES.

PHILADELPHIA, SEPTEMBER 3, 1887.

EDITORIAL.

THE NINTH INTERNATIONAL MEDICAL CONGRESS.

FROM the time the announcement was first made to the world that the International Medical Congress at Copenhagen had formally accepted the cordial invitation extended by the American Medical Association on behalf of the profession of this country to hold its next meeting at Washington, this journal has never lost faith in the success of that meeting, nor failed to advocate it. As might have been anticipated, it has given rise to some heart-burnings in the profession here, particularly among a certain clique who early tried to monopolize all the offices, but happily the attempt was frustrated; the American Medical Association proved equal to the great emergency, and a proper preliminary organization was effected. By this time the few disaffected ones, who exerted themselves to the utmost in order either to prevent the Congress from meeting in this country at all or to make it a failure by inducing all the prominent European members to remain at home, have probably seen the error of their ways, and are applicants for admission to the Congress which they sought to destroy. Let the cloak of charity be thrown over them, and let them come in: the demonstration of the trifling amount of influence which they were able to exert may afford them a useful object-lesson.

The medical journals, however, which opposed the Congress are in a different position. They abused the trust reposed in them, and deliberately did all in their power to discourage and defeat the efforts of those who were laboring to establish the foundation for a successful meeting. It cannot be expected that they will be allowed to get off so easily. Their offence cannot be readily forgotten nor forgiven. Their publishers can best tell the results of incurring the censure of the profession.

But these questions are not for our guests. We bid them cordial greeting. They shall be met with welcomes wherever they choose to go. Entertainments in New York and Philadelphia have already been given to members on their way to the Congress. During the coming week engagements are announced on the programme as follows: Monday evening, from 8 to 11, conversazione in the large United States Pension Hall at Washington; Tuesday evening, visit to the Corcoran Art Gallery; Wednesday evening, from 8 to 12 o'clock, reception by the citizens of Washington; Thursday evening, from 8 to 11, general reception and buffet banquet at United States Pension Hall; Saturday afternoon, a visit to Mount Vernon. The whole to terminate with an excursion to Niagara Falls.

The scientific papers are numerous and varied, and the indications certainly are in favor of a Congress which shall not be inferior to its predecessors in interest or value.

A MEDICO-LEGAL DECISION AFFECTING LIFE-INSURANCE.

THE insurance companies are frequently found contesting the payment of policies of deceased members, and in a recent case the United States Mutual Accident Association refused to pay a policy where the assured died with malignant pustule. It appeared that the deceased was employed at a place where hides and cattle were received, and that the cause of death was "a putrid animal substance on the exterior of the body working inwardly, and usually communicated from the bodies of animals suffering with diseases of the hair." The policy insured

against death from "external, violent, and accidental means," and excepted death "by taking poison."

The question was whether there could be a recovery under the policy, and the court decided that there could be. The reasoning of the court is interesting, and we quote as follows, at length:

"The word 'poison' therein is used in the ordinary meaning of a substance taken internally, seriously injurious to health, and often fatal to life.

"'Death by poison' is well understood in ordinary language. It is a phrase which would never be applied to death from a rattlesnake-bite, although that injects into the circulation what may be called a poison.

"In certain cases death comes from what is called 'blood-poisoning.' One who dies from a bullet-wound may die of 'blood-poisoning,' but he does not die from poison in the ordinary sense of the word.

"The insured died from what is known as malignant pustule. This is produced invariably, according to the testimony, 'by the infliction of animal substance upon the body,'—by the accidental deposit of this putrid and poisonous animal substance.

"This is usually communicated from the bodies or skins of animals which are suffering with this peculiar kind of disease.

"The substance may be carried by flies that have been feeding on it. The disease may come by the application of the person himself, of his hand, which has been in contact with this substance, to some abraded surface of his body; and the substance may be absorbed by the thin portions of the lips, though they are not abraded.

"The means through which deceased came to his death were external. The positive testimony of the physician shows this. The putrid animal substance reached the body, not through the stomach or lungs, but through the skin, the external covering. The cause was external as much as the crushing under a car or the bite of a rattlesnake would have been."

The gist of the decision is that, in a death of the character mentioned, the deceased could not be said to have "taken poison."

LEADING ARTICLE.

THE GUIDING PRINCIPLES OF TREATMENT IN EXCESSIVE CORPULENCE.

IT must be apparent to every observant physician that cases of excessive corpulence are becoming more frequent in this country. One reason for this greater frequency is probably to be found in the increase in number of persons who live a life of ease, who have no business or occupation to stimulate mind or body to exercise, and who have abundant means to gratify their tastes and inclinations in every particular. Most cases of acquired corpulence will be found in this class after middle age, while the hereditary tendency to excessive fat-production usually manifests itself earlier in life.

The first writer who clearly formulated the causes of corpulence was Brillat-Savarin, the brilliant author of the "Physiologie du Goût." He gives the following as causes of excessive accumulation of fat in human beings: heredity, excess of starchy and saccharine foods, too much sleep, too little exercise, and intemperance in eating and drinking. Although many advances have been made in our knowledge of food-assimilation and metabolism in the last half-century, the shrewd observations of this man of the world upon the nature, causes, prevention, and treatment of corpulence have not been superseded by modern physiological research.

Fat-tissue is formed from each of the three classes of materials which constitute the food of man,—namely, fats, proteids, and carbo-hydrates.

Animal and vegetable fats contained in the food are absorbed by the intestinal mucous membrane. Through the agency of the bile, which moistens the villi and emulsifies the fat, the latter may be taken

up and deposited as fat without first undergoing decomposition in the intestinal canal. Evidence in favor of this form of accumulation of fat has been furnished by Lebedeff and Munk. These observers fed animals upon special fats (such as rape-seed oil), and afterwards demonstrated the special fat used in the feeding experiments in the fat-tissue of the animals.

It is a curious fact that fatty acids may perform the same function in nutrition as the neutral fats. A reconstitution or synthesis of fat from fat acids and glycerin is supposed to take place in the absorbent vessels, thoracic duct, or tissues. The nutritive properties of the fatty acids have even been taken advantage of for therapeutic purposes, and it has been found that equally good results have been obtained from the administration of pure fatty acids, as palmitic and oleic, or their combinations with alkalies, as from the fats,—*e.g.*, cod-liver oil or similar nutrients themselves.

A second source of fat in the body is the decomposition of proteids. It has been shown by a number of investigators that the consumption and assimilation of food containing no fat results, nevertheless, in the formation of fat-tissue and fatty secretions. Thus, the fat contained in milk is largely in excess of the fat taken in with the food. It must therefore necessarily be formed in the body out of non-fatty materials. Carnivorous animals (dogs) deprived of fatty food, and nourished almost exclusively on proteids, yet produced fat. The formation of the higher fatty acids, palmitic and oleic, from decomposing meat-powder freed from fat, has been demonstrated by Salkowski. The process of fatty degeneration of muscular tissue is strong evidence in favor of the conversion of proteids into fat. This evidence is very much strengthened by the circumstance that in acute phosporus-poisoning the rapid fatty degeneration of proteid tissues which takes place in this condition is accompanied by an enormous excretion of urea, showing great destruction of albuminoid tissue.

The production of that curious substance known as adipocere, under certain conditions of albuminoid decomposition not yet well understood, also seems to speak in favor of the derivation of fats from proteids.

Liebig gave the weight of his great authority in favor of the view that the carbo-hydrates are the most fertile, if not the only, source of fat in the body. As pointed out above, the great physiological chemist had been anticipated in this opinion by the gastronomer nearly a quarter of a century.

For many years this view of the principal derivation of fats from carbo-hydrates held sway in physiology, but the experiments of Pettenkofer and Voit seemed to disprove the direct conversion of carbo-hydrates into fats, and it came to be accepted and taught that "no fat is produced directly from the carbo-hydrates consumed."* Recent experiments have, however, shown conclusively that, although the quantity of fat derived from carbo-hydrates is limited, this source of fat-production cannot be excluded. These food-materials have indirectly a large influence in the accumulation of fat by reason of their easy decomposition, which enables them to act as conservators of other food-constituents, which latter may be converted into and deposited as fats. The carbo-hydrates may therefore be principally looked upon as economizing the consumption of proteids and fats.

While it is probable that proteid tissue can only be built up by the proteid substances contained in the food, yet when the food consists exclusively or principally of the latter, the decomposition of proteids in the body is so great that actual loss of proteid tissue results. This has been well shown by an experiment of Rubner. He consumed for several days nearly three pounds of meat per day, but found that, after the second day, the nitrogen excreted in the form of urea exceeded that taken into the body in this enormous quantity of meat. In other words, on an exclusively proteid diet, although excessive, the proteid waste was greater than the income. But the addition of a moderate quantity of fats and carbo-hydrates reduces the proteid waste, and there is consequently a proteid gain. This is an important point to be remembered in combating corpulence by dietetic means.

These facts may be briefly summarized as follows:

Fat-tissue may be derived from (*a*) fats, (*b*) proteids, and (*c*) carbo-hydrates.

Fat consumed with the food is probably the principal source of fat-tissue.

* Landois: Lehrbuch der Physiologie, 2te Aufl., 1881.

The next most prominent source of fat tissue is proteid food-material.

Carbo-hydrates are converted into fat to a limited extent, but are principally useful as oxidizing and conservating foods.

The normal balance between proteid income and expenditure cannot be maintained on proteid food alone. Fat and carbo-hydrates are required to prevent proteid waste.

Bearing these facts in mind, we may proceed to inquire under what circumstances fat is accumulated in excess in the body.

The standard diet for an average man who does a moderate amount of work has been fixed by Voit at one hundred and eighteen grammes proteids, fifty grammes fat, and five hundred grammes carbo-hydrates. Under this diet the balance between income and expenditure, both of nitrogenous and non-nitrogenous constituents of the body, should be maintained. If, however, the individual whom this just suffices to keep in equilibrium were required to perform excessive labor, or any one of the classes of foods were reduced, he would lose weight, and probably strength. If, on the other hand, he would maintain perfect rest, or either the proteids, fats, or carbo-hydrates were increased, he would, other things being equal, accumulate fat. Should the proteids consumed be diminished while the non-nitrogenous foods are increased, an increase of fat with diminution of proteid tissue would result. If excessive, the form of corpulence known as the anæmic is produced. In this form there is progressive diminution of muscular tissue and red blood-corpuscles, and increase of adipose tissue.

It is well known that anæmic individuals are very liable to become corpulent. Chlorosis and corpulence are not infrequent concomitants. Stock-raisers are familiar with the influence of anæmia upon fat-production, and take advantage of it to fatten their stock by frequently bleeding the animals. It is also often seen that persons rapidly become fat after suffering large losses of blood. In the latter case the fat-production is promoted by prolonged confinement to bed.

Too much sleep and too little exercise promote the accumulation of fat, because the excess of fat over that needed for combustion is deposited as fat-tissue. More active exercise would burn up this excess. The experiments of Fisk and Wislicenus and of Frankland have shown that excretion of carbonic acid and the production of heat during work are greater than could be accounted for by decomposition of proteid tissues. Hence it is necessary to assume that an increased destruction of non-nitrogenous constituents of the body takes place during active exercise. Pettenkofer and Voit have shown this by actual experiment, and the latter investigator has estimated that during ten hours of hard work eighty-two grammes more fat are used up in the body than during the same period of rest. The great importance of a knowledge of this fact will become evident on a moment's consideration. It shows that the laborer requires a larger proportion of fatty or carbonaceous food than the idler. Physiologists long regarded the laborer as a foolish fellow when he preferred fat pork to lean beef or chicken for his dinner. Imbued with an erroneous theory which assumed destruction of proteid tissue during work, it was believed that the only method of repairing the proteid waste was to crowd in albuminoid food. The laborer's common sense taught him the true demands of his system long in advance of the physiologist's experiment. The idler and the hod-carrier can maintain their proteid standard on practically the same quantities of nitrogenous food, but the former requires a much smaller proportion of fat and carbo-hydrates. The corollary to be drawn from this is that the easiest way to get rid of an excess of fat is to burn it up by active exercise.

A point of importance to be remembered in this connection is that the amount of fat destructible (oxidizable) by muscular exertion is proportional to the state of muscular development. Hence one of the difficulties of getting rid of an excess of fat in very corpulent individuals by exercise alone lies in the weak muscular development of these individuals.

(To be continued.)

TONSILLITIS.—Let the patient wet his fore-finger and dip it into powdered bicarbonate of sodium. The surface of the tonsil should be rubbed with the end of this finger every five minutes during half an hour, afterwards every hour during the same day. Three applications a day are then sufficient. The author since adopting this treatment has not had to lance a single inflamed tonsil.—*Lyon Médical.*

NOTES FROM SPECIAL CORRESPONDENTS.

PARIS.

KIDNEY Ballottement.—Professor Guyon has indicated a sign that will allow a surgeon to detect an augmentation of the kidney, during its initial period. Hitherto this had not been possible, and, as it is of considerable importance in the early diagnosis of renal complaints, we will state his method. First, as to the method of exploration. M. Guyon remarks that it is usual, in attempting the palpation of the kidney, to get the patient to flex the legs and thighs on the pelvis; but this attitude only seems to make them contract the abdominal muscles, and renders the exploration of the kidney more difficult; so that he finds it preferable to allow the patients to remain quietly in the horizontal position, only taking away the pillows and telling them to breathe slowly and quietly. Then he slips his right hand flat over the posterior region of the kidney, and insinuates the index and medius fingers into the costo-iliac space, and proceeds to raise up this part of the lumbar region by making sharp and repeated pressure. Up to now these shocks have been used to arouse the sensibility of the kidney, which is nearly always manifest in nephritis. However, it is well to commence by searching for pain, as it will be the guide of further exploration. If the pain be severe, the shocks needed to show the *ballottement renal* must be given with great care, so as not to arouse the reflex contraction of muscles, which will interfere with Guyon's sign. The left hand of the operator is now placed flat on the anterior abdominal wall with slight compression, varying according to the case, while the right hand continues the slight shocks until the *ballottement* is felt against the left hand, with something of the same sensation as the abdominal *ballottement* from the fœtus felt in the early months of pregnancy. The pressure of the left hand must not be extreme, because then the kidney will not have room enough, as it were, to move upward and give the sign sought for. When the left kidney is to be examined, owing to its situation, the abdominal hand must be placed higher than on the right side. It must be insinuated under the false ribs a little if possible. This kidney-shock, or *ballottement*, when felt, indicates clearly *an augmentation in the volume of the kidney, and it cannot be obtained when the organ preserves its normal size.*

What is the diagnostic value of this new sign? It is of importance to reveal any slight increase in the size of the kidney *as soon as possible* in all malignant affections of the gland, because its extirpation will be just that much less dangerous and so much more easy as it is least developed. Thus all the kidney-tumors, hydronephroses, renal tuberculosis, and all forms of surgical nephritis will now be better diagnosticated by attempting to get Professor Guyon's sign, and so judging of the slightest augmentation of volume of the kidney, and, as it increases, of the advisability of operation.

Antipyrine.—The application of antipyrine seems to extend day by day. Professor Germain Sée is one of its decided partisans in its use against pain, and goes so far as to count on it in the place of morphine. Its easy solubility allows of its use in subcutaneous injections, and Dr. Sée adopts this form for rheumatic pains in half-gramme doses. It must be stated, however, that at the same time three grammes are given by the mouth, with the result of nearly always calming the pain both in chronic rheumatism and in acute gout.

M. Sée also states that he cured three cases of tic-douloureux, and also cases of painful zona, lumbago, megrim, hepatic colic, nephritic colic, angina pectoris, asthma, and a long list of other troubles, including heart-pains. Professor Sée does not hesitate to conclude that it can entirely replace morphine, and certainly it has not the inconveniences of that drug; but will it always have the fidelity of action that it has against pain? Time alone can tell. At the present moment all the great hospital services are trying antipyrine in all sorts of troubles, so that in a few months its remarkable sedative influence will be investigated enough to enable us to report more fully upon it.

M. Chouppe reports to the Société de Biologie that he had occasion to employ antipyrine in rectal injections to calm uterine colic. In one case a woman was suffering with intense after-birth pains, and an injection containing one gramme of the drug removed the pain. It returned after several hours, but a second injection was given with the result of a definite cure. A second observation was that upon a woman who for several years had violent colic at every menstrual period, which lasted several hours at a time; relief could only be obtained with great difficulty by the use of doses of laudanum or chloral large enough to produce profound sleep. At her last menstrual period, during a most violent attack of pain, one gramme of antipyrine was given by rectal injection, with the result of complete and definite calm being established within a quarter of an hour.

The same author also spoke of the "Reciprocal Action of Antipyrine and Strychnine." He made a number of experiments to see if antipyrine in large doses would modify the form and intensity of strychnine-convulsions, according to a suggestion of Professor Brown-Séquard. He found that the convulsions produced in animals by antipyrine did not at all resemble those of strychnine in three important points: 1st, they were not brought

on by peripheric excitation; 2d, their form was not so tetanic, they consisted of a series of rapid clonic convulsions without any real tetanization of the muscles; 3d, they did not act so much on the muscles of respiration, and this function was not at all suspended with danger of asphyxia, as in strychnine convulsions. Adding the action of strychnine to antipyrine, M. Chouppe injected into the veins of an animal which was already in a state of convulsion from antipyrine a dose of strychnine that should have killed it; but the antipyrine convulsions were simply replaced by strychnine convulsions, and the animal did not die. Then a stronger dose of antipyrine was injected into its veins, which caused the strychnine form to give way to the antipyrine convulsions. The result of various experiments seems to establish that the action of antipyrine to some extent prevents the convulsions of strychnine by reducing the power of the spinal marrow.

Embarras Gastrique.—Professor Peter says he passes a large part of his life talking against bad doctrines and bad medical language, and he considers the above title to be another of the wrong expressions made use of in medicine. Properly, it is intended to express a difficulty in accomplishing a function without any material obstacle,—disordered stomach, in fact; but it almost always is wrongly used, the real trouble being true gastritis. Dr. Peter brings a case before his clinic to prove this fact.

"A young man of 30 years had been examined two years before at a hospital, and the diagnosis given was *embarras gastrique*. This was as false as it often is; for, besides his functional digestive troubles, he had then pain in the epigastric region and slight jaundice, so that it was a real disease, more or less persistent, of the mucous membrane of the stomach, and not a mere disturbance of its function. His history goes to prove this also: he works very hard in a wine-shop, filling bottles, and absorbing the alcoholic vapors, as well as drinking two quarts of wine that he is allowed, not to mention some beer and several doses of bitters, which he takes, so he says, to raise his appetite. His treatment two years ago did him no good, for he continued his habits, with the result that he is now seriously ill. He has cephalalgia, sharp pains in the left hypochondriac region, and extreme prostration with some fever. The digestive difficulty is very marked. We find the spleen very large, with the liver in the same state of congestion, and an impossibility of retaining food of any kind; bleeding from the left nostril exists, and he has petechiæ on his body. So that we have here a patient who is overworked, and indeed poisoned, and all the viscera suffer in consequence. The spleen measures in a vertical direction nineteen centimetres. It is painful upon pressure. This is a fact confirmed by observation in regard to the increase of the spleen in typhoid fever, variola, etc., and in the bad state this man is in he has stored up there in the same way all the products of disintegration. We said that he had 'bleeding from the nose *on the left side*,' and that this fact is a symptom of splenic disease has been handed down to us from Hippocrates, and, passing by Galen, lately our learned friend Professor Verneuil calls our attention to it again. The liver is also increased in size, and the exaggerated increase of the bile-secretion is what Stoll calls 'polycholia:' so that our patient has splenitis and hepatitis, with bilious stools. Our prognosis is very serious.

"What can we do against all these various lesions? In many cases we act through the stomach with our medicines; but here the stomach will not retain anything, let alone drugs, so that we will use revulsion; and you will all testify to the considerable benefit we derive from this therapeutic agency that we have striven for years to insist on the use of, on account of its being so much neglected."

At a later clinic Professor Peter said, "The serious prognosis I gave in regard to the patient you saw last week has happily not been confirmed. I applied at once a large blister to his epigastric region, and the day after his vomiting stopped, so that he could take a little food. Forty-eight hours afterwards a new blister was put on the splenic region, with the result that the pain went away, and to-day the man says he is all right; he has no more pain, and can digest his food. The spleen now measures eleven centimetres instead of nineteen. This man has been in such a low state that I thought at one moment of trying transfusion of blood, and I would have certainly tried subcutaneous injections of ether, which gives such excellent results in serious cases of hemorrhage. But we are relieved of all anxiety by vesication, and I once again, for the thousandth time, call your attention to the marvellous effects of this old remedy of revulsion, which has been allowed to fall into undeserved neglect in these modern days."

Refrigeration of the Healthy Member in Sciatica.—Considerable use is made in France, in the treatment of sciatica, of Professor Debove's method of refrigeration of the line of the painful nerve with chloride of methyl. M. Jacquet now states that immediate cessation of pain can be obtained by refrigeration *of the healthy leg* (!) In ten cases so treated he obtained six cures, which lasted for several days only, however, so that the duration of cessation of pain is much less than by the usual method, and the effect seems to diminish by use. M. Dumontpallier said that these results are in accord with those that he had observed, and he thought he could explain them by admitting that all these actions are produced because the pain has a central ori-

gin. What happens in the case of the sciatic nerve is analogous to what is seen in the stitch in the side in pleurisy and pneumonia, for instance, which will often give way under the influence of a blister *applied on the healthy side.*

M. Ch. Richet said that when one hand was exposed to cold the other one felt in a short time a spasm similar to that felt in the opposite hand. This is a reflex action of the same order, as is well known.

Restoration of the Lower Jaw with the Bone of a Calf.—Professor Richelot read a report of this case at the Société de Chirurgie. It was a young girl of 16, who had been subject to frequent attacks of hysteria, and came to Dr. Richelot for a congenital malformation of the jaws which made mastication almost impossible. The lower jaw was most affected, as its left side was thrown downward and outward, and had a curve much longer than the opposite side, so that proper articulation between the teeth was prevented. On the right side, with the aid of rubber attachment (put on by a dentist), she could triturate slightly some forms of food. Dr. Richelot concluded to make an orthopedic resection of the lower jaw, and on the 25th of July last year he took away, by the aid of Liston's pincers and a perforator, about two centimetres of the bone at the level of the left bicuspid teeth, making a suture with silver wire and exact coaptation of the fragment, adapting the canine-tooth part with the molar portion. This operation was made by the mouth to prevent any exterior cicatrix, but, owing to the insubordination of the patient and the hysterical attacks she was subject to, bony reunion did not take place, and she left the hospital with a pseudarthrosis. Some two months later M. Routier received the girl at the Laennec Hospital, and undertook to cure the pseudarthrosis. At first he thought of using an ivory pin, but after reflection he concluded to use a piece of calf's bone taken from an animal lately killed. The operation was done the 13th of January, 1887, by an incision made on the inferior border of the inferior maxillary, destruction of the fibrous tissue, scraping of the fragments, and introduction of the portion of calf's bone, which secured perfect immobility. The reunion was made without much difficulty, and the bony consolidation followed. The patient was seen the 12th of March last, and was quite well, being even cured of her hysteria, and able to use her jaws quite well, although there is still a slight defect in the articulation of the teeth. M. Richelot added that he was disposed to try putting a slip of animal bone between the fragments in any such resection again, as he saw the perfect consolidation that was obtained after his failure by suture, perforation, and the usual method. The sensibility of the inferior dental nerve was not studied, but there is nothing abnormal at present, and the sensibility of the lips was perfect.

Prophylaxis of Transmissible Diseases.—Dr. Martin, in charge of Professor Graucher's service, makes some good remarks in regard to the above subject. Hygiene, he says, is of the utmost importance, and whether we believe or not in the importance of the *rôle* acted by the micro-organisms in the pathogeny of disease, hygiene can act all the same. It is enough to know that some sort of contagion exists, and that it is transmissible, in order to have good reason to prevent its transmission. Most of us know enough to make a prescription when we see a disease, but perhaps it would be better for us if our clients did as the Chinese, and pay as long as they are kept well. The means to be used to prevent propagation of many affections are three in number,—isolation, disinfection, and official information: there is a fourth, that is vaccination, that is good for a single disease, and there is hope that it may be extended to others. Isolation is certainly of very great importance, and not carried out as it should be. All persons apt to contract the disease must be rigidly kept away from the sick-room, particularly children; those who nurse the patient must be kept from the rest of the family, they must not eat or drink in the sick-room, and they must be careful to wash their hands with antiseptic solutions constantly. All curtains, carpets, and hangings must be taken away from the room, and the bed placed in the middle of it; the windows must be opened twice daily, covering the patient well. The time of isolation varies for different maladies, but in a general way twenty-five days will do for varicella and mumps, forty days for measles, scarlatina, and small-pox. In every case the patient must be well enough to have had a bath before seeing any one socially. *Disinfection* is the second means to be used, and Vallin understands by this the complete destruction of all the emanations from the patient, if they smell or not. The number of chemical products used should be small, and fire with steam be added. Corrosive sublimate in one-one-thousandth solution should be preferred, but it has a number of difficulties: one is, it is dear; another, it looks like water; again, it attacks domestic utensils, and cannot be used in strong solutions. So that carbolic acid is best for general use: owing to its characteristic odor, it will not be taken for anything else. All fæcal matters, urine, vomited matters, etc., should be disinfected at once, and the mixture then placed in a wooden box filled with earth, and not thrown into any stream or the usual closets. When any article used is not of much value, it should be destroyed by fire. Articles of value should be steamed under pressure. If this cannot be done, do not give the linen to the usual washwoman until it has been kept

for a considerable time in a solution of hot antiseptic fluid. Finally, it is the duty of the doctor to inform the city authorities; and while the law does not compel him to do so, except in cases of cholera, pest, or yellow fever, it is held by Professor Brouardel that in doing so we do not give up the rights of the *secret médical*, but we assist the city to use efficacious measures in stamping out the first signs of an epidemic. The law of silence only applies to venereal diseases or those that may be hereditary: so aid your patients by government or city prophylactic measures when you can. Dr. Martin closes by giving a table that sums up some very interesting facts of difference in mortality, births, etc., in countries like England, Germany, and France, where efforts are made to sterilize soil and localities by proper means leading to general and local salubrity and causing a diminution of epidemics. We give a few of the figures (the most striking):

	Births per 1000.	Deaths per 1000.	Excess of births over deaths.	Fecundity of women per 1000.
Germany.....	37.2	25.7	11.5	151
Italy.....	36.9	27.9	9	148
Switzerland....	35.9	25.7	10.2	114
England.....	34.2	19.9	14.3	130
France.....	24.9	22.6	2.2	99

So that while the mortality in France is not elevated, the excess of births over deaths is very small and the fecundity of the women low.

CASES OF SEWER-GAS POISONING. BY DR. HENRY HUN, OF ALBANY.

THE author reported in detail the histories of twenty-nine cases coming under his observation, in which various diseases appeared to have been due to the inhalation of sewer-gas. He thought it probable that the following diseases may result from sewer-gas poisoning: vomiting and purging, separately or combined, general debility, fever, sore throat of a diphtheritic type, neuralgia and perhaps also myelitis of the anterior horns. These conditions are frequently combined. Fever is frequently associated with the other symptoms. There is one group of symptoms which is almost always present, that is, loss of appetite, extreme prostration, and pain in the head. When this occurs as a chronic condition, we are justified in suspecting that the patient is suffering from sewer-gas poisoning.

Israel T. Dana, M.D., of Portland, Maine, reported a case of aneurism of the abdominal aorta cured by rest, restricted diet, and potassium iodide.

DISCUSSION ON HEMORRHAGIC INFARCTION.

At the evening session the discussion on hemorrhagic infarction was, by appointment, opened by Dr. W. W. Welch, of Baltimore.

The author first referred to the different theories which had been advanced to explain the occurrence of hemorrhagic infarctions. These are (1) changes in the walls of the artery obstructed; (2) the increased pressure with which the blood is sent in from the collateral circulation; and (3) a regurgitant flow of blood from the veins. Numerous experiments had been performed by the author, with the assistance of Dr. Mall, of Johns Hopkins University, to determine which of these theories was the correct one. Hemorrhagic infarctions were produced in the intestines of dogs, and the method of experimentation was given in detail. He presented as the result of his studies the following conclusions:

1. The blood which produces hemorrhagic infarctions comes chiefly, if not exclusively, from the collateral vessels.

2. Hemorrhagic infarctions in the intestine cannot take place merely from a reflux of blood from the veins.

3. The blood-pressure is very low in the region where hemorrhagic infarction occurs, in consequence of occlusion of the main artery.

4. A certain degree of force of the collateral circulation is required to produce a hemorrhagic infarction.

5. No positive proof exists that a change in the vascular walls is essential to the production of a hemorrhagic infarction.

6. The hemorrhage occurs by diapedesis.

7. Where hemorrhagic infarction has taken place the large and small veins are widely dilated with blood, and the arteries contain a smaller quantity of blood than normal. There is stasis in many of the veins and capillaries.

Dr. William Osler, of Philadelphia, the conferee, referred to the

CLINICAL ASPECTS OF HEMORRHAGIC INFARCTION.

Among other cases coming under his observation, he reported the following:

J. M., age 20, admitted to the Philadelphia Hospital October 10, 1886. He had never had syphilis, and was a healthy-looking man. He presented a clear history of typhoid fever with a sickness of six weeks two years previously. His present illness began with diarrhœa one week before admission. For two days he had attacks of bleeding at the nose. There was temperature of 102°, with pain in the abdomen. There was no cardiac mur-

mur, and examination of the lungs gave negative results. The splenic dulness was increased. By October 15 the temperature had reached 103°. There was almost constant delirium. There was some diarrhœa. Coldness of the feet appeared, and continued to increase in degree and extended up the leg. The legs became livid, and no pulsation could be detected in the femoral and popliteal vessels. The patient died on the 17th.

It was supposed that there was thrombosis of the iliac veins with gangrene of the legs, which is one of the rare sequences of typhoid fever. At the autopsy it was found that the lower portion of the abdominal aorta and also the two iliac arteries were plugged with thrombi. There was general peritonitis. The right kidney presented a red-brown infarction. There were no ulcerations in the bowel; no endocarditis. The lungs were normal. There was an infarction in the spleen. During life the blood was examined for microbes, but none were found. After death microbes were found in the spleen.

Hemorrhagic infarction of the liver, under ordinary circumstances, is impossible. A. B., a hard drinker, was admitted to the hospital September 27. His illness began in the previous June, with vomiting and swelling of the abdomen. The dropsy steadily increased. He died two days after admission. At the autopsy a large amount of fluid was found in the peritoneal cavity. There was nothing special found in the heart or lungs. The liver was remarkably cirrhotic. Through the right half of the right lobe there were scattered numerous reddish-brown areas. The walls of the portal vein were thickened, and a large brown thrombus occupied the upper portion of its trunk. The branches passing to the right lobe were filled with clots. The hepatic artery and vein were normal. In this case the hemorrhagic infarctions were in all probability due to the cirrhosis of the liver, which had caused more or less obstruction of the branches of the hepatic artery. The only other case of infarction of the liver which the speaker had been able to find was one reported by Recklinghausen.

In the intestine hemorrhagic infarction is met with in two forms: one involving the mucosa, the other affecting the entire gut. The former not infrequently ends in ulcerative necrosis. The latter form of hemorrhagic infarction is not common in man; in the horse it is frequently seen resulting from thrombi formed from verminous aneurisms of the mesenteric and its branches. This is a common cause of the severe and fatal colic so frequently seen in these animals. In conclusion, the speaker referred to the fact that in the lung it was not uncommon to have a vessel blocked without the production of an infarction. An occasional cause of thrombotic infarction is local disease of the pulmonary artery. It sometimes results from the endarteritis induced by beginning tubercular processes.

In the discussion on these papers Dr. Reginald H. Fitz, of Boston, reported a case which in his experience was quite unique. It was that of an elderly man with globular thrombi in the left ventricle. Emboli were transferred to the splenic artery, but at first were not sufficient to completely occlude the artery. The spleen became enlarged, and thrombi formed in the splenic veins, and from this point the thrombus extended into the superior mesenteric vein. As a consequence, hemorrhagic infarction occurred in the intestines.

Second Day.—Morning Session.

BERGEON'S METHOD OF TREATING PHTHISIS. BY DR. E. T. BRUEN, OF PHILADELPHIA.

With reference to the effect of the injections of sulphuretted hydrogen on the bacillus tuberculosis, Bergeon does not claim that their number has been reduced in any considerable proportion of cases. In the treatment of phthisis there are three main indications. The first is to secure some agent which will act upon the cause of the disease. Climate, diet, and hygiene serve to modify the predisposing causes; but if the bacillus be the real cause of the disease, we lack any agent which will destroy it. The second indication is to prevent the destruction of the tissues, for it is found that as the vitality is increased the number of organisms in the sputa is diminished. The third indication is to control special symptoms which present themselves. Since February last I have employed Bergeon's method of treatment in sixty-one cases. Forty-four of these cases have been benefited, but of these only three appeared to regain full health. Two of these were cases of incipient phthisis, with apparent consolidation of the apex of the right lung. In one of these cases the bacillus tuberculosis was not found, though five examinations were made. In the other case the bacillus was found. In these cases the apparent recovery has been associated with a decided increase in weight. He believes, however, that the disease is simply latent. The third case was one of bronchopneumonia. In all the other cases the lesions were more or less advanced, with the presence of cavities and profuse expectoration. In the fifteen cases in which a negative result was obtained, the treatment in some was followed by temporary benefit. The good results have consisted in lessening of the expectoration, diminution of the cough, lowering of the temperature, and suspending of the night-sweats. In most of the cases there was a diminution of from fifteen to twenty beats in the pulse, and a diminution of half a degree in the temperature during the administration of the gas. Even in those cases

which were benefited, and in which the temperature had been brought to normal, there would be, during the progress of the treatment, occasional outbreaks, with a return of the fever and the other symptoms. These, however, disappeared under a continuance of the injections. In order to determine the effect of the treatment on the bacilli, Dr. E. O. Shakespeare made a number of examinations during the progress of the cases. There has been no diminution in the number of the bacilli. It was, however, thought that in those cases where the treatment had been continued for some time, the reaction of the bacilli to the staining-fluid was less marked.

Two cases have died. In one of these an autopsy was made. This case had been under treatment for two months. The walls of the cavity were moderately smooth and firm, but there was no tendency to cicatrization. The results were of a decidedly negative character.

In most of the cases a solution made by the addition of five grains each of sodium sulphide and sodium chloride to a pint and a half of water was the solution employed. In some cases the strength of the solution had been gradually increased, but where no benefit had been obtained from the weak solution the stronger solution did not act with any better results. The quantity of gas employed at each injection has been about one gallon. If there is pain, the strength of the solution may be decreased or a smaller quantity of the gas may be given. At least an hour should be consumed in each administration of the gas. The patient should rest quietly in bed an additional half-hour until the gas has been absorbed. The admission of atmospheric air should be avoided.

In cases of diarrhœa his experience had been unfavorable, except where the gas was given in very small quantities. Chronic peritonitis is a contra-indication to the use of this plan of treatment. In about one case in every ten he had observed the reaction of sulphuretted hydrogen when a paper treated with acetate of lead had been applied to the mouth. This would indicate that a very small amount of the gas reaches the lung, and that the efficiency of the treatment does not depend upon the use of a strong solution. In no case have any injurious results been seen. In some cases where strong solutions were employed, the appetite and strength seemed to be impaired.

Bergeon's method is chiefly valuable in those cases attended with bronchial catarrh. He had had very little good effect in those cases where there was thickening of the lung without much catarrh. The speaker feared that the trouble and detail necessary to the successful application of this method, and the limitations of its power, would cause it to be set aside for other therapeutic measures.

BRITISH MEDICAL ASSOCIATION.

Fifty-Fifth Annual Meeting, at Dublin, August 2–5, 1887.

(Continued from page 779.)

T. GRAINGER STEWART, M.D., Professor of the Practice of Medicine in the University of Edinburgh, read, in the Section on the Practice of Medicine, a paper on

The Incidence of Albuminuria among the Sick.

Supplementing the inquiry as to the incidence of albumen in the presumably healthy, reported to the Royal Society of Edinburgh, the author had made a series of observations on various groups of patients to which he had access as to its occurrence among them. These patients consisted of one hundred and fifty consecutive private patients, one hundred and fifty consecutive cases from the wards of the Royal Infirmary, one hundred consecutive out-patients, fifty cases from the wards of the Hospital for Sick Children, forty cases from a ward devoted mainly to the treatment of cases suffering with alcoholism, fifty patients from the Fever Hospital, and twenty-five cases of women from the Maternity Hospital. In each case the urine was examined with nitric acid, picric acid, and Fehling's solution.

The author then presented a series of tables.

Table I. showed that, among the private patients, thirty-six, or twenty-four per cent., showed albumen; among the in-door patients of the Infirmary, nineteen per cent.; among the sick children, seven, or fourteen per cent.; among the fever cases, thirty-three, or sixty-six per cent.; among the maternity cases, eighteen, or seventy-two per cent.

Table II. dealt with the causes of the incidence of the albuminuria in the one hundred and fifty private cases. Thirteen out of the thirty-six were due to Bright's disease, one febrile, two vascular, three alimentary, two glycosuric, six functional, eight clearly accidental, one probably accidental.

Table III. dealt with the probable causes in the one hundred and fifty in-door Infirmary cases. Seventy-four cases of albuminuria were met with in the wards; twenty-six were from Bright's disease, five febrile cases, sixteen vascular, six alimentary, five nervous, three glycosuric, five accidental cases.

Table IV. dealt with the probable cause in one hundred out-door Infirmary cases. Of nineteen showing albuminuria, eight were from Bright's disease, three as probably Bright's disease, five vascular, one alimentary, one glycosuric, one probably accidental.

Table V. dealt with the cause in the fifty children. Bright's disease occurred in one case out of the seven, probably Bright's disease two, febrile three, nervous one.

Table VI. showed the results obtained as to

the occurrence of albuminuria among fifty fever cases in the Edinburgh Fever Hospital. Of these, eighteen, or thirty-six per cent., showed albumen with nitric acid, and thirty-three, or sixty-six per cent., with picric acid. Taking the thirty-six cases of scarlet fever separately, we find that thirteen, or 34.2 per cent., showed albumen with nitric acid, and twenty-three, or 60.53 per cent., with picric acid.

Table VII. showed the results in forty cases of alcoholism, either acute or chronic, treated in the Royal Infirmary. The specimens were obtained on the morning after their admission. One would naturally expect a large proportion of albuminurics among such patients, and no doubt the percentage is high. Still, we must remember that the class of patients of which this group is composed is most closely related to that of the soldiers,—that is, the conditions of life, such as heavy bodily labor, etc., which in soldiers conduce to make albuminuria frequent are also operative here. Still, the percentage of albuminurics is distinctly higher than it is among the soldiers, and indeed more closely corresponds with the statistics obtained among the in-door Infirmary patients. While, therefore, the albuminuria is probably mainly to be ascribed not to alcohol, but to the conditions of life, the alcohol must be credited with the increase over what we would expect in healthy individuals of the same class. This may be partly a direct effect of the alcohol, but doubtless the indirect influences as regards inferior diet, and bad hygienic conditions, which intemperance involves, are also factors in the case.

The next question is, How are we to explain the albuminuria in these various conditions? He did not attempt to do this until he had gone over the results of experiments made by different observers with the view of clearing up the question. Certain inferences seem to be warranted from the facts just stated:

1. That in health, so in disease, albuminuria is more common than is generally supposed. 2. That it is more common among patients of adult age than among children. 3. That cases of Bright's disease do not account for one-half the cases of albuminuria met with in practice. 4. That they account for more than any other individual cause. 5. That next to them rank the changes in the renal circulation due to cardiac and other maladies, and accidental cases due to the admixture of blood, pus, etc., with the urine. 6. That, so far as this series of observations shows, cyclical, dietetic, and simple persistent albuminurias are rare. 7. That while in Bright's disease, especially the waxy and cirrhotic forms, the quantity of albumen is at first so slight as to be only shown by picric acid, it yet is more abundant than in albuminuria due to other causes. 8. That in the digestive and nervous cases, and those due to high temperature, the quantity is often so small as only to be discovered by picric acid.

We now turn to note the results of his observations as to the occurrence of peptones in the series of cases examined.

Table VIII. shows incidence of peptonuria in the series of cases examined. It thus appears that only four out of one hundred and fifty patients showed this condition. These cases were (1) a case of cirrhotic Bright's disease with gout and dyspepsia, (2) a case of cirrhotic Bright with heart-disease, (3) a case of rupture of the kidney, and (4) a case of acute rheumatism. The urines were all albuminous. Of one hundred and fifty in-door patients at the Infirmary, sixteen gave the reaction. These were a case of dyspepsia, a case of malignant disease of the liver, stomach, lungs, etc., a case of heart-disease, two of phthisis (one of them syphilitic), a case of pleurisy, nine cases of Bright's disease, and a case of acute rheumatism. Except in the case of dyspepsia, all the urines contained albumen as well.

In the Obstetrical Section, John W. Byers, M.D., of Belfast, read a communication entitled

THE PREVENTION OF PUERPERAL FEVER IN PRIVATE PRACTICE.

The paper gave some statistics showing the great mortality from puerperal fever; but the writer said it was impossible to take measures for its prevention until we had clear ideas as to its causation. After he had discussed various views, he gave his reasons for believing that it was blood-poisoning analogous to septicæmia met with in surgical practice. Taking this view, he believed there were three principal sources by which the poison might be introduced into the system of a lying-in woman:

1st. Sewer-gas, as in unhealthy homes.
2d. The nurse.
3d. The accoucheur.

Under the first head he recommended the inspection of a house before the confinement took place, to see if it was in a proper sanitary condition. He gave rules for the guidance of the practitioner and nurse. He advised the strictest cleanliness, thorough washing of the hands in an antiseptic solution (one to one thousand) of perchloride of mercury, few examinations, a proper management of the third stage, the keeping of the patient on her back for a time after confinement, and the use of antiseptic douches.

He drew attention to the cases in which a decomposing blood-clot or placenta might be the source of the disease, but believed that even in these cases the decomposing mass in the uterus only acted as a nidus in which the poison from without found suitable soil.

He discussed the question of how a physician should act with reference to obstetric practice if he came across cases of scarlatina

or foul surgical wounds, and said he believed by bathing, changing the clothes, and strict antiseptic washings he need not fear to attend a confinement. He said if those who attended women in labor would act as if each one were likely to develop septicæmia, they would take thorough antiseptic precautions, and thus such cases would be reduced to a minimum.

The whole essence of the prevention of puerperal fever was—

1st. To prevent the poison entering the system.

2d. To destroy the poison, if it should get into the genital tract of a patient, before it entered her tissues and blood.

Dr. Robert Barnes read a paper on

THE CAUSES, INTERNAL AND EXTERNAL, OF PUERPERAL FEVER.

A clear understanding of the nature and causes of puerperal fever is the natural antecedent of a rational system of prevention. What is puerperal fever? What are its factors and constituents?

There is not one cause, but a plexus of causes. Failure to comprehend this truth is especially conspicuous in the German works. By a short and arbitrary process of synthesis this school formulated the dogma that puerperal fever is puerperal septicæmia, the result of septic infection from the genital canal, thus overlooking important constituent factors. Starting from the state of gestation, we find it especially marked by exalted nervous and vascular tension. An acute process of building up is going on. Parturition puts to the test every tissue, every function. We have three combined sources of altered blood: first, that derived from gestation; second, that arising during labor; third, that arising from the disintegration of the superfluous tissues built up during gestation. Labor completed, a process is started the very reverse of that which prevails in the gravida. The high vascular tension subsides; the tide turns; the blood is invaded by waste stuff which has to be cast out of the body. This is done mainly by the excreting glands: the liver, kidneys, skin, intestines, lungs, are all called upon for active work. They must discharge the waste stuff as fast as it is received into the circulation. If this waste stuff be not duly excreted, it accumulates and forms foyers of poison. Cases of thrombosis and phlegmasia dolens are mainly the expression of the loss of balance of disintegration and elimination.

This is the simplest, the fundamental form of puerperal fever; but it is the compound of three forms of altered blood: 1, the blood of the gravida; 2, the blood of the parturient; 3, the blood of the puerpera. This is purely autogenetic. I call it endosepsis. The conditions arise entirely within the patient's system.

Another group of symptoms which disturb the orderly course of the puerperal state are influences which retard the secretions and excretions, as chills, malarious conditions, errors of diet (among which insufficient diet is one), bad hygienic surroundings, and emotions.

Meteorology controls these secretions largely, and I believe has no little effect on the frequency of puerperal fever. I show here a number of charts. The first gives, according to the Royal Meteorological Transactions, the general temperature and rainfall for thirty years,—1844 to 1874; the second shows the deaths from scarlatina, fevers, erysipelas, and puerperal fevers for the same period; the third shows the total births and deaths for the same period. The second series I have constructed on the same plan. It consists of the history for ten years,—1875 to 1884. The months and weeks of each year are cast together, so that January consists of thirty weeks, corresponding. In the second series we get the curve for the following ten years. The separation of ten years can be compared with the preceding thirty years. The general similarity of the curves is remarkable. It affords strong evidence of the universal prevalence of the causes. The tables exhibited showed the relation of the seasons and atmospheric conditions to fevers, puerperal and others, and illustrated a law which has been widely recognized, that zymotics are most fatal in the winter. This I believe is true. The damp from the cellars, charged it may be with foul water, but noxious in any case, is sure to be sucked up into the house, and seeks by preference the warmest spot. This is the lying-in room, the heat acting as a relative vacuum in the highly-heated and poorly-ventilated room. This source of danger is distinct from the ordinary drains or sewerage of the house: either may act alone, or they may act together, intensifying the danger.

This damp foul air, drawn into the lying-in room, may be contaminated with specific poisons, as of typhoid, scarlatina, or of erysipelas; but the contamination is not necessary to work mischief in the puerpera. This evil, that the lying-in room is chiefly supplied by air from the lower regions in winter, need hardly be felt in summer, as fresh air is brought directly from the outside. Pressure then works against the up-current; pure air is gained, foul air is repelled. [Here the author showed a model house to prevent this suction of foul air.] During the past winter, an unusually inclement one, I have been called to attend an unusual number of cases of chills and fever. I rarely failed to find sufficient cause for the trouble in the sanitation. I would enforce emphatically the old rule to move the patient to another room, preferably the drawing-room, which is generally the healthiest, most airy in the house.

Sewer-gas, if not carrying zymotic germs, may cause fever. The poison, however, must be kept up. Hence the advantage gained from moving the patient out of her surrounding influences.

As to decomposing matter in the genital tract, we should first close the gates against the entry of the enemy by securing firm contraction of the uterus, and prevent the suction-action of the abdomen. The next step is to give ecbolics, as quinia, cinnamon, nux vomica, ergot, and digitalis. Some combination of these medicines should be given in every labor. We should then eject the enemy and prevent the gathering force by washing out the uterus. Uterine irrigation is especially useful in the autogenetic forms in which noxious matter is taken up from the genital tract. It is not frequently necessary in the heterogenetic or zymotic forms.

The women of the laboring classes go through child-bearing more safely than their pampered and delicate sisters. It is because they are not subjected to and enfeebled by excessive cultivation of the emotional and intellectual elements. The daughter of luxury never knows a day's labor till she is taken in labor, while the woman of the working-classes labors every day.

Lactation is evidence of glandular capacity; failure to produce milk, presumptive evidence of glandular incapacity. Fever prevents or diminishes secretion. In such cases, at least, failure to secrete milk is a primary, not a secondary condition. Fever declares itself because the glands cannot do their duty.

From what precedes, it follows that to insure the fullest security to the puerpera, to put her in the best position to go through the transition from the puerperal to the ordinary state, we must do what we can to keep every organ, including the glandular system, in good working order, and to guard against all known agencies which may disturb the healthy action of the organs.

The relations of meteorology to puerperal fever is a point to which I wish to call especial attention. We see by the tables that puerperal fever, like other fevers, prevails most fatally in winter. To what extent can we control the pernicious influences of winter weather? Domestic meteorology is greatly under our control. We must inquire what are the external conditions which favor correction. The excretory force of the lungs is increased in value in the puerpera. Under ordinary conditions in the non-pregnant they gave off watery vapor, carbonic acid, sometimes ammonia and a minute quantity of organic matter. It is certain the capacity of the lungs increases after labor, so it is probable the quantity of carbonic acid exhaled is increased, and certain the exhalations of organic matter increase. The "gravis odor puerperii" is partly due to this increase. In some cases, though verging closely on antisepsis, the lochial discharge is absorbed. In these I have noted a sallow aspect and a degree of febridity, and I have taken this as an indication for irrigating the cavity of the uterus.

To get rid of the excess of aqueous vapors of carbonic acid and organic excreta by the lungs and skin, a constant supply of pure air is required. It must be dry and comparatively rare. There are two principal modes by which gaseous matter including germs or bacteria is carried: 1, by diffusions; 2, by currents of air. Active diffusions are especially valuable so long as they bring nothing noxious to the patient; but if foul matter comes with the air it will tell against the case. Hence the great importance of a supply of pure air and the removal of all impediments to free circulation. I am disposed to believe the most injurious of all meteorological conditions is damp in the form of saturated air, fog and mist. Wind, rain, and sun are the great purifiers of the atmosphere. Movement of the air promotes diffusion, sunshine works chemical changes, and the rain scours or washes away impurities. All of this, of course, is familiar knowledge; but it is not superfluous to ask if it is fairly applied to the regulation of the sick-room. Let us consider how far we may bring the meteorology of the bedroom to the conditions of healthy external meteorology. 1. Let the lying-in chamber face the south. To combat external damp a fire is best in an open fireplace; the open grate serves as a ventilator to carry off impurities. Among the abominations of self-styled sanitary engineers, I feel called upon to denounce heating by hot-water pipes. They are too often effective means for the culture and diffusion of noxious germs. It is possible also to wash the air by air admitted by a Dobin's tube, by a shower of water falling into the tubes.

The modification of the air by chemical agents, with the mechanical addition of vapors and gases possessing medical virtues.

In the early morning hours, between two and four o'clock, is the time when the wind is the lowest and the meteorological conditions the worst. At this time the ventilation of the room should be attended to with greater care than usual.

All precautions resolve themselves into one word,—cleanliness. All antiseptic precautions are but a part of the general scheme.

The meteorological conditions are of primary importance, though far from underestimating other causes.

Whilst protecting the citadel from the foe without, we should take care that mutiny does not break out within.

(To be continued.)

THE MANAGERS OF THE PENNSYLVANIA HOSPITAL gave a reception on August 31 to visiting physicians on their way to attend the International Medical Congress.

NEW REMEDIES AND CLINICAL NOTES.

Immunity by Injection of Chemical Bodies.—Dr. L. C. Wooldridge recently communicated to the Royal Society a method by which he had been able to protect rabbits from anthrax, which is of considerable interest in connection with the general question of the nature of protection in this and other diseases depending on micro-organisms. The method consists in cultivating the anthrax-bacillus in an alkaline solution of a peculiar proteid body which can be obtained from the testis and thymus gland. The growth is not abundant, and after two days at 37° C. it is removed from the culture-fluid by filtration. A small quantity of filtered liquid is injected into the circulation of a rabbit, and the animal can then withstand the inoculation of extremely virulent anthrax blood. The bacillus itself grown in this peculiar culture-fluid has no protective influence: it either kills or it has no effect. The result is extremely curious, for hitherto protection against zymotic disease has been effected by the communication to the animal of a modified form of the disease against which protection is sought. In Dr. Wooldridge's experiments the protection must be produced by some chemical body the product of the activity of the bacillus. The observation belongs to a new order of facts, and appears to fall in with M. Pasteur's theory as to the method in which immunity to hydrophobia is produced by inoculation of the spinal cord of rabid rabbits. Both find some support in Professor Cash's experiments with perchloride of mercury, in which it was shown that after animals had taken a sufficient quantity of the drug they were no longer liable to anthrax.

Corrosive Sublimate in Intra-Uterine Irrigation.—Dr. Braun, from recent observations, has arrived at the following conclusions concerning the use of corrosive sublimate in irrigation of the uterus and vagina: 1. Vaginal or intra-uterine irrigation is frequently followed by absorption of the injected liquid. 2. When this occurs, mercury is quickly detected in the fæces. 3. If the return of the injected liquid be in any way prevented, absorption occurs rapidly. 4. The one in one thousand solution of sublimate should be used only in serious cases, such as tympanites of the uterus, putrefaction of the fœtus in the uterine cavity, or septic puerperal fever. The injection should not occupy more than a minute in the performance, and should be followed by a copious injection of distilled water. 4. The four in one thousand solution should be injected only in cases of expulsion of a macerated fœtus or in endometritis consecutive to the expulsion of the fœtus in premature delivery. 6. This solution may be of service in puerperal endometritis accompanied by a fetid vaginal discharge; in these cases irrigation should be followed by an injection of pure water. 7. Irrigation should be performed only by a medical man. 8. Irrigation with corrosive sublimate should seldom be employed in women suffering from extensive wounds of the vulva, in those who have been taking mercurial preparations, in cases of atony of the uterus, in anæmic women, or in patients suffering with disease of the kidneys.

Acute Chorea treated with Physostigmine.—By administering the remedy subcutaneously, Riess claims that the duration of the disease is shortened to about a fortnight, and that forty out of forty-four cases were treated successfully with physostigmine, the remaining four being of the very severe form.

MISCELLANY.

The American Dermatological Association held its eleventh annual meeting in Baltimore, August 31 and September 1 and 2, at the hall of the Medical and Chirurgical Society of the State of Maryland. Abstracts of the principal papers will be given hereafter.

Cooper Hospital of Camden.—The staff of the new institution consists of—Surgeons, Drs. Dowling Benjamin, O. B. Gross, J. F, Walsh, and E. L. B. Godfrey; Physicians, Drs. J. McCray, D. P. Pancoast, W. A. Davis, and H. Genet Taylor; Resident Physician, Dr. Harry Jarrett; Pathologist, Dr. Joseph H. Wills.

NOTES AND QUERIES.

OBITUARY.

Nathaniel Archer Randolph, M.D., Professor of Hygiene in the University of Pennsylvania, was accidentally drowned while bathing, August 21, at Longport, near Atlantic City, New Jersey. It is believed that death was really due to a heart-affection from which he had been suffering for some years, and that sudden cardiac failure resulted from violent muscular efforts while struggling in the water to escape from being carried out by the undertow. Dr. Randolph was born at Chadd's Ford, in this State, November 7, 1858, and was a graduate of Cornell University and the Medical Department of the University of Pennsylvania. He was a member of the College of Physicians of Philadelphia and of other societies, and had been for a short time one of the editors of the *Medical and Surgical Reporter*. He especially interested himself in the study of nutrition, and had contributed several papers on the relative value of foods.

E. W. Germer, M.D., ex-President of the State Board of Health, died at Erie, August 22, at the age of fifty-six. He was born in Altsbrisach, Baden, Germany, and graduated in medicine at the Vienna University in 1859. During the Baden revolution he was among the insurgents, and was severely wounded. Coming to Erie, he engaged in the practice of medicine. When the smallpox scourge developed in Erie, he was nurse, physician, undertaker, and clergyman. He was appointed on the State Board of Health by Governor Pattison, and was President of that body last year. He was a member of the National Board of Health, and at the last meeting of the State Board was elected to represent Pennsylvania at the International Sanitary Convention at Berlin next month. While on the State Board, he was on the committee which investigated and located the cause of fever-contagions at Plymouth and Pittsburg. It was through his efforts that the grave of General Anthony Wayne was finally located.

OFFICIAL LIST

OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U.S. ARMY FROM JULY 31, 1887, *TO AUGUST* 27, 1887.

COLONEL CHARLES SUTHERLAND, SURGEON.—Leave of absence extended one month. S. O. 174, A. G. O., July 29, 1887.

MAJOR J. C. MCKEE, SURGEON.—Ordered for duty at Watertown Arsenal, Massachusetts. S. O. 181, A. G. O., August 6, 1887.

MAJOR B. E. FRYER, SURGEON.—Relieved from further duty at Fort Lowell, Arizona. S. O. 176, A. G. O., August 1, 1887.

MAJOR HARVEY E. BROWN, SURGEON.—Relieved from duty in Department of Missouri, and ordered to Jackson Barracks, Louisiana, for duty at that post. S. O. 174, A. G. O., July 29, 1887.

MAJOR H. E. BROWN, SURGEON.—Sick-leave extended to August 6, 1887, on account of sickness. S. O. 184, A. G. O., August 10, 1887.

MAJOR P. J. A. CLEARY, SURGEON.—Ordered to Fort McDowell, Arizona Territory, instead of Fort Assiniboine, Montana Territory. S. O. 180, A. G. O., August 5, 1887.

CAPTAIN JOHN M. DICKSON, ASSISTANT-SURGEON.—Died August 8, 1887. (Station, Fort Mason, California.)

CAPTAIN JOHN DE B. W. GARDINER, ASSISTANT-SURGEON.—Granted leave of absence for one year, on surgeon's certificate of disability. S. O. 177, A. G. O., August 2, 1887.

CAPTAIN J. C. MERRILL, ASSISTANT-SURGEON.—Ordered from Fort Klamath, Oregon, to Watervliet Arsenal, New York. S. O. 181, A. G. O., August 6, 1887.

FIRST-LIEUTENANT WILLIAM E. HOPKINS, ASSISTANT-SURGEON.—Ordered from Angel Island, California, to Fort Mason, California. S. O. 184, A. G. O., August 10, 1887.

FIRST-LIEUTENANT C. N. B. MACAULEY, ASSISTANT-SURGEON.—Promoted to be Assistant-Surgeon with the rank of Captain, by operation of law, August 10, 1887.

FIRST-LIEUTENANT J. E. PILCHER, ASSISTANT-SURGEON.—Ordered from Fort Monroe, Virginia, to Fort Wood, New York Harbor. S. O. 180, A. G. O., August 5, 1887.

FIRST-LIEUTENANT C. L. G. ANDERSON, ASSISTANT-SURGEON. (Station, Whipple Barracks, Arizona Territory.)—Ordered to Fort McDowell, Arizona Territory. S. O. 81, Department of Arizona, August 3, 1887.

FIRST-LIEUTENANT WILLIAM N. SUTER, ASSISTANT-SURGEON.—Ordered to return to Washington Barracks, D. C., on the breaking up of the camp at Creedmoor, New York. S. O. 166, Division of the Atlantic, August 10, 1887.

COLONEL J. H. BAXTER, CHIEF MEDICAL PURVEYOR.—Ordered to proceed from Washington, D.C., to New York City, on public business, and on completion thereof to return to this city. Par. 5, S. O. 187, A. G. O., August 13, 1887.

LIEUTENANT-COLONEL JOSEPH C. BAILY, ASSISTANT MEDICAL PURVEYOR. — Granted leave of absence for one month. Par. 10, S. O. 191, A. G. O., August 18, 1887.

MAJOR W. D. WOLVERTON, SURGEON (Washington Barracks, D.C.).—Granted leave of absence for twenty days. Par. 3, S. O. 171, Division of the Atlantic, August 16, 1887.

MAJOR W. S. TREMAINE, SURGEON.—Found incapacitated for active service by an Army Retiring Board, and extension of leave of absence, on account of sickness, still further extended until further orders. Par. 9, S. O. 192, A. G. O., August 19, 1887.

MAJOR JOHN H. BARTHOLF, SURGEON.—Leave of absence extended one month. Par. 7, S. O. 196, A. G. O., August 24, 1887.

CAPTAIN JULIUS H. PATZKI, ASSISTANT-SURGEON. — Granted leave of absence for one month. Par. 15, S. O. 195, A. G. O., August 23, 1887.

CAPTAIN WASHINGTON MATTHEWS, ASSISTANT-SURGEON.—Ordered to proceed to Phœnix, Arizona Territory, on public business, and on completion thereof to return to his proper station, Surgeon-General's Office. Par. 21 S. O. 195, A. G. O., Aug. 23, 1887.

CAPTAIN CHARLES B. BYRNE, ASSISTANT-SURGEON (Washington Barracks, D. C.).—Granted leave of absence for one month, with permission to apply for an extension of one month. Par. 4, S. O. 171, Division of the Atlantic, August 16, 1887.

CAPTAIN BLAIR D. TAYLOR, ASSISTANT-SURGEON.—Granted leave of absence for twenty days, to take effect on or about August 31, 1887. Par. 7, S. O. 193, A. G. O., August 20, 1887.

CAPTAIN GEORGE F. WILSON, ASSISTANT-SURGEON. — Granted leave of absence for fifteen days. S. O. 78, Department of Dakota, August 8, 1887.

FIRST-LIEUTENANT WILLIAM D. DIETZ, ASSISTANT-SURGEON.—Granted leave of absence for two months, with permission to apply for an extension of one month. Par. 7, S. O. 189, A. G. O., August 16, 1887.

FIRST-LIEUTENANT W. D. MCCAW, ASSISTANT-SURGEON.—Relieved from temporary duty at Fort Riley, Kansas, and ordered to his proper station, Fort Leavenworth, Kansas. Par. 3, S. O. 84, Department of Missouri, August 15, 1887.

FIRST-LIEUTENANT E. L. SWIFT, ASSISTANT-SURGEON.—Ordered to report in person to the commanding general, Division of the Pacific, for duty with troops at Round Valley Indian Reservation. Par. 20, S. O. 195, August 23, 1887.

CAPTAIN HENRY JOHNSON, MEDICAL STOREKEEPER.—Ordered, in addition to his present duties, to take charge of the office and perform the duties of Acting Assistant-Medical-Purveyor in New York City, during the temporary absence on leave of Lieutenant-Colonel Joseph C. Baily, Assistant-Medical-Purveyor. Par. 11, S. O. 191, A. G. O., August 18, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U.S. NAVY FOR THE WEEK ENDING AUGUST 20, 1887.

MEDICAL-INSPECTOR S. ROBINSON.—Placed on Retired List.

PASSED ASSISTANT-SURGEON J. E. GARDNER.—Detached from Naval Hospital, Norfolk, Virginia, and ordered to the Fish Commission Steamer "Albatross."

ASSISTANT-SURGEON WILLIAM MARTIN.—Ordered to Naval Hospital, Norfolk, Virginia.

SURGEON W. K. VAN REYPEN.—Appointed Medical Inspector from August 16, 1887.

PASSED ASSISTANT-SURGEON M. H. SIMONS.—Appointed Surgeon from August 16, 1887.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U.S. MARINE HOSPITAL SERVICE FOR THE THREE WEEKS ENDING AUGUST 27, 1887.

LONG, W. H., SURGEON.—Leave extended six days, on account of sickness, August 13, 1887.

FESSENDEN, C. S. D., SURGEON.—Leave extended thirty days, on account of sickness, August 19, 1887.

GODFREY, JOHN, SURGEON.—Granted leave of absence for thirty days, August 17, 1887.

GLENNAN, A. H., PASSED ASSISTANT-SURGEON.—Granted leave of absence for thirty days, August 18, 1887.

MCINTOSH, W. P., ASSISTANT-SURGEON.—Granted leave of absence for twenty-five days, on account of sickness, August 17, 1887.

BAILHACHE, P. H., SURGEON.—Granted leave of absence for thirty days, August 26, 1887.

CARTER, H. R., PASSED ASSISTANT-SURGEON.—Granted leave of absence for twenty-seven days, August 25, 1887.

YEMANS, H. W., PASSED ASSISTANT-SURGEON.—Resignation accepted, to take effect September 30, 1887, and leave of absence extended to that date, August 24, 1887.

NORMAN, SEATON.—Granted leave of absence for six days, on account of sickness, August 27, 1887.

PHILADELPHIA, SEPTEMBER 17, 1887.

ORIGINAL ADDRESS.

ON THE COLLECTIVE INVESTIGATION OF DISEASE.

From the Inaugural Address of the President of the Ninth International Medical Congress,

PROF. NATHAN S. DAVIS, M.D., LL.D.,
Of Chicago.

[At the opening of his address the orator paid a warm tribute to the memory of one who should have filled the place now occupied by the speaker, Professor Austin Flint, M.D., LL.D., of New York, whose untimely death was an irreparable loss to the whole profession of medicine. Dr. Davis then proceeded to speak of the benefits of medical organization, and then took up the subject of the Collective Investigation of Disease, as follows:]

EVERY experienced and intelligent practitioner of the healing art is familiar with the fact that all acute general diseases are influenced in their prevalence and severity by seasons of the year, topographical and other conditions of the earth, meteorological conditions of the atmosphere, and the social condition and habits of the people themselves. The most familiar endemics vary annually in the same localities; while the great epidemics that have for ages broken over the comparatively limited boundaries of their habitats only at intervals of years, and extended their ravages from country to country and receded again to the source from which they apparently originated, differ widely in the different periods of their prevalence. But in studying the essential causes of any one of these general diseases and the laws and conditions under which such causes operate, he soon finds certain factors, essential for the solution of his problems, wanting.

For instance, if he wishes to identify the date of the first attack of epidemic cholera in a given locality, and the character of bowel affections immediately preceding, the ordinary statistics of mortality will give him only the date of death, which may have been from one to seven days later, or it may have been preceded by one or more cases that ended in recovery. If he is anxious to determine the reason why the disease, on entering one community, develops with such rapidity that in a few days its victims are found in every grade of the population and in almost every street, while in another it develops slowly, adhering persistently to particular classes or localities, he may find, in the ordinary meteorological records, the thermometric, barometric, and hygrometric conditions of the atmosphere, with the direction and the velocity of the winds, but he finds nothing regarding those important though variable elements known as ozone and hydrogen peroxide, active oxidizers; or those nitrogenous products called free and albuminoid ammonia. Neither do the sanitary records give the desired information concerning the composition and impregnations of the soil, or of the organic and inorganic emanations that may arise therefrom.

An adequate knowledge of these absent factors relating to the condition of the earth, air, and water over districts large enough to embrace localities subject to invasions of the epidemics and others known to be exempt through a sufficient length of time to cover several periods of prevalence and periods of absence alike, is essential for enabling us to comprehend the causes that make one district amenable to the prevalence of a disease and another not, as well as the marked differences in the severity and mode of progress of the same disease at different periods in the same localities and same classes of the people. The same additional knowledge would also furnish the basis for further sanitary measures of the greatest practical value.

And yet it must be obvious that the cooperation of numbers of medical men directly engaged in the field of general practice with others possessed of more practical facilities for chemical and microscopical research is necessary for successfully prosecuting such coincident and continuous investigations as would be likely to secure the desired results. Only well-trained general practitioners in every locality chosen for observation could observe and record the date of the initial symptoms of acute general diseases coming under their notice, and at stated intervals collate and report them to a central committee. The daily observations concerning the presence and relative proportion of active oxidizers and of nitrogenous organic elements in the atmosphere and the water would require the selection of one or two experts in chemical and microscopical re-

search for each locality, all making their observations coincidently in time and by uniform methods.

There are included in the organized medical associations of each country the men and materials necessary for prosecuting every well-defined line of inquiry; and these associations, by their stated meetings and their facilities for intercommunication and concert of action, present the entire machinery needed, and are only waiting for well-planned and systematic use.

The tendency to make the permanent medical organizations available for prosecuting work in the directions I have indicated has already been manifested to a limited extent, as may be seen in the formation of the Collective Investigation Committee of the British Medical Association and of the International Collective Investigation Committee, organized during the sitting of the Eighth International Congress at Copenhagen.

An earlier movement more fully of the character I have been endeavoring to explain was made by the American Medical Association in 1875, when a standing committee was appointed to establish in a sufficient number of localities regular coincident daily observations and records concerning all appreciable meteorological conditions, including organic and inorganic elements found in the atmosphere, and the date of beginning of acute general diseases, and report the results at each annual meeting of the Association. The Committee made reports embodying facts of interest and permanent value in 1877, in 1879, in 1881, in 1882, and in 1883.* The latter report contains, among other items, a complete tabulated statement of the free and albuminoid ammonia in the atmosphere for every day in the year ending August 31, 1883, as determined for the Committee by Professor J. H. Long in connection with the laboratory of the Chicago Medical College. The Committee is still prosecuting its work with material in hand for a still more important report at an early day. The greatest difficulty encountered has been to enlist a sufficient number of active practitioners in each locality who would faithfully record the desired clinical facts and report the results to the Committee. But this and all other obstacles can be overcome by persevering and well-directed work.

I trust no apology is needed for having embraced this occasion to attract your attention to the very important question how to make all our medical associations more useful in promoting the science of medicine by more complete methods of investigation, especially in directions where the coincident action of several persons in different places is essential for success.

I fully appreciate the great benefit resulting from the simple mingling of large numbers of medical men in social contact, where each is made to hear constantly, whether on the street, in the hotel, or in the assembly-room, new suggestions, new modes of expression, and to observe the physical and mental effects of the various habits and customs of the different peoples, until each one leaves the general gathering with largely increased mental activity and resources, as was so happily expressed by Sir James Paget in his address to the Congress of 1881, in London. And I appreciate in a still higher degree the benefits derived from the preparation and reading of papers by individuals and the discussion of important questions in all our assemblies.

But, for reasons I have already briefly stated, I hope to see added in every permanent general medical society two standing committees: to one should be referred for critical examination every communication claiming to embody a new discovery in either the science or art of medicine, and the other should be charged with the work of devising such lines of investigation for developing additional knowledge as require the co-operation of different individuals, and perhaps societies, and of superintending their efficient execution until crowned with success.

If ten or twenty per cent. of the money paid for initiation and membership dues by the members of each society were appropriated and judiciously expended in the prosecution of such systematic and continuous investigations from year to year, it would accomplish more in advancing medical science directly, and indirectly in benefiting the human race, than ten times that amount would accomplish if expended in any other direction.

* Trans. of the Am. Med. Assoc., vol. xxvi. p. 125; xxviii. p. 153; xxx. pp. 38, 147; xxxii. p. 481; xxxiii. p. 43; Jour. of the Am. Med. Assoc., vol. ii. pp. 85, 169.

For it must be remembered that when money is expended for material objects, even for food, clothing, or medicine, such materials feed, clothe, or relieve but one set of needy individuals, and are themselves consumed; but the expenditure of money and time in such a way as to develop a new fact capable of practical application either in preventing, alleviating, or curing disease, that *fact* does not, like the food or medicine, perish with the using, but it becomes literally imperishable. Neither are its benefits limited to one set of individuals, but it is transmitted with the speed of the lightning over the land and under the sea to every civilized people; and whatever benefits it is capable of conferring are as capable of being applied to a million as to one, and of being repeated with increasing efficiency from generation to generation.

It has been tersely and correctly stated that associated action constitutes the characteristic and predominating power of the age in which we live. It is by associated action that education in its broadest sense, religion, and civilization have been more rapidly diffused among the masses of mankind during the present century than during any other period of the world's history. It is by the association of capital, wielded by the associated intellects of the nineteenth century, that highways of commerce have been opened over the valleys, through the mountains, across the deserts, and on the oceans, over some of which the material productions of the nations are borne by the resistless power of steam, and along others the products of mental action are moved with the speed of electric currents, until both time and space are so far nullified that the most distant nations have become neighbors, and the inhabitants hold daily converse with each other from opposite sides of the globe. Indeed, it is only by means of such of these highways as have been constructed within the memory of him who addresses you that you have been gathered in this hall from the four quarters of the earth, and through which an account of your doings may be daily transmitted to your most distant homes.

I congratulate you on the fact that the profession you represent has taken the lead of all other professions or classes of men in rendering available these grand material achievements of the age for cultivating fraternal relations, developing and interchanging knowledge, and planning concerted action for rendering human life everywhere healthier, happier, and of longer duration.

This is the ninth grand International Congress in regular series within little more than two decades, and let us hope that all its work will not only be done in harmony and good order, but with such results as will add much to the aggregate of human happiness through all the coming generations.

Without trespassing further on your patience, I must ask your forbearance with my own imperfect qualifications and your generous assistance in the discharge of the responsible duties you have devolved upon me.

ORIGINAL COMMUNICATIONS.

THE TREATMENT OF PULMONARY PHTHISIS.

Read before the Medical Society of the State of Pennsylvania, at its Thirty-Eighth Annual Meeting, held at Bedford, Pennsylvania, June 30, 1887,

BY WILLIAM F. WAUGH, A.M., M.D.,
Professor of the Practice of Medicine and of Clinical Medicine in the Medico-Chirurgical College of Philadelphia.

THE present year has been prolific in remedies for the cure of phthisis. The discovery of Koch, revolutionizing our ideas of etiology, has been followed by an endeavor to readjust therapeutics in order to make it harmonize with the new pathology. As might have been expected, the first attempts were crude and fanciful, based on mistaken notions of the true import of the new teaching, showing that the profession had not yet had time to fully mature their ideas so as to make legitimate deductions therefrom. If there be one fact which above all others is taught by history, it is the exceeding slowness of the human mind in grasping a truth and pushing it to its legitimate deductions. We may rest assured that every possible wrong road will be tried before the right one is hit upon.

The most recent of all the new remedies proposed is the hypodermic use of calcium phosphite, the object being to favor the calcification of the tuberculous masses. As the lacto-phosphate of lime is taken up in large quantities from the alimentary canal, there seems little reason for using it hypodermically. No proof had yet been ad-

duced that the ingestion of lime salts hastens calcification. The true value of these agents is in increasing the strength of the cell-wall, preventing hemorrhage, sweating, and other sources of danger and waste, rather than in causing calcification of tubercular deposits.

Two French observers have been testing the power of various agents to delay the progress of tuberculosis artificially produced. Of all the drugs tried, they found none which gave as good results as tannic acid. Rabbits to which this remedy was administered resisted the effects of the disease much longer than animals to whom the tannin had not been given.

The interference with the digestion which tannin causes, the short time for which it can be administered without injury, and its objectionable local effects, render this drug unsuitable for such a chronic disease as phthisis. Still, it is a step in the right direction, aiming to increase the resisting power of the tissues rather than to destroy the bacilli by a germicidal action.

The treatment by hypodermic injections of corrosive sublimate is only mentioned to express the wonder how any physician can be found who is familiar with germicides, and yet believes that the one-fiftieth of a grain of corrosive sublimate injected under the skin at a distance from the lungs can have any influence upon microbes in these organs.

The Russians have still more recently advised the use of aniline. They claim that very dilute solutions of aniline are destructive to the tubercle-bacillus, and that the body can be saturated with aniline to the requisite degree. In this connection, it is well to remember that antifebrine, which has proved remarkably effectual in combating the fever of phthisis, is transformed into aniline in the human body, and if given continuously for a short period imparts a blue coloration to the body, which, however, is but temporary. This remedy deserves a careful trial. The highly poisonous nature of aniline must not be forgotten, and the effects on the general health of saturating the whole system to the extent necessary to destroy the disease-germs could hardly fail to be injurious. Whether the disease or the remedy be the worse remains to be shown.

For several months the French journals have teemed with papers upon the hypodermic use of various remedies suspended in liquid vaseline. Of all the agents tested, those which have given the best results are iodine and carbolic acid. Of the latter, from fifteen to twenty-three grains are injected daily. This enormous dose is said to be borne without inconvenience. The liquid vaseline used as a vehicle is obtained from Baku. It is said that the American petroleum contains no such body, but this I am assured is a mistake. The Russian vaseline, when perfectly pure, has proved the best vehicle yet introduced for hypodermic use; the French physicians having injected over a pound of it beneath the skin of a horse without the least irritation ensuing. As to the value of this method, it appears unlikely that the introduction of these remedies at a distance from the seat of the disease would prove as effective as when applied directly by the atomizer or by intra-pulmonary injection.

It seems singular that this method, which is so popular in France, attracts scarcely a passing notice here.

The germicidal methods are intended for tubercular cases alone, and would be obviously out of place in chronic pneumonia, fibroid lung, etc., which constitute the larger proportion of cases of consumption. The iodine and phenol injections have been found very useful in chronic bronchitis, but in true tuberculosis it is admitted that notwithstanding the general improvement which follows their use the bacilli continue to be found in the sputa.

One of the first attempts to base the treatment of phthisis on the bacillar pathology was that of Cantani. Claiming that there exists an antagonism between decomposition-germs and tubercle-bacilli, he sought to introduce, by atomization, a pure culture of bacterium termo into the air-passages, in the hope that this lusty auxiliary would meet, conquer, and execute capital punishment upon the intruding bacillus, and thus rid the lungs of his presence. Cases are not wanting in which benefit is claimed from this procedure.

The premises from which this method is deduced are far too vague, and contain too much which is yet unproved, to warrant our putting any more faith in the method than what can be based on experience with it. We first assume that phthisis is due to the tubercle-bacilli,—which is true in but a limited proportion of cases, for we may still quote approvingly the sage re-

mark of Felix von Niemeyer, that the greatest danger to a consumptive is that he may become tuberculous. Next, it is not fairly proved that any such antagonism exists between bacterium termo and the tubercle-bacillus. Third, it is highly probable that the bacterium termo is a worse enemy than the microbe it is supposed to antagonize.

In a late number of the *Philadelphia Medical Times* I have recorded a case of accidental infection of the pulmonary tract with the germs of decomposition. The symptoms which resulted were strikingly similar to those of acute phthisis, and up to the present time have resisted every effort to effect a cure.

Taken all in all, we may say that this method, based on the most flimsy interpretation of the modern germ-theory, may be dismissed from serious consideration until its distinguished author has given us better reasons for its adoption than have yet appeared.

But what of the method of Bergeon,—the renowned rectal inflation by carbonic and sulphydric acids?

Introduced by the proprietors of a mineral spring whose waters contained the ingredients mentioned, the method has received the enthusiastic endorsement of the surgical-instrument manufacturers. Under their skilful management, coupled with the wide-spread desire for a remedy for consumption which, by its singularity, seems to give a hope of success such as has never crowned the ordinary methods, this has become popular to the extent of a craze.

It is not wanting in able advocates in the profession. We are informed by hosts of observers that under the use of these gases the patient gains strength, puts on flesh, the night-sweats cease, the fever falls, the cough lessens, the appetite returns, and despair gives way to hope in the patient's mind!

To one who is an experienced observer of consumptive cases, and who has lived long enough to have seen the rise and fall of successive cures, there is an indescribable pathos in these words. Some of you may recollect that when Bennett introduced cod-liver oil he claimed that it checked the sweats, lessened the fever, restored the strength, improved the appetite, etc. We have not forgotten that when the hypophosphites were brought out they were heralded by the same hopeful expressions. And throughout the long list of new remedies the same claims are put forward. Each is an improvement on all that preceded it; each makes a new epoch in the treatment of consumption.

If this be true, if to the results obtainable from all previously-known agents we add the effects claimed by Bennett for cod-liver oil, by Churchill for the phosphites, elevate our patient still higher with Chaulmoogra oil, harden his tissues by tanning them, preserve him with carbolic hypodermics, impregnate the air he breathes with eucalyptol, gorge him like a Strasburg goose by Debove's method, and, finally, inflate him with gas,—if we continue to pile upon him every successive improvement, where will he land? Will his sweat-glands become finally hermetically sealed, his appetite rival that of the Dragon of Wantley, his weight wax greater until he make Fat Bessie envious, and his strength render him a new Hercules? Or will he not rather, in spite of all our efforts, march steadily down to join the innumerable throngs who have preceded him to the consumptive's grave?

We know that there is not a symptom of consumption which cannot be alleviated. We can check the sweats by agaricine, by atropia, by lacto-phosphate of lime, by a dozen other means; we can control diarrhœa by silver, zinc, and bismuth; we can soothe the cough by opiates, relieve the dyspnœa by quebracho, restore the appetite by acids, and, in a word, can successfully cope with every individual symptom. And, in spite of all, the phthisis marches steadily, relentlessly forward. No, gentlemen, the effects of these successive so-called cures for consumption are not cumulative,—they are identical. They differ in their action upon the various symptoms, but nine-tenths of their true effect is upon the patient's mind. The *modus operandi* is as follows. The physician reads that Professor Blank has discovered a cure for consumption whose effects are truly wonderful. Others try the new remedy, and verify the glowing accounts of the discoverer. The doctor catches the enthusiasm: gets the remedy and takes it to his patient, telling of its marvellous virtues. The genuine hope of the physician awakens that of the patient. The effects expected so ardently soon show themselves, and for a while all goes on swimmingly—until the first failure.

Do we ever succeed so well with a remedy after that first failure? How sure we were that oxalate of cerium was a certain remedy for the vomiting of pregnancy until that fatal first failure; since when it has become useless, the patient reading doubt in our own eyes!

But notwithstanding my lack of faith in it, I have given the method of Bergeon a trial; for I hold that there is a grain of truth at the bottom of every popular delusion, and to obtain this grain of truth it may be worth while to winnow away the bushel of chaff.

Three cases of phthisis (tubercular) have been treated under my supervision by the rectal inflations. I am sorry to say that in no case has there been any perceptible improvement. In one case of advanced phthisis the progress of the disease became much more rapid, but I think this would have been the case had no treatment been instituted.

In a case of suppuration of the cervical glands, with ulcers on both legs, but no lung-disease, rectal injections of carbonic acid alone had a surprising effect. This case had resisted all previous efforts, and was rapidly failing until the gas was used. Each injection was followed in the course of an hour by the occurrence of a ravenous appetite; the food was digested, and the patient's improvement was rapid.

In a case of uterine cancer the gas has not shown any such invigorating power.

These few experiments indicate what I believe will be the final dictum on the subject: that the gas will prove useful as a tonic measure and as an anæsthetic in relieving the cough and dyspnœa of phthisis, but that it will not cure a single case of bacillar consumption.

The use of sulphuretted hydrogen appears to be dangerous and unnecessary. Dupont states that Bergeon himself has given it up, concluding that the good effects are due solely to the carbonic acid. Dupont also calls attention to the fact that these good effects are not so marked as those he has described some years since as following the inhalation of carbonic acid mingled with oxygen. Moreover, by this method he administered as much as one hundred and fifty litres of gas each day, whereas by rectal injection not more than six litres can be used. When the sulphuretted hydrogen is omitted, the effect sought is no longer that of a germicide, but simply a tonic and anæsthetic one, as no other power resides in the carbonic acid.

To conclude, I must express my belief that the results of this treatment will not differ much from those alluded to in the remark of an old patient who had been drinking blood. When I asked him how he was affected by it, he answered that it did him a world of good, and would have eventually cured him, but he got too weak to go to the slaughter-house after it.

Though a thorough believer in the modern germ-theory, I look for greater success in prolonging life and rendering it comfortable by carefully preserving the forces, by checking waste, especially from fever, by maintaining the digestion, and by surrounding the patient with suitable climatic and hygienic conditions, than by any patent, ready methods whatever.

REPORT ON RECENT PROGRESS IN GYNÆCOLOGY AND OBSTETRICS.

BY W. H. H. GITHENS, M.D.

RENAL AFFECTIONS, ECLAMPSIA, ETC., OF PREGNANCY AND LABOR.

A. F. A. KING, M.D., of Washington, D.C., in the *American Journal of Obstetrics*, publishes an article giving a novel and reasonable explanation of the causation of the renal disorders and eclampsia complicating pregnancy. The cases he especially considers are those occurring, for the most part, in primiparous women during the latter months of pregnancy, which usually begin with œdematous swelling of the feet, face, and hands, with or without general anasarca, attended by scanty and high-colored albuminous urine, containing renal epithelium, tube-casts, and blood-corpuscles, and which sooner or later may develop headache, gastralgia, nausea, vomiting, derangements of the special senses, and the usual phenomena of uræmia, ending, if not relieved, in eclampsia, premature delivery, etc., and sometimes in death of both child and mother.

Disturbances in the renal circulation and functions are produced chiefly by pressure of the gravid uterus upon the abdominal aorta or its branches, or upon the vena cava or its branches, or all of these, *in consequence of the child and womb not maintaining during pregnancy their normal lateral obliquity above the pelvic brim.*

The normal attitude of the child before labor begins *is the dorso-anterior position of an oblique presentation* (commonly, inexactly, and erroneously termed a "transverse" presentation). A head-presentation, as this expression is usually meant to imply presentation of the head "towards the centre of the canal of the pelvis and os uteri," with the long axis of the child parallel with the axis of the plane of the pelvic brim, is abnormal during pregnancy.

The normal position of the gravid uterus during the latter months of pregnancy, before labor begins, is the lateral oblique, corresponding with the oblique position of the child, the fundus uteri containing the pelvic extremity of the fœtus being usually directed towards the right side of the lumbar vertebræ: this being due to the shape of the organ conforming to the shape of its contents; the os and cervix may still be found, on vaginal examination, with but little or no lateral deviation from the median line.

When the womb and child have risen from the pelvic cavity into the abdominal cavity, they should so remain until the advent of labor. The pelvic canal is chiefly the *channel of exit,* and no part of the child should again enter it until it is ready to go out and be born; while the abdominal cavity above the brim is the *cavern of residence.* These statements apply to primiparæ as well as to multiparæ, and the author joins issue with those "high authorities" who teach that it is normal for the fœtal head in the former to "descend into the pelvic cavity three months before full term," calling this descent the *second* stage in the "mechanism of labor." Can it be that this "second step" *normally* occurs in primiparæ three months before it is time for labor to begin? He believes the oblique presentation, with the lower end of the fœtus resting upon an iliac fossa, to be normal in both.

Just before the end of pregnancy the uterine contractions premonitory of actual labor serve to alter the long axes of womb and child from their oblique position, and bring them sufficiently in line with the axis of the plane of the superior strait to allow the lower end of the fœtal ovoid to slip off the cushioned ledge of the iliac fossa on which it has reposed and commence its descent into the pelvic cavity. This change in the position of the child is probably one of the direct exciting causes of labor.

When the womb and child maintain during pregnancy their normal lateral obliquity, the canal of the cervix, from the external to the internal os, will remain until full term unobliterated, which is the normal condition for both primiparæ and multiparæ.

When the normal obliquity of womb and child is maintained during pregnancy, there will be no injurious compression upon any blood-vessels. So long as the child remains poised obliquely above and across the pelvic brim, certainly nothing below the brim will be compressed; nor will the fundus reach high enough to touch the renal blood-vessels which lie on the second lumbar vertebra. That part of the child and womb in contact with the lower lumbar vertebræ will contain no hard part by which injurious compression of the aorta or iliac arteries could be made; and the head of the child will tend to glide away from the woman's spine, away from the aorta and iliac vessels.

When, on the contrary, the womb and fœtus maintain a vertical position,—that is, with their long axes in line with the axis of the plane of the pelvic brim,—they are continually crowded for space by their abdominal surroundings, and the direction of this crowding is chiefly downwards and backwards towards the lumbar spine and the blood-vessels that lie upon it, finally compelling the lower segment of the womb to descend prematurely into the pelvic cavity.

Dr. King assumes that pressure of the gravid womb upon the aorta, vena cava, and their branches will produce renal disorder. Another factor is compression of the ureters by the gravid womb.

Œdema and venous congestion of the lower extremities is the best evidence of venous obstruction higher up; hemorrhoids, varicose veins, and thrombi of the vulva are additional evidence. Aortic compression would be indicated by tension of the arterial system above the obstruction, as shown by tension of the radial pulse, which is especially pronounced in uræmic cases.

In cases with albuminuria, nephritis, and uræmia, the convulsions occur in the same way as they do in males suffering

from uræmia consequent upon Bright's disease. Cases with but little or no albuminuria or kidney-trouble, but in which albuminuria may be increased by the convulsions, are explicable upon the "uterine irritation" theory of Tyler Smith, who maintained that true puerperal convulsions were produced by centric or peripheral irritation of the spinal system of nerves; pregnancy, labor, or the puerperal state being recognized causes of such an irritation. An abnormal position of the uterus and fœtus, with premature obliteration of the cervix, premature distention of the cervical canal and lower uterine segment, with thinning of its muscular wall and tearing of its decidua, and premature descent of the lower end of the fœtal ovoid below the pelvic brim, are amply sufficient to account for the uterine irritation which Tyler Smith conceived to be the peripheral exciter of convulsions, even when there was but little or no renal disturbance; and in such cases the convulsions would be increased in strength and frequency during labor.

The causes of the abnormal position of the uterus and contents are tight dress, corsets, coitus, and abnormal postures,—resting the hands and forearms above the abdomen, bending forward when standing or walking.

Dr. King has searched very widely through the attainable obstetric records for facts and figures bearing for and against his theory, and has made out a very strong argument in its favor. His method of treatment follows naturally from the supposed cause. In cases of albuminuria or anasarcous limbs or congestive headache the first requisite is to discover and correct any abnormal position of the womb and fœtus, securing a transverse or oblique position of the head above the brim of the pelvis by manipulation or posture, alone or combined, and correcting errors in dress, posture, and habits.

ETIOLOGY, PATHOLOGY, AND CLASSIFICATION OF SALPINGITIS.

In the proceedings of the Gynæcological Society of Chicago, December, 1886, appears a letter from M. Sänger, M.D., of Leipsic, on this subject. There must necessarily be as many forms of pelvic abscess as there are forms of disease of the Fallopian tubes. In the classification given by him (*Archiv f. Gynaek.*, Bd. xxv. pp. 126–33) six different forms are recognized.

The whole sexual tract, from the ring of the hymen to the ostium tubæ abdominale, is open to the entrance of the external air and the germs suspended in it. Carriers of infection coming from the abdominal cavity and its contained organs may also enter at the ostium tubæ abdominale. Even microbes originally lodged in the external parts may, by way of the lymphatics, reach the peritoneal cavity, and thence gain entrance into the tubes.

It has been clearly proved that pathogenous micro-organisms pass from the external parts to the tubes and the peritoneal cavity. These organisms have, in part, been accurately studied, and it is well known that different kinds produce distinct forms of salpingitis, and, secondarily, pelveo-peritonitis. Our present knowledge of the above-mentioned pathogenous micro-organisms will enable us to divide them into three groups:

1st. A.—*Salpingitis gonorrhœica*, produced by the gonococcus of Neisser.

B.—*Salpingitis tuberculosa*, produced by the bacillus tuberculosis of Koch.

C.—*Salpingitis actinomycotica*, produced by the actinomyces bovis of Bollinger.

The gonorrhœal form is most frequently met with. This fact was clinically established by Noeggerath as early as 1872. It is never followed by a destructive suppuration of the uterine appendages; it remains invariably a disease of the surfaces of the mucous and serous membranes. The pus formed by the specifically-diseased mucous membrane gradually distends the tube. In one class of cases the tube is transformed into a large sac, with thin walls; in another, where the muscular tissue of the tube is hypertrophied to a greater extent, the tube becomes much thickened and rigid. In most cases the uterine portion of the tube is thickened, the abdominal end dilated. The serous surfaces become pus-secreting surfaces only where gonorrhœal pus has escaped from the tubes and infected them. He does not believe that gonorrhœal pus ever penetrates the walls of the tubes, and thus produces serous inflammations; but a specific inflammation of the mucous membrane of the tube is accompanied by a non-specific inflammation of the whole tubal wall. This may excite perisalpingitis, etc., and the organs involved may become adherent

to each other; but we never meet with a purulent exudate of the same nature as that found in the cavity of the tube. In some instances gonorrhœal disease of the uterine appendages is accompanied by severe and violent symptoms resembling those of a peritonitis following perforation. In these cases gonorrhœal pus escapes through the ostium abdominale into the peritoneal cavity. In other cases the peritonitis develops insidiously, the peritoneal inflammation being non-specific in character.

Salpingitis tuberculosa has been fully described in Alfred Hegar's lately-published work, "Entstehung, Diagnose und chirurgische Behandlung der Genitaltuberculose des Weibes."

Salpingitis actinomycotica has been described by Adolph Zemann (*Medicin. Jahrbücher der K. K. Gesellsch. der Aerzte in Wien*, 1883, p. 477, Case 4). The tubes in this case were dilated and filled with pus and clumps of the actinomyces.

Group 2d, Salpingitis septica (pyemica, ichorosa, purulenta, diphtheritica).—It simply means that the inflammation is due to infection by a septic virus. The microbes of puerperal septicæmia are identical with those producing traumatic infection in general. During the puerperium the genital tract is far more susceptible to infection than at other times. All suppuration is due to the action of microbes; several varieties have been closely studied, but they are not all known. In this second group the rapidity of the development of the constitutional symptoms and the malignancy of their course may almost entirely obscure the local disturbance of the genital tract.

Group 3d. Forms of infectious salpingitis produced by specific, but as yet unknown, microbes, *Salpingitis syphilitica.* (*Medical Record*, January 24 and February 7, 1885, by Gill Wylie; and Bouchard and Lépine, *Gazette Méd. de Paris*, No. 41, 1866.) We occasionally find in young girls who have never had intercourse with man, tubes filled with pus, and pelveo-peritonitis. These may be tuberculous or gonorrhœal in origin. One case is related in which the tubal disease was consequent on a retro-typhlitis. Certain infectious diseases, like typhoid fever, scarlatina, variola, cholera, also may invade the genital tract.

EXTRA-UTERINE PREGNANCY SUCCESSFULLY TREATED BY ELECTRICITY.

Two cases of extra-uterine pregnancy treated by electricity with a successful result were reported by Dr. Harrison at the meeting of the Obstetrical Society of New York, February 15, 1887. The pregnancies were of about ten and thirteen weeks respectively.

TRUE HERMAPHRODITISM.

At the same meeting Dr. Fowler presented a wax cast of the pelvic organs of a true hermaphrodite who died at the age of twenty-seven years. Ovaries, Fallopian tubes, uterus, penis, and testicles were all present. Menstruation and urination were through the penis.

TRANSLATIONS.

Evolutionary Stages of the Cells of the Stomach.—At a recent meeting of the Paris Biological Society, MM. Pilliet and Trelat described their researches on the different evolutionary stadia of the cells of the cardiac extremity of the stomach. The glandular cells of the cardiac extremity of the stomach are of two kinds. The principal cells are small, cubic, and transparent, and occupy the lower part of the glands; the bordering cells are especially numerous in the centre and neck of the glands. There is a tendency nowadays to consider these two kinds of cells, so distinct in appearance, as different stadia of one element, and the preparations the author described and showed drawings of apparently confirm this view. In the fœtus the inner surface of the stomach is covered with one single kind of cubic cells.

Laskowsky (1868) and E. Brand (1877) stated long ago that in a pig's stomach the differentiation of the two orders of cells is manifest at a much later period (Baginsky 1882, Coudereau 1883). In fish, reptiles, and birds—that is to say, in a large number of species—there exists only one kind of cells in the portion which corresponds physiologically with the cardia of the stomach. These are large and granular. They resemble the bordering cells; nevertheless, have a similar behavior when submitted to the influence of reagents as that of the two kinds of cells found in the upper vertebræ, and consequently constitute a third kind, a mixed kind; their resemblance to the gastric gland has yet to be determined. On a fœtus of a horse of

thirty-five centimetres, the mucosa is raised by large club-shaped folds of areolar connective tissue containing large voluminous capillaries. These folds describe regular villosities and very high ones. The epithelium is composed of prismatic cells ranged in one row; they present a large nucleus and granular protoplasma. There are not any calceiform cells on the surface, nor any differentiated cells at the bottom of the culs-de-sac. The aspect presented is rather that of the intestine than that of the stomach, and this in an animal of considerable size. By an incision made on a level with the lower stomach of a pig's fœtus weighing sixteen centimetres, the peritoneum was found to be composed of fusiform cells closely pressed together; then comes the external muscular layer in the form of a thin covering, of which the lengthened nuclei are of a considerable size as compared with the cellular body. The internal muscular layer is much more developed, and its most inward layer has a tendency to become divided in two; a certain number of its bundles approach the chorion in order to constitute the first rudiments of the mucous muscular layer.

The chorion of the mucous membrane presents irregular conical points; these are separated. The epithelium is composed of cubic cells with large nuclei, occupying almost the whole cell; it is clear, and presents several punctiform nucleoli. These cubic cells, ranged in one row, are limited by a thin cuticle with a double outline. On the stomach of an adult pig, the *pharocothere* treated with alcohol and hæmatoxylin, the evolution of the cells of the gastric gland could be followed through the different stages; it is in the middle of the tubes that the most varied types are to be met with. Each canal is lined with a row of cubic cells with large ovoid nuclei, which present several nucleoli. These cells are pressed against each other, sometimes in a mass in which the cellular outline becomes indistinct. In the centre of the canal is a considerable space. Immediately outside the investment lining of cubic cells and almost continuous with them are the bordering cells, arranged at the periphery and slightly projecting.

But the following fact, which allows of connecting the different cells together, may be observed. A certain number of the principal cells are enclosed in a cytoplasmic granular body, and are intermediary to the cubic cells with hardly any cellular body which are in the centre of the tube, and to the bordering cells which are outside them. All the forms of transition are found here, but it is only in these cells and in the axial cells that ovoid or lengthened nuclei are observed. These cells in developing press back the external wall of the gland, so that each cell, round or oval, provided with lateral expansions fixing it to the wall occupies a little box-shaped enclosure situated on the external side of the glandular tube. It is the series of these small nodosities which gives to the isolated gland its moniliform aspect. In certain places there is most frequently only one cell in each small diverticulum. But sometimes there are several; those at the entrance of the neck of the little enclosure belong to the intermediary stage, and are in continuation with the investment lining of the principal cells. Around each diverticulum are large membranous cells, which compose the connecting cellular lining of the glands. There is no special vascular system, as the capillaries ascend between the glands.

MM. Pilliet's and Trelat's data concerning the formation of the bordering cells very nearly agree with those of Garel (1877), Toldt (1881), Schwale (1878), Ph. Stolz (1882), Kölliker (1882). What becomes of these elements?

These cells present all their characteristic granulations grouped in a special manner round the periphery of the element, leaving a clear space between them and the nucleus. The nuclei in a series of cells, regarded from this point of view, present all the degrees of atrophy up to the complete disappearance of the nucleus. At the same time the granulations of considerable size at the beginning are replaced by much finer grains which absorb the clear space above mentioned and invade the whole cell, which is considerably shrunk. In these small enclosures which contract there are also a certain number of thin granular masses, which gradually disappear. At the same time that this evolution is accomplished inside on a given point in the tube, it also takes place in the whole length of the same tube; the principal cells being considerably more frequent at the bottom of the cuticle sac, and the bordering cells at the neck of the glands. In the pyloric portion, on the

contrary, the glands, more ramified, only present one kind of cells; and in the animal now studied they offer the greatest analogy with the principal cells at the bottom of the glands; those of the neck undergo in part the mucous transformation. In short, the principal cells on these parts may be seen by gradual evolution to resemble the condition of the bordering cells at the same time as they retreat from the axis of the glandular canal; they become atrophied on the spot, but do not then fall into the stomach. (Researches made at the Laboratoire des travaux pratiques de la Faculté.)

Iodol as an Antiseptic Dressing for Wounds and for Internal Use.—M. le Docteur Assaky, Professeur agrégé des Facultés de médecine de France, Professeur de Clinique Chirurgicale à la Faculté de Bucharest, read a paper at the recent International Congress, of which the following are the conclusions:

I. Wounds unite under iodol by first intention. This union, however, being the result of various and complex conditions attending the operation, it is not possible to attribute to iodol alone the absence of suppuration and inflammatory conditions. In wounds which gape and suppurate, iodol is an excellent antiseptic. It retards suppuration, renders the discharges inodorous, reduces the frequency of dressing, and considerably hastens cicatrization. In ulcerating or gangrenous wounds, iodol aids to resist the destructive process, and changes the wound, after a variable time, to a healthy granulating condition. This action of iodol extends also to hard chancres. In case of soft chancres the result is variable. Sometimes it transforms them into a simple granulating wound; at others it is insufficient for this purpose, and it becomes necessary to employ antiseptic lotions in addition.

The same is true with reference to open venereal buboes of the groin. The powdered iodol has this advantage over iodoform, that it is free from odor and is not toxic in its effects.

II. Doses of iodol of from 0.40 centigrammes to two grammes daily produce no functional trouble, even if continued a long time.

These doses give marvellous results in tertiary syphilis and in scrofulous affections. In the secondary stage of syphilis, taken internally, it rapidly destroys the syphilitic manifestations. Iodol seems to aid the general nutrition and increases strength and flesh. It is indicated in all cases of specific malnutrition.

Iodol is an antipyretic. In acute infectious diseases, such as erysipelas, etc., it causes a rapid fall of temperature.

Spermatorrhœa.—Sinety (*Journal de Médecine de Paris*):

℞ Extract of belladonna, 20 centigrammes;
Powdered belladonna, 20 centigrammes;
Confection of roses, q. s. M.
Divide into ten pills.

In nocturnal spermatorrhœa resulting from spasm of the seminal vesicles, the patient must take, at bedtime, from one to three pills, taking the whole dose at once; or he may take five centigrammes of camphor or ten centigrammes of lupulin or one drachm of bromide of potash daily. If, on the contrary, there be atony of the seminal vesicles, injections of cold water and cold douches of ten to twenty seconds' duration are indicated. In addition, morning and evening, ten centigrammes of freshly-powdered ergot and two centigrammes powdered nux vomica are administered. Friction over the lumbar region and internal surface of the thighs with spirits of camphor is beneficial.—*Canadian Practitioner.*

Temperance by "Suggestion."—One of the phenomena which characterize that curious condition known as "hypnotism" is the passive obedience yielded by the subject of experiment to the commands—or, rather, suggestions—of the operator. It is sufficient for the latter to "suggest" that the person under its influence can or cannot do a certain thing, to confer or withdraw the power. This fact is utilized by itinerant showmen for the sake of the irresistibly comic effects to which it can easily be made to give rise. One of the latest applications of this occult power exercised by the mesmerizer over his victim is reported from Soissons, in France, where a local drunkard was inhibited from indulgence in his customary beverages, to the great benefit of himself and the joy of his friends. Possibly the temperance cause may find in hypnotism a valuable ally, but it is probable that the influence of such a salutary suggestion does not last as long as might be desired in the interest of the subject to be reformed.—*British Med. Jour.*

The American Gynæcological Association held its annual meeting in New York during the past week, Dr. A. J. C. Skene, of Brooklyn, presiding. The meeting was of unusual interest from the fact of the presence of a number of foreign visitors who had been attending the International Medical Congress.

PHILADELPHIA
MEDICAL TIMES.

PHILADELPHIA, SEPTEMBER 17, 1887.

EDITORIAL.

ANNOUNCEMENT BY THE PUBLISHERS.

DRS. FRANK WOODBURY and WILLIAM F. WAUGH having purchased the *Philadelphia Medical Times*, it will be continued by them after the present issue.

J. B. LIPPINCOTT COMPANY.

PHILADELPHIA, September 17, 1887.

The J. B. Lippincott Company having transferred to us the ownership and goodwill of this journal, at the beginning of the eighteenth volume, we propose to take advantage of the change to give it a new dress and to introduce other improvements which we think will be acceptable to our readers, while scrupulously maintaining the high standard hitherto established by the publishers. These changes will be referred to more explicitly in the next issue.

FRANK WOODBURY, M.D.,
WILLIAM F. WAUGH, A.M., M.D.,
Editors and Publishers.

THE MEETING OF THE INTERNATIONAL MEDICAL CONGRESS.

IN a note which appeared in the editorial columns of this journal nearly two years ago (October 31, 1885) it was stated that "we believe (1) that a successful and thoroughly creditable meeting of the International Medical Congress will be held in Washington in 1887; (2) that, in spite of malcontents and irreconcilables, existing difficulties will be successfully surmounted under the guidance of Drs. Flint and Davis and the Executive Committee; (3) that a way will be provided for those gentlemen who resigned under a misapprehension to return and accept the offices to which they were originally nominated; (4) that several aspiring Hamlets will be absent when the final cast is made for the play, and they will not be missed."

At the time that those words were penned the prospects for an American International Medical Congress were dark indeed; but our faith did not waver, because it was founded upon the intelligence and patriotic sentiment of the medical profession of this great country. The attempt made by certain men to capture the Congress in the interest of a few Eastern medical schools, and to divide all the offices between themselves and their friends, was, happily, thwarted by the American Medical Association at New Orleans, the members of which emphatically expressed their disapproval of the course taken by men whose prominence in the profession only made their conduct the more reprehensible. To this disagreeable incident we shall not again refer. The Congress is over, and we simply desire to mention the fact that our prediction has been verified. It was not only successful and thoroughly creditable, but it was, according to President Davis, the largest International Medical Congress which has yet been held, if the number be taken of those who came from outside of the city in which its sessions were held. The attendance was so unexpectedly large—there being over two thousand seven hundred names upon the registration-book—that the Entertainment Committee, during the first part of the week, was evidently somewhat embarrassed; but all difficulties were smoothed over later in the week, and every visitor left with the most pleasant impressions of the Congress, and fully satisfied with the work of the Executive and Entertainment Committees.

With regard to the scientific proceedings of the Congress, Sir James Grant

declares that they will compare favorably, in point of number and intrinsic value, with those of any previous meeting of the Congress. Critics who think otherwise will do well to wait until the "Proceedings" have been published; they will appear about the 1st of next year.

One of the novel incidents of the Congress was the publication of a daily edition of the *Medical Register*, of Philadelphia, reporting the proceedings of the eighteen sections and the general session of each day. Such an evidence of American energy, undertaken out of compliment to the Congress, should not be allowed to pass without special mention.

THE PHARMACOLOGY OF SOME BODIES DERIVED FROM MORPHINE.

ONE of the most interesting papers read before the Section on Therapeutics and Materia Medica of the Ninth International Congress was one on the pharmacology of some bodies derived from morphine, by D. B. Dott, F.R.S.E., and Ralph Stockman, M.D., and presented by the latter. The relationship between chemical constitution and physiological action must always be a subject of deep interest to the pharmacologist. In the communication just mentioned the authors discuss briefly the action of a few of the substitution products of morphine as compared with that of the original alkaloid.

How was one of the first chemists who attempted to modify the constitution of alkaloids by acting on them with other bodies. He treated morphine with methyl iodide (CH_3I), and obtained a crystalline body which he named hydriodate of methyl-morphia. This substance he regarded as being formed by the substitution of methyl (CH_3) for one atom of hydrogen (H) in the morphine molecule. In the light of our present chemical knowledge we know that it is not a substitution product, but an addition product, and that the methyl iodide is simply added on to the morphine.

It seems doubtful, indeed, if such bodies are to be considered as morphine compounds. They are more probably new alkaloids. Fraser and Crum Brown examined the physiological action of these morphine bodies, among others, and found that they had a curare-like action. From the nomenclature which they adopt, it is evident that these observers regarded the bodies which they investigated as addition and not as substitution products. Notwithstanding this, we find that in all reference- and text-books which treat of the subject these bodies are spoken of as obtained by substitution, and the opinion is generally held that the substitution of methyl for hydrogen in an alkaloid causes the latter to assume in all cases the action of curare.

There is, however, a great difference both in chemical constitution and physiological action between the addition body ($C_{17}H_{19}NO_3,CH_3I$) and the substitution body $C_{17}H_{18}(CH_3)NO_3$, independently of the iodine contained in the former. As a preliminary, it is necessary to say a few words about morphine itself. It has the formula $C_{17}H_{19}NO_3$, but is better written $C_{17}H_{17}NO.(OH)_2$, containing thus two hydroxyl molecules. It has been repeatedly shown that it is the hydrogen atoms in these hydroxyls which are most easily replaced by such radicals as methyl (CH_3), ethyl (C_2H_5), and acetyl C_2H_3O).

As regards the action of morphine on frogs, two stages, roughly speaking, may be distinguished with doses of thirty to fifty milligrammes. The first stage is characterized by narcosis, the second by tetanus.

In mammalia the second stage is not so easily observed, as the animal generally dies from failure of respiration before its supervention. If artificial respiration be employed, however, the tetanus is permitted to develop fully.

The first body which our authors considered was methyl-morphine, $C_{17}H_{18}(CH_3)NO_3$. It has long been known that codeine prepared from opium had a formula which entitled it to be regarded as methyl-morphine. It was not until 1881, however, that it was prepared artificially from morphine by Grimaux. He showed that methyl-morphine is similar, chemically, to codeine prepared from opium. They prepared this body practically by the same method as Grimaux used, and found that its physiological action is exactly similar to that of codeine as described by Schroeder and others. That is to say, that while in frogs and mammalia it readily induced narcosis, its tendency to cause tetanus was very much greater than that of morphine. It is a much more poisonous substance than the last-named alkaloid, and causes, in a much higher degree, disagreeable symptoms of vomiting and diarrhœa.

Ethyl-morphine, $C_{17}H_{18}(C_2H_5)NO_3$, has exactly the same action as methyl-morphine. It is, therefore, quite immaterial, as regards physiological action, whether the hydrogen atom in morphine be replaced by ethyl or by methyl.

Acetyl-morphine, $C_{17}H_{18}(C_2H_3O)NO_3$, and diacetyl-morphine, $C_{17}H_{17}(C_2H_3O)_2NO_3$, were also examined, and were found to have the same action, qualitatively, as the preceding bodies. They are, however, considerably more powerful, both as narcotics and tetanizers. When administered to dogs, the distress, vomiting, and diarrhœa which were produced were all very extreme.

Dimethyl-morphine was also formed, but at the present time they are hardly in a position to say which H atoms are substituted by the two methyl molecules. Its action differs so entirely from that of diacetyl-morphine that they inferred that different changes had occurred. It was found to be a muscle-poison, resembling saponin somewhat in its mode of action, and to have no narcotic effect, or very little.

From what has been said, it is evident that none of these bodies are to be preferred, clinically, to morphine. With the exception of dimethyl-morphine, they are all more poisonous, and, judged by their action on dogs, possess in a very high degree the tendency to produce nausea and other disagreeable symptoms.

LEADING ARTICLE.

THE GUIDING PRINCIPLES OF TREATMENT IN EXCESSIVE CORPULENCE.

(Continued from page 801.)

A MARKED tendency to overproduction of fat occurs in persons of diminished nervous irritability. Individuals of the so-called "nervous temperament" rarely get fat. On the contrary, those of a phlegmatic type are especially prone to excessive adipose accumulation. Melancholia and "depression of spirits" are not infrequent causes of obesity. This did not escape the acute observation of Shakespeare, who makes Falstaff say,—

"A plague of sighing and grief! it blows up a man like a bladder."

It is probable, however, that in this individual case sack had more to do with Falstaff's fatness than sighing and grief.

The corpulency of alcohol- and beer-drinkers is well known. It is likely that the depression of nervous excitability due to the constant use of alcohol is partly responsible for the fat-accumulation, although the alcohol in ardent spirits, and in the case of beer the carbo-hydrates additionally present, acting as respiratory food, save a portion of the fat in the food from oxidation and permit its deposit as fat-tissue. Although fleshy beer-drinkers are said in popular parlance to be "bloated," meaning by that a defective or inferior kind of fat, there is no evidence that their adipose tissue differs in quality from that produced by other causes.

Many physicians seem to consider corpulence as merely of cosmetic importance to the individual. This is by no means the true state of the case, for the obese subject is exposed to many discomforts

and dangers which his leaner neighbor escapes.

The discomforts of corpulence are sluggishness of movement due to the increased weight of the body, fatigue on slight exertion, hyperidrosis (which is often a troublesome symptom and frequently complicated with intertrigo and eczema), shortness of breath (produced by excessive accumulation of fat in the abdomen and consequent interference with the free motions of the diaphragm), and weakness and rapidity of the pulse. In young women there is often amenorrhœa. The latter is usually a consequence and not a precedent condition of corpulence. Fat married women are frequently sterile, and in both sexes there is depressed sexual desire.

The more dangerous conditions dependent upon or associated with corpulence are fatty accumulation around the heart interfering with its free action, fatty degeneration of the muscular structure of the heart, angina pectoris, chronic endarteritis and its consequences, arterio-sclerosis, and apoplexies which not infrequently result in death. There is often fatty infiltration or degeneration of the voluntary muscles, and of the glandular organs, such as the liver and pancreas. The tendency to the development of diabetes and to the eruption of boils and carbuncles is well known. Some observers, among whom are especially to be mentioned Meckel and Wunderlich, have noticed a pronounced predisposition to cancer in corpulent persons, but this is denied by Kisch. The writer would suggest that sarcoma is much more liable to occur in the corpulent than carcinoma. The former confusion of sarcoma and carcinoma may have given rise to the opinions of Wunderlich and Meckel.

It is an observation as old as Hippocrates that corpulent persons bear febrile diseases badly. The infectious diseases, especially typhoid and pneumonic fevers, give a very unfavorable prognosis in obese patients. The danger may be in great measure ascribed to the difficulty of keeping down the temperature in such individuals. The thick fat-cushion prevents loss of heat by the surface. Active antipyretic treatment is urgently indicated in corpulent fever-patients.

The theory that fat is principally the product of carbo-hydrate food is the basis for most of the methods of treating corpulence by regulation of the diet. The best known of these methods is that prescribed by Dr. W. Harvey for a patient by the name of Banting, who was so pleased with the good results in his case that he afterwards published the details of the method in a pamphlet. The Banting diet consists in a large excess of proteids, and great diminution, almost to extinction from the bill of fare, of fat and carbohydrates. On the theory that proteids alone are muscle-builders, while fats and carbo-hydrates are fat-forming foods, the Banting diet was correct, but the evils of a strict adherence to it were manifest before the recent physiological researches demonstrated the fallacies of the theory. There can be no doubt that Bantingism will reduce excessive fatness, but it also decreases the proteid constituents of the tissues, and may thus cause dangerous and even fatal consequences. It is frequently impossible to arrest the rapid waste of muscular tissue under the Banting diet, and the individual rapidly declines in health, even if the diet is withdrawn and the patient put on liberal allowance. Heart-failure and great general weakness are also quite frequent, and Dr. Fothergill attributes to Bantingism a tendency to the development of lithiasis, with its bad consequences.

On account of the evil results which were frequently noticed as following the strict Banting diet, this has been modified in various ways. Vogel, who introduced the method in Germany, allowed a larger proportion of carbo-hydrates, while Immermann proposes to interrupt the treatment occasionally and allow the patients to resume their habitual diet for a period. On the other hand, Cantani, the eminent Italian clinician, insists even more strongly than Banting upon the rigid exclusion of fats and carbo-hydrates. Beer, spirits, and the stronger wines are restricted or excluded from all dietaries for corpulence. Light acid wines are alone allowed.

In the last five years two new methods, deviating in a rational direction from Bantingism, have attracted the attention of the profession. The first is that of Professor Ebstein, of Göttingen, who proposes a reduction of proteids and carbohydrates and an increase of fat. The philosophical reasoning of Ebstein claims careful consideration, since he bases it upon acknowledged physiological facts. He claims that less fat is deposited if there

is much fat in the food than if the food contained an equivalent quantity of carbohydrates. Practical experience sustains this claim, as well as the further one that a smaller proportion of proteids suffices than is generally assumed. But an important point insisted upon by Ebstein is usually overlooked by his followers: namely, that active muscular exercise assists in the destruction of fats. It is in this single point that Ebstein's method presents the greatest advance over Bantingism.

Oertel's method, which has also many earnest advocates, approaches in its dietetic prescriptions very closely the Banting system, as will be shown presently by a comparison of the different classes of food-materials in the various plans; but an important element in Oertel's regimen is the extremely small quantity of fluids permitted. This is not original with Oertel, as Dancel had already in 1863 insisted upon its importance.

Oertel believes that many of the discomforts of corpulence—to a great degree the corpulence itself—are due to an overfilling of the venous system, and that in consequence the heart is overburdened, the circulation retarded, and tissue-metabolism diminished. In addition, an excessive development of the finer vascular apparatus gives opportunity for the increased accumulation or deposit of fat. Now, by reducing the amount of water or other liquid consumed, the distention of the venous system is relieved,* the heart is allowed to act more forcibly, promoting oxidation and thus consumption of fat-tissue, and areas of small blood-vessels are obliterated, thus limiting new deposit of fat. The deprivation of fluids is also an essential part of the treatment which was successfully recommended by Dr. Schwenninger to Prince Bismarck a few years ago, and which was the occasion of an unfortunate ethical scandal in Berlin. The Schwenninger cure does not differ materially from that recommended by Oertel. Active out-door exercise is also an important part of Oertel's method.

Professor Kisch, of Prague, who is resident physician at the famous sulphate-of-soda springs of Marienbad, has had a very large experience in the treatment of corpulence. He prescribes the waters (which act as a purgative), advises active exercise, and regulates the diet. Doubtless good results follow this treatment, for it is based upon rational principles. The treatment by cold baths and exercise is also successfully applied for the relief of this condition by Winternitz, of Vienna.

Directly contrary to the advice of Oertel to reduce the fluid allowance of corpulent patients, Sée, of Paris, largely increases it. "Let your patients drink,—drink all the time," is the advice he gives. He thinks tea the best beverage, and that it should be consumed in large quantities. This practice is based upon the fact that free drinking of water promotes tissue-metabolism, and hence increases the oxidation of the fat, as pointed out by Landois. The tea renders the water more palatable, and likewise acts as a nervous stimulant.

There is abundant testimony that all these methods are efficient for the reduction of corpulence. In view of the variation of the special dietaries from one another, as well as from the standard diet calculated by the physiologists, there is reason to believe that the effect is not dependent upon the diet alone, but that the collateral regimen, such as the exercise and culture of the skin, has something to do with the result. Voit's standard diet for an average-sized man doing moderate work consists of one hundred and eighteen grammes of proteids, fifty grammes of fat, and five hundred grammes of carbo-hydrates. For comparison, the following calculations of the amounts of the various food-stuffs in the Banting, Ebstein, and Oertel diets are given:

	Banting.	Ebstein.	Oertel.
Proteids.....	170–180 grms.	105 grms.	156–170 grms.
Fats.....	7.5 grms.	60–100 grms.	22–43 grms.
Carbo-hydrates	80–85 grms.	45–50 grms.	71–114 grms.

Landois recommends a gradual and equable reduction of the entire bill of fare, with active exercise in the open air, purgation, cool bathing, stimulation of the skin, restricted hours of sleep, light clothing, and free consumption of liquids. There is reason to believe that such a regimen is more efficient and safer, even if not so rapid in its action, than a plan which depends principally upon the withdrawal of one or other class of food materials.

Regarding the form of exercise to be taken, much latitude may be allowed. Walking, which is the most generally attainable, is efficient and usually agreeable. Horse-back-riding and boating are more ex-

* See an article by Salzer, "The Irritable and the Depressed Heart," *Philadelphia Medical Times*, Nos. 504, 505.

pensive, while bicycling is not devoid of danger to a heavy-weight. Wood-chopping is an excellent means of toning up muscles as well as burning up fat, and the examples of Horace Greeley and Gladstone show that it can be indulged in without loss of dignity.

In prescribing exercise to a corpulent patient, too much should not be expected in the beginning. The muscles have probably long been unused to active contraction, are infiltrated with fat, and rapidly wearied. The new life must be acquired gradually. Early rising, a cold bath, a short but brisk walk, followed by a bath and a spare breakfast, will, if daily repeated, soon drive from the patient his languor and melancholy humor. The after-dinner nap will after a struggle be left off entirely, especially if the dinner be not too abundant or varied. Food should be plain, well cooked, and inviting. It adds nothing to the effectiveness of the treatment if the table has an uninviting appearance. Fats may be used in moderation, but all saccharine substances, beer, ale, or porter, strong wines, and saccharine vegetables should be used very sparingly. They need not be excluded from the diet-list entirely. As a cardiac stimulant a little whiskey and water or a glass of claret, hock, or hard cider may be taken occasionally if needed, although coffee and tea will usually answer the purpose well enough.

The main thing for corpulent persons is, however, active exercise. This, if persistently carried out, will not merely reduce weight, but restore health and strength, which a pure diet-cure often fails to do.

But, after all is said, the management of the individual case must be left to the judgment and discretion of the physician. Corpulent patients differ as widely as temperaments and noses. Some cases will require ferruginous tonics, others cardiac stimulants, still others remedies addressed to prominent complications. Hyperidrosis, eczema, diabetes, dyspnœa, palpitation of the heart, dyspepsias, renal troubles, need attention. In few morbid conditions is careful attention to such details rewarded by better results than in corpulence.

Both the patient and his allowance should be weighed regularly at weekly intervals, in order that the effect of the treatment may be constantly gauged.

GEORGE H. ROHÉ, M.D.

NOTES FROM SPECIAL CORRESPONDENTS.

LONDON.

BACKWARD STATE OF THERAPEUTICS AND PHARMACOLOGY IN THE UNITED KINGDOM—STROPHANTHUS—TREATMENT OF TINNITUS AURIUM—ELECTROLYSIS IN THE TREATMENT OF TUMORS AND STRICTURES—OPERATIVE TREATMENT OF BRONCHIECTASIS—MEN AS NURSES—PATHOLOGICAL DEMONSTRATIONS AT THE DUBLIN MEETING OF THE BRITISH MEDICAL ASSOCIATION—COLOR-BLINDNESS—DEATHS OF M. PASTEUR'S PATIENTS, ETC.

A QUESTION of very great importance for the future of medicine in this country was raised by Dr. Whitla's address as President of the Section of Pharmacology and Therapeutics at the Annual Meeting of the British Medical Association in Dublin. The address was, in fact, an admission that the study of these subjects in this country is in a most unsatisfactory state. Dr. Whitla thinks that what we most want at present is not more new remedies, but a better and more precise knowledge of those already in our hands. However this may be, it is unfortunately true that the work done in this country, whether in the discovery of new remedies or the more complete investigation of old, is very small in amount. The Vivisection Act, which prohibits the performance of experiments upon animals except under restrictions which, in their practical operation, prevent most physicians from making such experiments, is undoubtedly responsible for some of our deficiencies. More weight may be attached to the want of properly-equipped laboratories wherein investigators could work. The general result is that we have grown accustomed to look abroad—to Germany, France, and recently also to America—for nine-tenths of our information with regard to the pharmacology of new and old drugs. But we have not the same excuse for our supineness in the study of therapeutics; and it is upon this fault that Dr. Whitla insisted with much energy. He proposes that the British Medical Association should organize a system by which the experience daily accumulated by hosts of observers should be focussed, sifted, and arranged, and that in particular reports should be invited upon certain chosen drugs. There will be many difficulties in the way of carrying out such a scheme, as Dr. Whitla truly perceives, but his answer to all objections is the paramount importance of the subject and the vital character of the questions or problems to be investigated. There will probably be no lack of volunteers, and the committee which he proposes, if it ever gets to work, might do much good by directing the energies of willing workers into profitable channels. The thera-

peutic literature published in this country is not only small in quantity, but is not, as a general rule, of high excellence. If, that is to say, the term therapeutics may be for a moment limited in meaning, so as to include only the application of drugs to the treatment of disease, no candid observer would accuse us of being behindhand either in surgical methods or in the application of those more general agencies which include the personal hygiene and dietary of the sick. Another proof of the stirring of men's minds in this matter is afforded by the formation of a therapeutical society, which will have its home in London. Dr. Sydney Ringer, F.R.S., has consented to become the first president.

The papers read in the Therapeutic Section after Dr. Whitla's address did not contain many novelties. Dr. Quinlan had a paper on Strophanthus, and exhibited some young growing plants struck by W. T. Christy, the well-known drug-merchant. Dr. Quinlan said that the best thing which strophanthus could accomplish was to strengthen a heart enfeebled by continued pyrexia; in typhoid fever, with a tendency to cardiac failure, he had found it a valuable cardiac tonic. In heart-disease its effect was too transient.

In a discussion on Tinnitus Aurium, in the Otology Subsection, Dr. Woakes, who recommended hydrobromic acid some years ago in pulsating tinnitus, stated that the remedy was only of use in that particular class of cases, and its use indiscriminately for all classes of tinnitus would lead to disappointment. Dr. Lennox Browne referred to the diagnostic value of the observation of Dr. Dundas Grant, that when the tinnitus was due to disease of the middle ear it was diminished by making pressure on the carotid. Dr. Barr believed that hypodermic injections of pilocarpine were of use in certain cases; those, namely, in which the tinnitus was due to recent and minute hemorrhages into the labyrinth. He also spoke highly of Lucal's *Tonbehandlung*. This consists in applying a tuning-fork to the external meatus, sounding a note of an opposite character to the noise heard in the ear. For a hissing noise a low-pitched tuning-fork is used; for a humming or bell note, a high-pitched fork.

Your readers are probably already familiar with Dr. Apostoli's novel and, from a pathological point of view, extremely interesting method of treating fibroid tumors of the uterus by electrolysis. The essential point in it is that he has found it practicable to use very strong currents, going up even to two hundred and fifty milliampères. The internal pole is a platinum sound introduced into the uterus, or a platinum trocar pushed into the substance of the tumor. The external pole is a large mass of wet potter's-earth or modelling-clay enclosed in coarse tarlatan and moulded to the surface of the abdomen; in this way the high resistance which the skin offers to the passage of the electric current is overcome. When the uterine pole is made positive, the result of the passage of the current is to check hemorrhage, and to transform a soft, bleeding surface into a firm and dense membrane; when it is made negative, the result is a dissolution of the contiguous tissues and a profound modification in the nutrition of the diseased tissues.

Dr. W. E. Steavenson, physician-in-charge of the electrical department of St. Bartholomew's Hospital, who has had considerable success in the use of electrolysis, was, I believe, the first in England to take up the method, in conjunction with Mr. Bruce Clarke, for the treatment of urethral stricture. He has now, working with Mr. Walter H. Jessop, applied the method to the treatment of stenosis of the lachrymal duct. A metallic probe was passed through the constricted part of the canal and connected with the negative pole of the battery; the positive pole was placed on the arm. The current used was of the strength of four or five milliampères: it was applied for about thirty seconds at each sitting, with very favorable results.

It should be generally recognized that strong currents must be administered with great care, especially when applied, as in this case, in the neighborhood of the base of the brain: even when every precaution is taken, the patient may suffer from faintness, giddiness, and other unpleasant symptoms.

Professor Grainger Stewart, of Edinburgh, has reported a case of bronchiectasis with very offensive bronchorrhœa in a young man aged 27. The usual remedies having entirely failed, and the stench being so offensive as to render the patient's life intolerable, the aid of surgery was called in. Mr. Caird inserted an aspirator-needle, and obtained a thick, purulent fluid. He then made an incision, resected two ribs, and established free drainage. The immediate result was that the temperature fell, there was a total disappearance of the offensive odor, and the patient's general condition and appearance improved much. The drainage-tube was still *in situ* when the report was made, but the condition of the patient was very much improved.

An interesting paper on male nurses for men was read at the Dublin meeting of the British Medical Association by Surgeon-General C. A. Gordon, C.B., Honorary Physician to Her Majesty the Queen. He advocated the employment of men as nurses for sick members of their own sex, basing his opinions upon extensive experience gained in military hospitals at home and abroad. Women had at various times been employed as nurses in military hospitals, but the practice had always died out. In the French army "manual attendance" by a woman upon a wounded soldier was distinctly prohibited. In the English army nurses have been employed for some

years, and in larger numbers since the Egyptian campaign, and there is an intention to extend the scheme in India. One of the difficulties in that country is that the nurses cannot long stand work in the enervating climate of the plains, and there is no place to send them to. Lady Roberts, the wife of the commander-in-chief, has consequently started a fund for erecting sanatoria in the hills for their use. On active service there are, of course, many other difficulties, but the chief seems to be the question of discipline; the experience when the system was first introduced into Netley was said to have been most unfortunate.

Several very interesting demonstrations were given to the Pathological Section of the British Medical Association at Dublin. Dr. Crookshank, who was recently Professor of Bacteriology at King's College, London, showed a large series of micro-organisms, and demonstrated, I believe, for the first time in this country, some of the peculiar bodies (plasmodium malaria and the semilunar bodies of Laveran) found in malarial blood, and recently so admirably described by Prof. Osler in an address before the Pathological Society of Philadelphia. Dr. Acland and Dr. Skerritt showed specimens of arterio-mycosis. Dr. Sims Woodhead, of Edinburgh, gave a most brilliant demonstration on lung diseases, using large stained sections in a lime-light lantern. Dr. Unna, of Hamburg, gave a demonstration in support of his views with regard to the micro-organisms of leprosy: he holds that the micro-organism is a streptococcothrix and not a bacillus; he believes that so-called bacillus is really a chain of cocci within a double sheath, and that when the bacilli were aggregated together the outer capsules fused together, and so gave rise to the appearance described as "leprosy cells including bacilli." The same physician gave an elaborate demonstration of his method of treating skin diseases with his gelatin-glycerin preparations, plaster-mulls, and salve-mulls. The neatness and cleanliness of these applications are very remarkable, and when we have grown familiar with the method of prescribing the applications they will come into general use.

Dr. T. H. Bickerton read an interesting statistical paper at the Dublin meeting of the British Medical Association on color-blindness with special reference to the examination of sailors belonging to the mercantile marine. He showed the practical importance of the subject to the travelling public, but it will probably be difficult to convince the ship-owners or the Board of Trade to take any further practical steps. Dr. Nettleship suggested that notes should be kept of every accident which could be traced to mistakes in the color of signals made by color-blind seamen and railway-men. This seems to be the most useful suggestion which has yet been made, and if every practitioner within whose knowledge such accidents occur would communicate the particulars to the medical press a mass of evidence might be accumulated which could be used with great effect in future stages of the controversy.

Two patients inoculated by M. Pasteur have recently died in the United Kingdom. The first death was that of a groom, Martin Cahill, aged 29, bitten on the wrist on June 14 by a dog which also bit Lieutenant W. Rushmarsh and two fox-hounds. These two dogs died of rabies. Cahill was admitted into St. George's Hospital, London, on August 11, and died of hydrophobia on August 14. The second death was that of Viscount Doneraile; he as well as his groom was bitten last January by a pet fox subsequently found to be rabid; both Lord Doneraile and his servant went to Paris and were treated at l'Institut Pasteur. Lord Doneraile was taken ill on August 22, and died on August 26; his physician, Dr. Hobart, of Cork, had no doubt that hydrophobia was the cause of death. The groom, who is a young man, remains in good health. The deceased was nearly seventy years of age.

The drought, which has hardly yet come to an end, has been the most severe experienced in these islands since meteorological observations have been accurately recorded. It began in the first week in June, and, though a good deal of rain has fallen since the middle of August, there is still great scarcity of water in many localities. In Manchester water is only supplied for a few hours daily; in Bradford the scarcity is still greater, and in a few country places there is still such an absolute drought that water is sent in milk-cans by rail.

A novel defence was made by some milk-dealers in Dublin charged with supplying the Guardians of the North Union with milk containing 24 to 30 per cent. of added water. It was contended by the contractors that the Guardians got what they contracted for. In the contract it was specified that the milk should have seven and a half degrees, and this, or even more, it yielded, the water notwithstanding. The magistrate refused to convict.

An extensive epidemic of scarlet fever of a mild type prevails at present in London. On August 25 there were seven hundred and forty-five cases of the disease in the hospital of the Metropolitan Asylum's Board. Though the cases are so numerous, the deaths last week were below the average.

DAWSON WILLIAMS.

THE general addresses before the International Medical Congress were valuable contributions to medical literature. Abstracts from them will be given in subsequent issues of this journal.

BALTIMORE.

THE American Dermatological Association held its eleventh annual meeting in this city during the last two days. The attendance of members, as well as the number of papers read, was a little below the average. The character of the work done does not compare very favorably with that done at previous meetings, although some of the papers possessed much merit from a clinical point of view. The discussions were carried on in a lifeless sort of way, and the proceedings as a whole lacked interest.

The social features of the meeting were in striking contrast with the scientific proceedings. The Association had never before met in the South, and the present opportunity was improved by two of the members resident in this city to give a decidedly festive character to the occasion. An elegant reception by Dr. Morison and an enjoyable fête at his country-house by Dr. Atkinson furnished distractions which may be, to some extent, accountable for the meagreness of the scientific results.

Among the guests of the Association was Dr. P. G. Unna, of Hamburg, editor of the *Monatshefte für Praktische Dermatologie*, and one of the most prominent of the younger German dermatologists. Dr. Unna is at present in this country for the purpose of attending the Ninth International Medical Congress, of which he is one of the Vice-Presidents. He entered freely into the discussions before the Association, and his terse, positive, and ready expressions of opinion, evidently based upon exact knowledge, compared very favorably with the hesitating and often vague enunciations of his American brethren. German dermatology has an excellent and well-qualified representative in Dr. Unna. In his informal remarks upon leprosy before the Association he showed profound pathological knowledge, as well as a wide command of therapeutic resources.

In electing Dr. I. E. Atkinson, of this city, as its President, the Association honored one of the original members, who is likewise one of the most modest, energetic, and capable dermatologists in the country. No member in the Association better deserved this recognition.

The "burker" Ross, who was condemned to be hung for murdering a poor white woman and selling her corpse to a medical college in this city, as previously mentioned in this correspondence, was temporarily reprieved last week, pending an investigation into his mental condition. Dr. John Morris, of the State Lunacy Commission, has interested himself in Ross's behalf, and is convinced, after investigation, that the condemned man is weak-minded and not mentally responsible for his actions. His representations induced the Governor to postpone the execution, which had been fixed for last Friday, until he could satisfy himself of the responsibility of the prisoner. He has finally concluded to let the law take its course, and to-day the death-warrant was read to Ross for the second time. If no further interposition of executive clemency occurs, Ross will suffer the death-penalty next Friday.

The Deans of the medical colleges are deeply immersed in correspondence, and I am informed that large classes are expected here during the coming session. G. H. R.

BALTIMORE, September 2, 1887.

PROCEEDINGS OF SOCIETIES.

THE ASSOCIATION OF AMERICAN PHYSICIANS.

(Continued from page 807.)

CLINICAL NOTES ON BERGEON'S METHOD OF TREATING PHTHISIS. BY DR. F. C. SHATTUCK, OF BOSTON.

THE amount of gas contained in the water recommended by Bergeon is only three cubic centimetres, an extremely small quantity. It seemed to him almost impossible that such a small quantity of sulphuretted hydrogen could have any appreciable effect. The solution which Dr. Bruen employed probably contained one hundred and fifty cubic centimetres of sulphuretted hydrogen. Bergeon attributes the good effects to the antiseptic influences of the gas on the suppurative processes. Dr. Trudeau has found that cultures of the bacteria of suppuration and of the bacillus tuberculosis are unaffected by being kept in an atmosphere of sulphurous acid gas. The speaker had treated only seven cases by this method. They were in an advanced stage of the disease. He had seen such improvement follow careful dietetic and hygienic management that he had not much confidence in the results claimed for special methods of treatment in these cases. Any new method of treatment will often have an apparently beneficial effect through its influence on the mind, even in those cases which are incurable. Six of the cases treated suffered with phthisis, and five were in an advanced stage of the disease. One was a case of chronic bronchitis with asthma and emphysema. Four of the patients suffered with more or less pronounced collapse from the use of the injections; nausea, vomiting, and diarrhœa occurred in several cases. In one case, although the patient was weak, no local or general ill effect was observed. In another case the treatment was continued four weeks with no ill effect. The only benefit obtained was a diminution of the expectoration. In the case of asthma and chronic bronchitis thirty-four enemata were given. The improvement was no more rapid than on a previous occasion, when the patient had been treated in the same general way with the

exception of the gas. He presented the following conclusions:

1. Toxic symptoms may follow the injection of sulphuretted hydrogen gas. These are nausea, vomiting, general depression, collapse, and perhaps headache.

2. Strong artificial solutions of sulphuretted hydrogen gas with carbonic acid gas are apt to cause abdominal discomfort. The risk of this is diminished by heating the solution of the former gas.

3. This is not by any means a specific. If useful at all, it is only as an auxiliary to the more usual methods of treatment.

4. The only benefit which we have seen that could be fairly attributed to the enemata was a diminution in the amount of the expectoration.

In conclusion, the author stated that the impression which he had formed was that the good results which had unquestionably followed this method of treatment were attributable in large part to the stimulation induced by the employment of a novel method of treatment which makes the patient feel that something is being done for him.

DISCUSSION.

Dr. William Pepper, of Philadelphia, said that he had, with the assistance of Dr. J. Crozier Griffith, employed this method in a certain number of cases. The injections were given to thirty-four cases, but in ten of them, either on account of the pain induced or for other reasons, the treatment was discontinued. In the remaining twenty-four cases the treatment was continued on an average twenty-five days. Other treatment was frequently combined with the use of the injections. A daily temperature-record was kept in sixteen cases. In four there was more or less reduction; in eleven there was no appreciable effect. In one the temperature increased, but this was probably a coincidence. In no case was the temperature brought from a febrile to a continuously normal condition. The fall was not more than is seen in similar cases under other methods of treatment.

In twenty cases in which the weight was recorded, there was in eight more or less gain. Eight pounds in thirty-seven days was the greatest gain. In six cases the weight remained stationary, and in six it was diminished.

The improvement in cough was not marked. The expectoration was somewhat diminished in four out of twenty-four cases. Search for the bacilli was made in thirty cases, and they were found in twenty-seven. In eleven cases the examination was repeated, and only in four was there any apparent decrease. Cases of night-sweats were not numerous. In one they were checked, and in seven improved. Physical examination showed no improvement in a single case. The enemata had a decided hypnotic influence in three cases. The only unpleasant symptom of any real moment was colic. This was complained of in eleven out of twenty-four cases. Three others suffered so much that the treatment could not be repeated. The colic was not often controlled by giving smaller quantities of the gas, nor did it seem to be influenced by the slowness of the injection. This method of treatment is seldom of real benefit, although it is occasionally of benefit by relieving certain symptoms.

Dr. H. C. Wood, of Philadelphia, after studying the cases treated by this method, had come to the conclusion that it was of a certain amount of benefit. The method of employing the gas presents many objections. The sulphuretted hydrogen should accomplish the same results when absorbed by the stomach as when taken up by the large intestine. He, therefore, had administered the sulphuretted hydrogen gas in carbonic acid water. He regarded this as a distinct addition to pulmonary therapeutics. It is not a new method. In connection with many of the sulphur-springs of Europe there are chambers fitted up where pulmonary catarrh can be treated by inhalation of the gas.

Dr. Beverly Robinson, of New York, had employed this method for the past two months, and his impression is that it is a valuable adjunct to our methods of treatment. The pain which is experienced in many cases may be due to the fact that there are ulcerations in the intestine. These may be present without the existence of diarrhœa. In a case now under treatment, in which tubercular deposits in the lungs are associated with ulceration of the larynx, he thought that this would be a good opportunity to observe the influence of the gas on the local condition. The man has received a daily injection for the past ten days. There has not been the slightest change in the appearance of the larynx.

Dr. George L. Peabody, of New York, said that his results had not been materially better than those of the gentlemen who had preceded him.

Dr. F. Forchheimer, of Cincinnati, had treated thirteen cases with this method. He performed the following experiment. Two or three patients were treated in the way recommended for some time. Then he had substituted for the sulphur solution plain water, and continued the injections for a time. He had also given the carbonic acid gas by injection, and, lastly, he had for two weeks treated these cases with simple injections of air, using the Bergeon apparatus. The patients in these experiments, of course, did not know that any change had been made in the gas employed. As far as he had been able to judge, the patients treated with air did about as well as those treated with sulphuretted hydrogen. It is clear that the introduction of air is not the cause of the pain in the Bergeon method.

Dr. James T. Whittaker, of Cincinnati, said that he had used the sulphuretted hydrogen gas both by injection and also by inhalation. The effects under both methods of administration seem to be the same. It mitigates the cough, relieves the fever, and lessens the night-sweats. It, however, is not a specific.

ATROPHY OF THE GASTRIC TUBULES—ITS RELATION TO PERNICIOUS ANÆMIA. BY DR. F. P. KINNICUTT, OF NEW YORK.

The author gave the histories of two cases in which the typical symptoms of pernicious anæmia were well marked. At the autopsy in each of these cases nothing special was found in any organ but the stomach. The inner surface of the organ was smooth. Microscopical examination was made of numerous sections removed from different parts of the stomach. Throughout a large extent no trace of gastric tubules was found. In some parts the more superficial portions of the tubules could be found, but the deeper portions could nowhere be made out. There was also seen a peculiar hyaline substance in the shape of tubes and of drops. Numerous irregular cells were seen near the surface of the mucosa. The author thought that in this lesion of the stomach was to be found the explanation of a certain number of cases of pernicious anæmia.

In the discussion of Dr. Kinnicutt's paper, Dr. Francis Delafield, of New York, and Dr. William Osler, of Philadelphia, agreed with the author that there is unquestionably a group of cases of pernicious anæmia in which there are serious lesions of the gastric mucous membrane, although these lesions are not always the same.

A THIRD CONTRIBUTION TO THE STUDY OF LOCALIZED CEREBRAL LESIONS. BY DR. E. C. SEGUIN, OF NEW YORK.

The case reported related to the location of the facial centre. The patient, a boy of 7 years, was first seen in January, 1885. He had been complaining of numbness in the right hand. The right leg and arm were slightly paretic. There was no headache and no aphasia. Shortly after this, clonic convulsive movements occurred in the right cheek, and both eyeballs were turned to the right. This lasted for over two hours. At times the speech was thick. There was no history of serious injury, and there was no evidence of pulmonary, renal, or arterial disease. There was no cranial tenderness on pressure. The tongue, when protruded, deviated to the right. The diagnosis was meningeal adhesion over the precentral region. Iodide of potassium was given in gradually-increasing doses until from sixty to seventy-five grains were taken. Early in April of the following year symptoms of tubercular meningitis developed, and the child died after an illness of three weeks. At the autopsy, the ordinary lesions of tubercular meningitis were found. In addition there was a patch of adhesion situated over the left precentral gyrus and the caudal part of the second frontal gyrus. This was one inch in diameter. This would indicate that in the human brain the facial centre is in the caudal end of the second frontal convolution.

The second case related to the situation of the leg-centre. A patient, aged 49 years, suffered with paresis of the right leg and clonic spasm of the right abdominal muscles. There were right hemi-epileptic attacks, the spasm beginning in the abdominal muscles and extending to the arm and leg. These attacks were repeated without loss of consciousness. Paralysis of the right leg and paresis of the right arm developed. There was no aphasia and no choked disk. Attacks of a syncopal character occurred, in one of which the patient died. At the autopsy a large sarcomatous tumor was found, involving the cortex of the paracentral region gyrus. Two small nodules were found in the white substance below the principal tumor. This would indicate that the nerve-centre for the leg was in the paracentral lobule.

DISCUSSION.

Dr. James J. Putnam, of Boston, with reference to the leg-centre, reported a case recently under his care. A man of forty-five, suffering with locomotor ataxia, probably of syphilitic origin, suddenly developed convulsions of the right arm and leg without loss of consciousness, and without change in the voice. The symptoms relating to the arm entirely passed away, but the leg never recovered its normal condition. The patient died some time later, and at the autopsy a small hemorrhage was found at the lower edge of the paracentral lobule.

Dr. F. T. Miles, of Baltimore, also reported a case suffering with Bright's disease, which suddenly became hemiplegic without the voice being affected. The arm and leg were affected. He rapidly improved, but the leg remained weak. He complained a great deal of a dragging in the shoulder. At the autopsy the only lesion that could be found was a hemorrhage of the size of a bean in the paracentral lobule.

Dr. H. M. Lyman, of Chicago, said that some months ago he had seen a case in which there was a sudden convulsion without loss of consciousness, the left arm being principally affected. These convulsions were repeated. There was a paretic condition of the left arm which, in a few days, extended so as to involve the corresponding leg. The convulsive movements of the upper extremity continued to recur. They did not involve the face. The patient died, and a sarcoma was found on the right side, occupying the position of the centres for the arm and leg.

ON THE FREQUENCY WITH WHICH LEAD IS FOUND IN THE URINE—AND ON THE SYMPTOMATOLOGY OF CHRONIC LEAD-POISONING. BY JAMES J. PUTNAM, M.D.

This paper consists of an analysis of eighty-six cases in which the urine had been examined for lead. The analyses were made by Professor E. S. Wood and Dr. A. M. Conny, of Harvard University, although no unequivocal signs of lead-poisoning were present. The cases were divided into the following groups:

	No. of Cases.	Lead Present.	Lead Absent.
1. No symptoms not attributable to other causes	11	2	9
2. Neurasthenia and simple mental depression	9	5	4
3. Fine muscular tremor; nervous debility	9	9	0
4. Multiple neuritis; neuritis with chronic myelitis; spastic paraplegia; multiple sclerosis	19	15	4
5. Locomotor ataxia	3	0	3
6. Progressive muscular atrophy	4	0	4
7. Acute poliomyelitis of the adult	1	0	1
8. Cerebral and cerebro-spinal cases	7	6	1
9. Epilepsy	8	3	5
10. Sciatica	2	0	2
11. Vague neuralgias of long stand'g	4	4	0
12. Profound anæmia	3	1	2
13. Unclassified	6	3	3

The number of cases in these groups is too small to be of statistical value, but may help in the further analysis of the cases, and as a basis for further research. Of the eighty-six cases of which the urine was examined, lead was found in forty-eight and was absent in thirty-eight, and there is good reason for believing that the number of cases in which it was found in the urine does not fully represent the whole number in which it was present in the body.

If from the forty-eight cases in which lead was found we subtract those where the patients were known to have been strongly exposed by their occupation or otherwise, we have left thirty-two, to be contrasted with thirty-eight, as approximately representing the ordinary exposure of the community.

It is to be remembered, however, that the patients were drawn mainly from the poorer classes of the community, and that some of them came from country towns or villages where the practice of pumping drinking-water through lead pipes from a distant well—the end of the pipe resting in the well—is still very common. All such cases that were known were, however, excluded. Taking the evidence furnished by the cases themselves, and seeking to endorse it by testimony drawn from the literature of the subject, by the effects of treatment, we arrive at the following conclusions, which are, of course, only to be regarded as provisional:

1. It is probable that lead may cause neurasthenic symptoms which may exist for a long time without other signs of poisoning.

2. The same is true of fine muscular tremor, especially if associated with debility.

3. The most important conclusion is: lead seems to cause occasionally a greater or less degree of the symptoms classed as spastic paraplegia, instead of the usual type of paralysis with atrophy and loss of the deep reflexes.

4. Additional evidence is furnished of the importance of suspecting lead as a cause of vague cerebral symptoms, such as are often due to syphilis.

5. In one case of epilepsy in a person not predisposed, and where the probable first attack occurred at the age of twenty-five, besides the discovery of lead in the urine there was a slight weakness and impairment of electrical reaction of the long extensors of the fingers.

Two cases of ataxia with extensive muscular atrophy and other signs of peripheral neuritis were reported, probably due to lead.

The next paper read was by I. E. Atkinson, M.D., of Baltimore, entitled

FORMS OF TYPHOID FEVER SIMULATING REMITTENT MALARIAL FEVER.

Continued fever simulating remittent fever is often observed, in malarial localities especially, and is often regarded as such or as typho-malarial fever. While it is now generally recognized that the latter title does not designate a specific integral disease, every one admits the frequent concurrence of the two principles. The term is unfortunate as misleading and encouraging lax habits of observation and treatment. The tendency to attribute the later evolution of frank typhoid symptoms from what at first appeared to be a malarial fever to a transmutation of the latter disease to the former, is of course unjustifiable. The theory that typho-malarial fever or continued malarial fever is a combination of a septic and malarial poison, as defended by Loomis and others, is rejected for the reason that the term "sepsis" is used too indefinitely, and cannot explain facts in the course, history, and pathology of the affection, which, however, may be perfectly reconciled with a typhoid origin. It is apparent that the term "typho-malarial" is made to include many groups of atypical cases.

The object of the present paper is to describe forms of typhoid fever in which all the usually characteristic symptoms are absent except mild fever. These cases commonly occur during the late summer and early autumn. They begin with a chill or insidiously, and assume a course of mild remittent type, never passing into a typhoid condition, never developing the characteristic symptoms of typhoid, yet absolutely uninfluenced by antiperiodic treatment. They last three, four, or even five weeks, and almost always end in slow lysis and recovery. They resemble malarial conditions except in the persistence of the fever under strongly anti-malarial treatment, and in the occasional concurrence of

circumstances pointing to a typhoid origin. There is no hebetude, the patient sleeps well, the tongue is slightly coated, there is almost never epistaxis, constipation is commonly observed, there are no bloody stools, no tympanites, no iliac tenderness or gurgling, and rose spots are usually absent. The patient is bright and cheerful. The more severe cases, after beginning as remittents, may gradually evolve typhoid symptoms. Three cases were reported, showing the type of fever described occurring under conditions indicating their typhoid origin. While typhoid fever is one of the most characteristic of diseases, its special symptoms are very inconstant. There is not a sufficient realization of the mildness with which it often runs its course. Walking typhoid, although usually considered rare, is in reality frequent. Cases in which sudden accidents reveal their true nature are probably but a small portion of the whole number. Our views of typhoid fever have been largely modified. Low ranges of temperature are now often encountered. Straube and Fraentzel and others have reported severe forms of the disease with high mortality, although the temperature did not attain 102.2°. Normal, and even subnormal, temperatures are sometimes maintained throughout the attack. In mild cases a slight degree of fever-heat is not at all uncommon. Liebermeister and others report such cases. Loomis treats "mild typhoid" with walking cases, and states that the eruption appears early and is scanty and brief, and that diarrhœa is present in most cases. This is true of many cases; but there is a large class in which constipation is the rule and rose spots the exception, much larger than is generally admitted. Liebermeister and others describe interesting examples. Dr. W. W. Johnston has most accurately described similar cases occurring in Washington. Malaria often complicates typhoid fever, but it oftener happens that its presence is assumed unjustifiably. A mental bias in favor of malaria is often strongly pronounced in the face of the strongest contrary evidence. The diagnosis of these cases from remittent malarial fever often rests upon the crucial test of treatment. It is admitted that occasionally antiperiodic remedies fail to control the malarial paroxysm, especially in pernicious and adynamic forms. In milder forms the behavior under quinine practically solves the difficulty. Where the full administration of the antiperiodic remedy for a number of days fails to terminate the attack, the diagnosis of typhoid fever becomes justifiable, and the prognosis can be made with a high degree of confidence. Not often earlier than the second or later than the fourth week the fever will terminate, almost constantly by lysis, rarely by crisis. There are, however, exceptions, as shown by the occasional occurrence of death in walking typhoid and in other milder cases. Unquestionably, however, many cases of walking typhoid are never detected. They may often, if examined, exhibit characteristic symptoms, diarrhœa, rose spots, splenic enlargement, etc.; but in not a small number these signs are not discovered. The true nature of many of these milder cases is never recognized, and the pathological responsibility is thrown upon febricula, simple continued fever, gastric fever, bilious remittent fever, remittent malarial fever, etc. In the future a solution of the difficulty will be obtained through the knowledge derived from bacteriological research and culture-observations.

DISCUSSION.

Dr. William H. Draper, of New York, said that many cases in New York which have been diagnosticated as typho-malarial fever he considered to be cases of typhoid fever. The diagnosis of typhoid fever can be usually made in the course of the first week of the disease by attention to the characteristic course of the fever. The nervous symptoms of typhoid fever are also of great importance in the diagnosis. In considering a disease like this, it should be studied in its totality. His own experience confirmed that of others with reference to the use of quinine as an antipyretic in typhoid fever: that unless it is given in such doses as to produce a certain degree of collapse it is useless. He believed that it only increases the discomfort of the patient. If in five or six days the use of quinine does not succeed in checking the fever, we may conclude that we are dealing with a continued fever of the nature of typhoid.

Dr. John Guitéras, from an extended opportunity of studying these cases, both in the North and in the South, had come to a conclusion different from that expressed by the author. These cases present no symptom of typhoid fever with the exception of the continued fever, and this is a strong argument against their being typhoid. These cases are so numerous as we go farther South that he would class them as a separate disease. After examining post-mortem cases of prolonged continued fever, he had failed to find the lesions of typhoid fever. In the South we have, of these three diseases, malarial remittent fever at one end, typhoid fever at the other; and between these we have cases of the kind described by Dr. Atkinson. His view of this fever is that it belongs to the class of functional fevers. A simple continued fever may be set up by an excessive demand made upon any of the important functions of the body. He had thought that in warm climates, where constant exertion was required on the part of the heat-centres to keep within limits the production of heat, a paralytic condition of these centres might be induced, especially towards the close of a long and hot summer. This fever presents none of the symptoms of a

malarial affection, and is quite common in sections where malaria is unknown.

Dr. A. Jacobi, of New York, thought it a mistake to say that those cases in which the fever cannot be broken in five or six days by quinine are not malarial. There are cases of remittent fever that will not be broken by quinine. There is one assistance in diagnosis which he had not heard alluded to, and that is the urine-test. This has frequently been of much service to him. It is prepared as follows:

Solution No. 1: sodium nitrite, one part; water, two hundred parts.

Solution No. 2: solfanilin acid, five parts; concentrated muriatic acid, five parts; water, one hundred parts.

Add one and one-fifth parts of the first solution to fifty parts of the second.

Equal parts of this mixture and the urine are to be mixed. Then add about sixty or seventy per cent. of aqua ammoniæ. In normal urine there will be only a slight discoloration, while in urine from typhoid fever there will be a deep purple discoloration. This test is rarely applicable during the first two or three days. It generally can be applied up to the fifteenth or eighteenth day. It should also be stated that in cases of acute miliary tuberculosis the same reaction is obtained.

Dr. W. W. Johnston, of Washington: It is well known that in places where malaria has largely prevailed, as cities have grown and drainage improved malarial affections have diminished and typhoid fever has increased. This has been the case in Washington. It has also been observed in London. The cases of typhoid fever which he had observed may be arranged into three groups: those in which all the symptoms have been present, those in which only one has been present, and those in which all the symptoms with the exception of the fever have been absent. He could see no reason clinically for saying that these cases which do not present the typical temperature of typhoid fever are not cases of this disease. It is not necessary that the temperature should reach any special degree. Any temperature, provided it presents the typical curve, may be characteristic of typhoid fever.

Dr. R. H. Fitz, of Boston: An epidemic of an anomalous form of fever recently occurred in Boston among a number of emigrants. The diagnosis lay between typhoid and typhus fever. It was concluded that they were cases of typhoid fever. One case ended fatally. The intestinal lesions were of the most trivial character. The enlargement of Peyer's patches was no greater than is seen in many cases of enteritis. The lesions were so superficial that it seemed quite probable that they would have disappeared if the case had lived a few days longer.

Dr. Israel T. Dana, of Portland: Some of the cases to which Dr. Fitz has referred found their way to Portland, and one of them died there. The autopsy in this case showed well-defined but not complete lesions of typhoid fever.

Dr. W. J. Councilman, of Baltimore, said that he had expected to hear some allusion made to the examination of the blood as a means of diagnosis. A simple examination of the blood will enable us to differentiate between the continued malarial fevers and typhoid fever. The organisms found in these cases of continued malarial fevers are very easy to recognize. They are large crescentic forms, free in the blood and not contained in the corpuscles. They do not require a high power for their detection.

Dr. William Osler, of Philadelphia, agreed with the last speaker that we have in the microscopical examination of the blood a positive means of diagnosis. In doubtful cases, a careful examination of the blood will determine whether they are malarial or not; while a careful examination by culture-methods will determine whether or not it is a case of typhoid fever.

He mentioned three instances in which the examination of the blood aided in the diagnosis. One was a case of continued malarial fever thought to be typhoid; another was a case of remittent fever supposed to be typhoid. In both these instances examination of the blood showed the case to be malarial. In the third instance the patient had a chill, which was repeated. It was supposed to be a case of remittent fever, but the malarial organisms were not found. The case pursued an atypical course, and when two weeks advanced in convalescence had a well-marked relapse of typhoid fever.

Dr. I. E. Atkinson, of Baltimore, in concluding the discussion, said that he had been much interested in the remarks made by Dr. Guitéras. The cases reported were, he thought, cases of typhoid fever. He had never seen death in these atypical cases. That the cases of fever which occur in this locality, and which present the characters described, are really cases of typhoid fever, and not of malarial fever, was what he claimed in his paper.

At the final executive session, the report of the Committee on the Congress of American Physicians and Surgeons was received and adopted, and Dr. Wiliam Pepper, of Philadelphia (with Dr. Reginald H. Fitz, of Boston, as alternate), was appointed to represent this Association.

OFFICERS FOR THE ENSUING YEAR.

President.—Dr. William H. Draper, of New York.

Vice-Presidents. — Dr. Francis Minot, of Boston, and Dr. J. Palmer Howard, of Montreal.

Recorder.—Dr. William Osler, of Philadelphia.

Secretary.—Dr. Henry Hun, of Albany.

Treasurer.—Dr. W. W. Johnston, of Washington.

The following were elected to active membership: Drs. A. V. Meigs, Louis Starr, and J. H. Musser, Philadelphia; Dr. James E. Reeves, Wheeling, West Virginia; Dr. William H. Whitney, Boston; Dr. James Stewart, Montreal; and Dr. M. Allen Starr, New York.

Dr. John S. Billings, of Washington, was elected to honorary membership.

Adjourned.

BRITISH MEDICAL ASSOCIATION.

Fifty-Fifth Annual Meeting, at Dublin, August 2–5, 1887.

(Continued from page 810.)

DR. W. S. PLAYFAIR, F.R.C.P., LL.D., Professor of Obstetric Medicine at King's College Hospital, presented a paper on

THE PREVENTION OF PUERPERAL FEVER.

"The subject which I have the honor to introduce to you for discussion cannot fail, I think," said the Professor, "to interest those upon whom the responsibility rests of attending women in labor. The prevention of the scourge of midwifery practice, septicæmia, is one of the most important duties. In the short space of a quarter of an hour allotted me it will be impossible to do more than lay down a few general rules which should guide us. In lying-in hospitals, since the revolution of antiseptics, marvellous change has been effected. I am more particular to-day to insist on the prevention of puerperal disease in private and domiciliary practice. In the well-conducted lying-in hospital of to-day a woman is actually as safe, if not safer, than if confined at home in a large house and surrounded by all the comforts money can procure. The great Rotunda Hospital of this city, and the lying-in institutions of London, Paris, and St. Petersburg, as well as of other Continental cities, prove what I have said. There is nothing in the history of medicine more remarkable than the change in these institutions since the adoption of the life-saving principles of Lister. I doubt if such a thing can be found now as a hospital for lying-in in which antiseptic rules have not been adopted, and in which similar good results have not followed it. Though recognized and practised in public practice, I doubt if even yet antiseptic midwifery is at all general in private practice. Called to see septic cases as a consultant, I very seldom find that the practitioner in attendance has followed out the rules in such general use in lying-in hospitals. Perhaps when the younger class of practitioners get more into the work it will be different; but with the bulk of men now in practice no special care is taken. In civil practice similar care and precautions to those practised in institutions—a matter of no real difficulty to practise—should almost wipe this scourge out of existence. Pritsch daily dressed a putrid wound in the person of his brother for a whole year, and at the same time daily performed two or three obstetric operations, and by a vigorous antisepsis has not had a single case of septicæmia during the whole time.

"To show how simply this may be done and to elicit your views on this subject is my object to-day. I have no time for argument, and must perforce be brief and content myself with dogmatic statements. To prevent puerperal fever we must have an intelligent idea of what it is, how it originates, and how it may be conveyed to the patient. Unless we are agreed on these points, we are not likely to come to any conclusion of value. I take it to be now almost universally admitted that puerperal septicæmia is practically the same thing as surgical septicæmia,—a disease caused by poison absorbed through the genital tract into the system, which poison may either originate *de novo* or be conveyed to the patient from without by septic matter being brought in contact with her. We should manage her so as to reduce the chance of absorption to a minimum, closing as much as possible the channels through which septic matter is to be absorbed, by thorough and permanent contraction of the uterus, and by lessening absorptive surfaces offered by perineal lacerations and the like. How customary it is to find the binder hurriedly applied, with the uterus imperfectly contracted, remaining large and flabby underneath it, distended with clots, which frequently breed mischief! I practise and teach never to remove the hand from the uterus for at least twenty minutes after the removal of the placenta, keeping up a continuous though not rough rubbing or kneading. I believe it also good practice at this time to administer a large dose of ergot, and, if contractions do not set in, to make a hypodermic injection of ergotin or ergotinin. Personally I have never seen any harm result from the routine administration of ergot.

"As to perineal lacerations, I think the rule should be absolute that the perineum should be inspected after labor, and that every tear more than a slight laceration of the fourchette should be closed with catgut or wire sutures, first cleansing thoroughly with the bichloride of mercury solution, and subsequently dusting with iodoform night and morning. Thus any chance of absorption through the bared perineal surface is avoided, and complete healing is insured.

"Most important, however, are the antiseptic precautions by which we are to prevent the poison being introduced from without. This, indeed, is the essence of the whole matter. The vast majority of cases of puerperal septicæmia, to my mind, arise directly from poison carried to the patient by some prevent-

able accident. This is an unpleasant fact; but we must look unpleasant facts in the face. The nature of the medical man's work brings him constantly into contact with septic matter. There is no avoiding this. What we have to do is to take the precautions happily at our disposal to avoid the risk or reduce it to a minimum. The obstetrician, if he has much gynæcological practice, is especially in danger of infecting his patient. He has, in constant vaginal examinations, to imbue his fingers with vaginal discharges which may be of the utmost possible virulence, such as of uterine carcinoma. Many have infected themselves in this way through punctured wounds of the finger, and why not infect others?

"If I dwell on unpleasant topics such as these, my only object is to secure a thorough appreciation of their danger and its avoidance. The nurse has often, and justly, too, the blame to bear. She is constantly handling the genital organs at all hours for many days. Many of the older class of nurses persistently set themselves against the antiseptic precautions, 'new-fangled fads which they don't hold with.' If they are positively ordered to carry them out, they are apt to do so in the most perfunctory way. The tips of the fingers are just dipped into the antiseptic lotion. A sponge is used to wipe the genitals, and is put away unwashed or most imperfectly washed on a hot summer day. Quite recently I had occasion to use a catheter, and the nurse produced one belonging to her. I fished out of the eye a decomposing blood-clot, which had been lying there for days or weeks. Again, not long since I saw a most intense case of septicæmia; the nurse assured me that she had been most careful, and yet I found an under-sheet unchanged for four days, saturated with lochia, on which the patient was lying. In a hundred unsuspected ways such as these death may be conveyed to the patient. If, however, efficient antisepsis is to be carried out, the rules must be such as the nurse can understand, and not too complicated and troublesome to put into execution."

This is a copy of the card he gives to every nurse in attendance on cases under his charge.

"*Antiseptic Rules for Monthly Nurses.*

"1. Two bottles are supplied to each patient. One contains a solution of perchloride of mercury, of the strength of one part to one thousand of water, tinted with litmus (called the one to one-thousand solution); the other carbolized oil (one to eight).

"2. A small basin containing the one to one-thousand solution must always stand by the bedside of the patient, and the nurse must thoroughly rinse her hands in it every time she touches the patient in the neighborhood of the genital organs for washing or any other purpose, before or during labor, or for a week after delivery.

"3. All sponges, vaginal and rectal pipes, catheters, etc., must be dipped in the one-to one-thousand solution before being used. The surface of slippers, bed-pans, etc., should also be sponged with it.

"4. Vaginal pipes, enema tubes, catheters, etc., should be smeared with the carbolized oil before use.

"Unless express directions are given to the contrary, the vagina should be sponged twice daily after delivery with warm water, with a sufficient quantity of Condy's fluid dropped into it to give a pale pink color.

"All soiled linen, diapers, etc., should be immediately removed from the bedroom.

"N.B. These rules are for the protection of the patient from the risk arising from accidental contamination of the hands, or by sponges. It is therefore hoped they will be faithfully and minutely adhered to."

There is nothing complex in these rules. The details may be varied considerably as to the form of antiseptic employed, etc. It is the principle of antiseptics more than the details which is important. He prefers the perchloride of mercury to any other antiseptic, not only because of its acknowledged potency, but because it is bland and unirritating to the skin, and capable of being carried in a concentrated form and the solution made at a moment's notice. Nurses will not use a carbolic lotion, or use it inefficiently, because of its tendency to injure the hands, while he had never known one to object to the mercurial solution. He does not recommend it for vaginal injections after labor, because of a few cases of mercurial poisoning that have been reported to follow its use in this way.

There are a few precautions to be used during the labor for the physician himself.

1. Before making any examination or using the antiseptic lotion, he should thoroughly cleanse his hands with soap and water, being specially careful about his nails, under which septic matter may easily lurk.

2. At an early stage of the labor the vagina should once be thoroughly syringed with antiseptic lotion, and the vulva sponged with it.

3. When the head is distending the perineum, the external genitals should again be sponged with the solution.

4. Cold cream, lard, etc., should not be used for lubricating the fingers, but carbolized oil or vaseline employed instead.

5. When possible, sanitary towels should be used to receive the lochial discharges in preference to diapers, as they may be burned when soiled. All risk from imperfectly-cleansed diapers is thus avoided.

In conclusion he said, "I do not think these suggestions impose a grievous burden upon the practitioner who has the welfare of his patient at heart. There are many other points on which I might dwell if time allowed. One which seems particularly important is the duty of satisfying our-

selves of the sanitary condition of the house in which our patient is to be. It is but seldom, however, our opinion is asked on this point. Unfortunately, the public believes it is the duty of the physician to cure disease when it arises, not to prevent it. Meddling with such matters beforehand would be too often considered an unjustifiable interference. I am fully convinced that if a careful sanitary inspection were instituted before parturition, a great step would be taken towards attaining the object of this paper,—'the prevention of puerperal fever.'"

DISCUSSION.

Dr. Lombe Atthill, of Dublin, said he was a firm believer in septicæmia. The term puerperal fever he abhorred. It is caused by septicæmia. He was the first master in the Rotunda Hospital to require antiseptic precautions, which were then very imperfect. He had to undergo great opposition. Especially was this so with the nurses. It was indeed an effort to get them to part with their old, black, dirty dresses, and put on the uniform. They thought that to be compelled to wear such dresses as these in winter was nonsense. A relaxed condition of the uterus is a common cause of septicæmia. He remembered one patient who came into the Rotunda in labor. No physician was present at the time; but the nurse saw there was something the matter with her, and put her in a private ward, separate from the other patients. He was soon called, and found the patient to be suffering with erysipelas. She could not be put out of the house in labor, but after delivery she was sent to another place, only remaining in the hospital fifteen hours. There had been no case of puerperal fever for months before, yet there was one before twenty-four hours, and this was followed by several others, then they gradually disappeared. He thought, however, these were due to atmospheric conditions, and not to the presence of the woman in the hospital. Contamination in that case was hardly possible under the conditions. He believed that the preliminary treatment of puerperal fever will prevent puerperal fever in many cases. He did not believe that ergot given in a single dose will produce any effect. It should be given frequently.

Dr. M. T. Molony, Arklow, Ireland, said that in his city of six thousand inhabitants there had been an epidemic of scarlet fever for months. During this time there was no case of puerperal fever, and no approach to one. The scarlet fever was of a mild type, yet some cases were quite malignant. They had many cases of sore throat, some of them malignant, and some tonsillitis, etc. The town is the most unsanitary place on earth. As medical officer he attended most of the cases of labor, but used no antiseptics except on his forceps.

Dr. C. H. P. Routh, of London, thought that women in an unhappy state of mind (as those who had been seduced), as has been shown by Dr. Barnes, are much more likely to suffer with puerperal fever.

Dr. John M. Byers, of Belfast, was a thorough believer in the septicæmic view of puerperal fever. He asked, How can gentlemen maintaining views of other causes of puerperal fever explain the results of antisepsis in hospitals? Our nurses should be firm believers in antisepsis. Opinion is now going in the direction that the number of cases which are autogenetic is diminishing. The doctor then quoted from a paper by Dr. E. C. Linke, of Cincinnati, read before the American Medical Association in 1887, and published in the *New York Medical Record*, where the question of "How soon after exposure to infection can you attend a woman in labor?" was discussed and the opinions of prominent authorities were quoted. These opinions were at variance. It was a question he would wish answered.

Dr. Samuel Sloane, of Glasgow, said that antiseptics in the hospital in Glasgow have reduced the mortality very much. We cannot do without antiseptics. We should look more to antiseptic measures than we do. Close rooms in winter are more productive of puerperal fever than chills.

Dr. Moorman, of Edinburgh, thought the plan to stamp out puerperal septicæmia was a Utopian idea. How can we stamp out atmospheric conditions, lochial discharges, etc.? The patient should be prepared beforehand. She should be given the chloride of iron, quinine, potash, etc.; also ergot in small doses before labor is innocuous and acts beneficially. Is the prevention of puerperal septicæmia the function of the nurse more than of the doctor? It is not at all above the dignity of the obstetrician to look after the nurse. He closed by recommending uterine injections.

Mr. Lawson Tait said that, with Lombe Atthill, he abhorred the name of puerperal fever. The practitioners in his neighborhood had been giving him the opportunity to open the abdomen in cases of puerperal septicæmia, which operation was followed by good results. There are two kinds: one is systemic, and medicine and surgery are powerless; the other is local, and the patient can be saved. He had recently been called into the coroner's court to testify in a case where sixteen cases of puerperal fever had occurred in the practice of one man, all of which died. He inquired, and found that the most elaborate antiseptic precautions had been made and carried out. He did not inquire too closely, fearing to find out too much, but, after the trial, remembering that all the cases of puerperal septicæmia had been forceps cases, he asked him what precautions he had taken with his forceps. He replied, None. There was the whole secret.

Dr. H. Cameron, of Glasgow, had seen five

cases of puerperal septicæmia in one man's practice. He found that he had not been in the habit of disinfecting his forceps. He advised him to disinfect his forceps and burn his leather bag.

Dr. W. H. Humiston, of Cleveland, Ohio, said, If, as one gentleman has stated, puerperal fever is an epidemic disease, and occurs in waves without any assignable cause, why does it not now occur in the lying-in hospitals at Dresden, Prague, and Vienna? In these very same institutions, prior to the adoption of strictly antiseptic precautions, the mortality from puerperal septicæmia was appalling, ranging from ten to eighteen per hundred.

It had been his privilege to visit those institutions and observe their methods of conducting their obstetrical cases. They are most careful, and insist on the highest degree of cleanliness obtainable by frequent washing of hands and instruments with soap and water and antiseptic solutions. When Professor Leopold took charge of the Dresden Lying-In Hospital the mortality was thirteen per cent.; by strict antiseptic precautions it was brought down to *nil*, and has so remained for several years, not a case occurring within its walls.

One gentleman has asked how soon after having come in contact with septic material is a physician justified in attending a case of obstetrics. The reply was, at once, allowing time for change of clothes and thorough washing with reliable antiseptic solutions.

In Carl Braun's wards in the lying-in department of the general hospital at Vienna the assistant has charge of the wards, and takes personal charge of all complicated cases. At the same time he is daily giving operative courses upon the cadaver to students and practitioners, and the speaker had seen him summoned from the operative table in the pathological building to make a forceps-delivery. He would remove his overcoat and proceed to most careful washing of the arms and hands. The speaker never saw septic trouble arise in cases so managed.

One important point, which is original, and it is hoped will be found reliable in practice, is the indication that the specific gravity of the urine gives in foreshadowing coming disorder. If before and soon after delivery the specific gravity of the urine is markedly below 1020, look out for breakers ahead, for with the great amount of effete matter to be carried out of the system, if the elimination be sufficient the urine should be of high specific gravity.

Dr. A. V. Macan, of Dublin, said, We are all agreed that sepsis is a great danger after delivery. What is the relative danger of sepsis and other causes? If antisepsis reduce the cases so enormously, the great majority must be caused by sepsis. The remainder we will present to those who think there are other causes. It is a small present. Even in the heterogenic, sepsis must be introduced. He declared that allowing a nurse to go out to follow the calling after a three weeks' training, as is the case in London, is a disgrace to civilization. Here in the Rotunda we think six months little enough.

Dr. Playfair, in closing the discussion, said, Puerperal fever was not used in the paper, yet that term was heard again and again in the discussion. Cold and chill may produce a puerperal disease, but not puerperal septicæmia. No one is more fully possessed than himself with the idea of preparing a patient against puerperal septicæmia. The allotted time was far too brief to allow him to go over the whole ground. He did not believe that there ever was an epidemic of puerperal septicæmia. It does not come in this way. It is totally different from cholera and that class of diseases. This is a most dangerous theory. Puerperal septicæmia may be introduced through the atmosphere.

Dr. Arthur V. Macan, of Dublin, Master of the Rotunda Hospital, and President of the Section, made

THE ADDRESS IN OBSTETRICS.

After thanking the Section for the honor done him by electing him President, and welcoming the members to Dublin, and inviting them to make themselves at home at the Rotunda Hospital, the President proceeded to tell in what ways the practice of the Rotunda Hospital differed from similar institutions elsewhere. It was, first, the use of abdominal palpation in every case of labor, together with the practice of external version whenever necessary. Second, our time-honored and now almost universally adopted method of conducting the third stage of labor. Third, the application of antiseptics to midwifery. This he knew has been done with success in several other places, and, as it will be embraced by one of the subjects fixed for discussion, he need not here mention it. In regard to gynæcology, our practice differs from that of most of the teaching-centres in this kingdom in the systematic employment of bimanual examination, the patient lying on her back instead of on her side, the washing out and curetting of the uterus without previous dilatation of the cervix, and, lastly, the theories held as to the normal position of the uterus and the treatment of displacements of that organ which follow.

To begin, then, with the systematic lateral palpation of the abdomen in every case of labor. There are probably few in this company who have not experienced a feeling akin to despair at the difficulties to be overcome before the child's position, even in the least complicated cases, could be determined by vaginal examination. If the labor be protracted, and a caput succedaneum has formed, the diagnosis becomes almost impossible. He believed that a large number even of experienced practitioners used to content themselves

with diagnosticating whether the head presented or not, and never troubling themselves further. The position was too often that the woman was lying on her left side, the practitioner standing behind her, and the child placed upside down in the woman's abdomen. This made the mental process very complicated, so much so that the students were recommended by some text-books to cut the figure of an imaginary pelvis out of paper to assist them. All that is now changed, and any person with ordinary abilities can learn to make out the child's position after a very short apprenticeship. If then they are called on to deliver artificially they can do so intelligently. We can not only make out the position of the child, but we can also generally determine whether the child be large or small, what the quantity of liquor amnii is, and whether the birth be plural or single, and, probably the most important of all, we can determine whether the head be proportionate to the pelvis or not, by the projection of the head over the pubes and the extent to which it can be made to enter the front of the pelvis by firm pressure applied externally. Finally, there is no such school for learning the palpation of abdominal or other tumors as the palpation of the pregnant uterus.

He mentioned that we can often feel the arm of the child going out from the shoulder, while occasionally the elbow may be made out. In one case a hydrocephalic head was readily distinguished, in another the probability of the fœtus being anencephalic was foretold, while in one case the cord has been felt crossing the child's back, and quite recently we have thought that we have made out the placentic *situ* by the fingers being lifted off the child and the outlines being undeveloped.

To resume briefly, the points that can best be determined by the lateral examination are: 1st, the fact of pregnancy; 2d, the period of pregnancy; 3d, size of the child; 4th, condition of the bladder; 5th, axis of the uterus; 6th, condition of the abdominal wall; 7th, abnormal condition of the ovum, such as twins, hydrocephalus, anencephalus, hydatid mole, and frequently the life or death of the fœtus. Further, it directly leads to the practice of external turning, renders the finding of the fœtal heart simple, and generally enables us to estimate whether the pelvis be contracted or not. In these latter cases we also made out a low continuous murmur, like the uterine souffle, over the supposed placental *situ*. Of course, cases in which the placenta can be palpated will always be rare. To make them possible the placenta must be planted on the anterior abdominal walls, and the condition of the wall of the uterus, etc., must be favorable to palpation.

The step from the accurate diagnosis of the position and posture of the child to external turning is an almost imperceptible one. We can sometimes turn the child by the pressure of a couple of the fingers of one hand on the head. Such cases are exceptional, however, and the difficulty gradually increases with the tension and thickness of the abdominal walls, the fixation of the presenting part in the pelvis, and the passiveness of the patient, until we come to cases when we must first mobilize the presenting part by drawing it out of the pelvis from the abdomen or pushing it upward by the finger in the vagina, and, finally, to such cases where external turning even under chloroform is impossible. The cases in which we have found external turning of most importance, besides the mere rectification of a breech- or transverse-presentation, are cases of funis-presentation, whereby turning the funis may be carried on with the part presenting; also in cases of head-presentation with antero-posterior contraction of the pelvis when we wish to extract by the foot. With the head on the perineum and delayed labor, we can use a very great amount of force by pressure on the abdomen; in fact, we can get the whole weight of the body, almost, to bear on it. Suppose that much of this weight is lost by maldirection, we still have enough to very materially aid the progress of the case and lessen the number of forceps-cases. Schroeder has shown that it is want of power in the abdominal walls that delays the expulsion of the child. If the expelling force is a little less than the combined resistance, the child must, so to speak, remain forever in the same position. In such a case the addition of a single pound may be sufficient to expel the child. Further, the experience learned by palpation is a great help in the conduct of the third stage of labor, as it is much easier to rectify malposition before the strong uterine pains have set in. It is advisable for the woman to be examined some time, say a fortnight, before the estimated time of labor, in order to ascertain by the degree to which the head has entered the pelvis whether there be any disproportion or not. If there is much liquor amnii, and the child is very movable, we may expect malposition, and we should watch that we have the head well into the brim before the membranes rupture. The same may be said of prolapse of the cord. Having determined the position of the child, we find the auscultation of the fœtal heart very much easier.

Next as to the third stage of labor. As soon as the child's head is born, the hand is placed on the fundus of the uterus, the ulnar side looking towards the vertebral column, the palmar towards the axis of the uterus. The child's eyes are then carefully wiped, and a finger passed into the vagina to see if the cord could be around the child's neck. If the uterus does not expel the child, or it should make any exertion at respiration, pressure is made on the uterus, which is generally sufficient to cause the expulsion of the child. This subject received considerable attention.

Following down the uterus with the hand as the fœtus is being born, and keeping up a pressure until the placenta is expelled and the binder applied, has been the course pursued in the Dublin Lying-In Hospital since the membership of Joseph Clarke (1786–1793), and is now almost universally followed by all educated practitioners.—(McClintock's edition of Smellie's "Midwifery.")

On looking over Dr. Charles Johnson's ward-book bearing date of 1848 there is seen after numerous cases the terse statement, "Placenta pressed out." This was such common practice as to need no further explanation. If we consult Spiegelberg we will find that he accurately discriminates between the Dublin method and the then lately-introduced method of Credé, and gives his verdict entirely in favor of the former. Schroeder also accurately describes the two methods, and adopts entirely the Dublin method. We have, then, the curious fact that whereas in Germany the highest authorities are in favor of the Dublin method, in the latest English textbooks the writers recommend Credé's method, —or, rather, he would say, while describing and recommending the Dublin method they call it Credé's. As an Irishman, and the present Master of the Rotunda Hospital, he could not but hope that after this meeting of the British Medical Association this mistake may be corrected, and in the future the method may be known after the term in which it first saw light, as the "Dublin method."

The President then devoted some few words to the bimanual examination, strongly favoring the dorsal as compared with the lateral position. Such assertions as that this position was brutal or indecent he strongly denied.

Dr. M. Q. McCallahan, of Brailsford, read a paper on

A MONTH'S ABDOMINAL SECTIONS BY MR. LAWSON TAIT.

This consisted of a brief report of thirty-five abdominal sections, of course all recovering, —some of them almost snatched from the grave. Several were done for septicæmia.

Mr. Tait, who was present, said that the reports just read would show how he selected his cases. This cry about the selection of cases is an absolute falsehood. One case reported here was one he would certainly have been excused from operating. The woman was brought in in a state of collapse, almost dead. He had done three hundred laparotomies, with but two deaths, and he did not care to add another. He confessed that it was a temptation to refuse, but thought he must give the woman a chance for her life, slight as it might be. The result was wonderful. Suppose some one of our "tramp visitors" had come along and seen this case. He would have gone away, saying, "Lawson Tait is the most reckless operator I ever saw."

Dr. Robert Barnes, of London, expressed unqualified admiration of Mr. Tait and his results. He thought the surgery of the abdomen and that of the brain were epochs in surgery. He was glad to know that they were British productions, and that we are not indebted for them to the Germans.

Several other speeches laudatory of Mr. Tait and his methods were made.

A paper was read by Dr. Apostoli, Professor of Gynæcology and Electro-Therapeutics in Paris, in the Section of Obstetrics and Gynæcology, on his method of

ELECTRICAL TREATMENT OF FIBROID TUMORS OF THE UTERUS.

On account of the insecurity of surgical measures and the insufficiency of therapeutics, the doctor had been led to search for a method free from these evils. He had founded a method which he termed "Galvano-Chemical Cauterization of the Uterus." Electricity till now had not given the results hoped for, because it had been used in a vague and indefinite manner. By his method we have precision, energy, better localization, and thorough control. In bleeding fibroids he had come to consider the positive pole the medicament *par excellence.*

From galvano-puncture he feared bad results in the hands of the careless and uninstructed. He insisted upon the following precautions: absolute and regular antiseptic irrigation of the vagina after each operation; the punctures should be made with a small trocar or a needle, and should not exceed two centimetres in depth; they should be made in the most prominent part of the tumor, if possible in the posterior cul-de-sac; puncture should be made without a speculum; pulsation should be looked for, thus avoiding large vessels, and hemorrhage should be promptly stopped.

At the end of the paper he gave a statistical statement of his results:

"From July, 1882, to July, 1887, I have had under my care 278 patients with fibromas or hypertrophy of the uterus in some manifest degree, upon whom I have used 4246 applications of currents of electricity. The patients and operations may be thus classified:

"I. Clinique: 186 patients and 2347 operations,—1433 galvano-cauterizations, positive, intra-uterine; 593 galvano-cauterizations, negative, intra-uterine; 321 galvano-punctures, negative, vaginal.

"II. Private: 92 patients, 1899 operations, —1085 galvano-cauterizations, positive, intra-uterine; 746 galvano-cauterizations, negative, intra-uterine; 68 galvano-punctures, negative, vaginal.

"As I said before, I do not wish to convey the impression that all these patients have been cured. It is not so, for the reason that some of them have not persevered to the end, especially in the clinique, the attendance hav-

ing been discontinued upon the first feeling of amendment. But I can affirm that, where there has been no negligence, ninety-five times out of one hundred permanent benefit has been acknowledged. I may also predict that, if adopted in its integrity and worked out as it should be, the mortality henceforward will be nothing. The following is a report which gives occasion for melancholy comparison. Among the patients who had not the will to let me finish the work begun, and whose impatience led them voluntarily to seek the removal of their tumors by excision, seven put themselves into the hands of our most eminent surgeons, and not one of the seven recovered from the operation. Comment on this would be superfluous."

He said, in conclusion, "One word in parting. Men and their labors can in general only find their proper level and value through the esteem of their associates and the way in which their work is publicly accepted. If my method ever meets with the confidence of the profession (speaking now of England), it will be mainly due to your illustrious countryman, Sir Spencer Wells, who was one of the first to extend to me the benefit of his experience and authority, and to his learned friend, Dr. Woodman Webb, whose name will ever be coupled with its introduction and diffusion. It would be injustice were I not also to refer to the honor such distinguished gynæcologists as the Keiths (father and son), Playfair, Savage, Elder, and others have done me by their visits and the encouragement given me by their approbation. I cordially thank all who are present, and assure you that the best recompense of the work of my life will be to find many of you becoming my followers."

NOTES AND QUERIES.

COMMONWEALTH OF PENNSYLVANIA.

STATE BOARD OF HEALTH.

EXECUTIVE OFFICE, 1532 PINE STREET,
PHILADELPHIA, September 1, 1887.

A special meeting of the State Board of Health was held on Thursday, September 1, 1887, at the Executive Office, No. 1532 Pine Street, Philadelphia, to take action in reference to the death of the late President of the Board, Dr. Edward William Germer, of Erie, when the following resolutions were adopted:

Resolved, That this Board has heard with profound regret of the decease of its valued fellow-member and late President, Dr. Edward William Germer.

Resolved, That in a thorough and intelligent understanding of the principles of state hygiene, learned at the feet of Europe's earliest teacher in this most important branch of medical science, he had few equals, and in untiring energy, courage, and self-devotion in their practical applications in times of public danger no superior.

Resolved, That while the Board, in its official capacity, has lost an able, wise, and faithful member, whose whole energies were devoted to the good of the people, as individuals we mourn the departure of one whose endearing social qualities and warm emotional nature made him a delightful companion and a true friend.

Resolved, That copies of these resolutions be forwarded to the daily and medical press, and that a copy be sent to the bereaved family.

OFFICIAL LIST

OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U.S. ARMY FROM SEPTEMBER 4, 1887, TO SEPTEMBER 10, 1887.

LIEUTENANT-COLONEL JOSEPH R. SMITH, SURGEON.—Ordered to report in person to the Surgeon-General of the army on September 2, 1887, on business connected with the public service, and on completion thereof to return to his proper station. Par. 9, S. O. 198, A. G. O., August 26, 1887.

MAJOR C. C. BYRNE, SURGEON.—Detailed as a member of the Army Retiring Board in Washington City, *vice* Captain Washington Matthews, Assistant-Surgeon, relieved. Par. 2, S. O. 208, A. G. O., September 7, 1887.

MAJOR R. M. O'REILLY, SURGEON.—Ordered to proceed to Fort Niagara, New York, on public business, and upon completion thereof to return to his proper station, Washington, D.C. Par. 10, S. O. 205, A. G. O., September 3, 1887.

CAPTAIN H. O. PERLEY, ASSISTANT-SURGEON.—Ordered to accompany battalion of the Twenty-third Infantry from Fort Wayne, Michigan, to Chicago, to participate in the International Military Encampment to be held in that city in October next. Par. 1, S. O. 191, Headquarters Division of the Atlantic, September 8, 1887.

FIRST-LIEUTENANT W. B. BANISTER, ASSISTANT-SURGEON.—Granted leave of absence for one month, with permission to apply for extension of one month, to take effect upon arrival at Fort Lowell of Assistant-Surgeon J. B. Girard. Par. 4, S. O. 91, Headquarters Department of Arizona, August 29, 1887.

FIRST-LIEUTENANT WILLIAM N. SUTER, ASSISTANT-SURGEON.—Ordered to accompany Battery "E," Third Artillery, from Washington Barracks, D.C., to Philadelphia, on the 14th instant, to participate in the military parade during the celebration of the centennial of the adoption of the Constitution, September 15, 16, and 17, 1887. Par. 3, S. O. 191, Headquarters Division of the Atlantic, September 8, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U.S. NAVY FOR THE WEEK ENDING SEPTEMBER 3, 1887.

MEDICAL-DIRECTOR RICHARD C. DEAN.—Detached from duty as member of Examining and Retiring Boards, and to hospital at Chelsea, Massachusetts.

MEDICAL-DIRECTOR GEORGE PECK.—Orders as delegate to International Medical Congress revoked.

SURGEON M. H. SIMONS.—Detached from the "Constellation," and to the Naval Academy.

SURGEON B. F. ROGERS.—Detached from marine rendezvous, New York, and to the "Alliance."

ASSISTANT-SURGEON JAMES G. FIELD.—Detached from the "Vermont," and to marine rendezvous, New York.

ASSISTANT-SURGEON C. P. HENRY.—Ordered to the "Ossipee."

PASSED ASSISTANT-SURGEON G. P. LUMSDEN.—To the "Boston."

ASSISTANT-SURGEON LOUIS W. ATLEE.—Restored to duty.

There have been no changes in the Medical Corps of the Navy for the week ending September 10, 1887.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U.S. MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDING SEPTEMBER 10, 1887.

SAWTELLE, H. W., SURGEON.—Granted leave of absence for fifteen days, August 31, 1887.

CARMICHAEL, D. A., PASSED ASSISTANT-SURGEON.—Granted leave of absence for thirty days, September 5, 1887.

FATTIC, J. B., ASSISTANT-SURGEON.—Ordered to Cairo, Illinois, for temporary duty, September 6, 1887.

INDEX.

Abdominal operations, limits of, 399.
sections, 577.
Abortion in Paris, treatment of, 733.
Aconite, 332.
in the treatment of pneumonia, 332.
Aconitia in the treatment of nervous diseases, 363.
Actinomycosis hominis, 298.
Addison's disease in an infant, 299.
Adonidine in dilated heart, 557.
Air-passages, value of present methods of treating, 582.
Albumen, new test for, 131.
Albuminuria, 807.
some forms of, 298.
Alexander's operation, 427.
Allen, S. P., cold water in the treatment of typhoid fever, 795.
Alopecia areata, 748.
Althaus, Julius, on tetany, etc., 105.
American Medical Association, 629.
Amherst College, physical culture in, 332.
Amputation at knee-joint, new method of management of patella in, 794.
of mammary gland, 621.
Anæsthetics, the choice of, 351.
Andrews, T. H., fracture of skull, 378.
on the whipping-post, 10.
Aneurism, innominate, treated by simultaneous distal ligation of the common carotid and subclavian arteries—recovery, 496.
Angina pectoris, 572.
Anisic acid, 151, 332.
Announcement by the publishers, 824.
Anthracosis of lungs, 584.
Antifebrine, 24, 151, 628.
Antipyretic treatment of fever, 743.
Antipyretics, clinical value of, 791.
discussion on, 773.
Antipyrin and thallin, 49.
for whooping-cough, 669.
not to be given in pneumonia, 32.
Antipyrine, 628, 802.
Antiseptic appliances, 122.
pad, 549.
surgery, results of, 160.
treatment, 37.
Aphasia, a case of, 88, 112.
phthisis, and tubercular meningitis, 229.
Apostoli on electrical treatment of fibroid tumors of the uterus, 843.
on galvano-puncture in gynæcology, 380.
Arteritis complicating typhoid fever, 467.
Arthritic diabetes, 673.
Artificial feeding of infants, 457.
Asepsis at Pennsylvania Hospital, 127.
Ashhurst, Jr., John, on retention of urine, 493.
Astragalus, comminuted fracture of, 461.
Ataxic arthritis, 317.
Atropine, toxic symptoms from, 236.

Bacillus of typhoid fever, 672.
tuberculosis and the busy practitioner, 662.
typhosus, 92, 506.
